**Pontypridd.**—At a meeting of the District Council on Tuesday evening Mr. Teasdale, the resident engineer, reported that a trial trip of one of the new electric tramcars had been made in the Treforest district, and had been satisfactory. He hoped that the tram service would be inaugurated not later than March 7 where the lines had already been laid, and the electric lighting installed a week later. Colonel Druitt, the Local Government Board inspector, will inspect the system to-day.

**Erith.**—Good progress continues to be made with the construction of the electric tramways. The Urban Council have decided to inform the London County Council of the construction of tramways up to the county of London boundary at Abbey Wood, and to ask the County Council if they will proceed at once with the construction of the tramways authorised in the last session of Parliament from Abbey Wood to Plumstead, so as to form a through connection with this Council's tramways system.

**Newcastle.**—At a meeting of the Tramways Committee last week it was agreed, in dealing with the estimates, that the track should not be anchored except in such places and such times as the track is up for the purpose of repair. Consequently the sum of £4,500 included in the estimates for the purpose of anchoring and welding the joints will stand over for further consideration. It was decided that the chairman should have an interview with the Tyneside Tramways Company, and make arrangements for increasing the service from Newcastle to Wallsend, having a five minutes' service instead of 10 as at present.

**North Staffordshire Railway.**—At the half-yearly meeting of this company the Chairman stated that, in order to cope with tramway competition, the company had ordered two motor-coaches to run upon rails which they intended to experiment with. It was proposed that these coaches should be put upon the rails and run through the populous districts, stopping at various places which were not regular stations, so that they might pick up passengers. The first route on which they intended to experiment was from Silverdale to Trentham, and if they found the experiment was a success they would, no doubt, follow it up.

**Plymouth.**—At the meeting of the Corporation a member criticised the tramway accounts, pointing out that the receipts in the period dealt with had increased by only £1,225, while the expenditure had increased by £2,983, and drawing the deduction that the tramways were less prosperous. It was explained that the expenditure included a considerable sum for the repair of the permanent way. In adopting a report authorising the construction of the line from Pound-street to Pennycomequick, a rider was added to the effect that wood block paving should be used as far as possible, the estimated extra cost to be first approved by the Tramways and Finance Committees.

**London County Council.**—The Council have come to an arrangement with the Metropolitan Water Board under which the latter are to provide a water supply in the event of any portion of the Council's condensing plant temporarily breaking down. The receipts for the week ended Feb. 4 amounted to £12,556, against £9,373 last year, and from April the total was £562,616, against £437,128. The agenda of the Fulham Borough Council for Wednesday contained a recommendation that support should be given to the County Council's scheme for trams along the embankment. The Battersea Borough Council have decided to urge the County Council to proceed more expeditiously with the electrification of the trams in the district.

**Swansea.**—The necessary steps have been taken to promote the Corporation Bill this session, and the company intend offering the strongest opposition to Part II., which seeks powers to acquire the tramways subject to a lease to the company for 21 years. An opening for a possible compromise is to be offered, however, as the tramways directors will be invited to a conference with the Parliamentary Committee of the Corporation. A basis for a working arrangement has been informally suggested, consisting of an arrangement for pooling the receipts for the whole of the tramways, whether owned by the Corporation or the company, and the division of profits for a period of between 30 and 40 years, after which the Corporation would acquire the company's tramways at "their constructed values," without any liability to grant a further lease.

**London Road Car Co.**—At the meeting of this company it was stated that cars were being built for the company with a 36-h.p., which would carry 34 passengers, and which were being exhibited at the present time at Olympia. It was intended that the substitution of mechanical traction for horse power would be carried out gradually, the existing horses and cars being disposed of by degrees, as a charge to revenue, as they were replaced by the rolling-stock. To provide for the difference in the cost of the new motor road cars and the value in the books of the present fully-equipped horse cars, it was proposed to issue the balance of the company's share capital (£116,004), and, in accordance with the terms under which the capital was authorised, the issue was, in the first place, offered to the shareholders. As the substitution of the motorcars for the present cars would be a gradual one, the additional capital would not be required all at once. The response to the Board's circular had provided sufficient capital for present requirements.

**Motor Omnibuses for London.**—Messrs. Hicks, Davis, and Hunt, solicitors to the London Omnibus Owners' Federation, address the editor of the *Times* as follows: "In view of the interest now being taken by the general public in motor omnibuses, the London Omnibus Owners' Federation will be obliged if you will allow them to announce through you the fact that the undermentioned companies and firms already working omnibuses in London have at this moment a very large number of motor omnibuses under construction, and that they will be in actual work during the next few months; and, further, that it is their intention to cover the whole of the roads with motor vehicles at an early date: London General Omnibus Company, Limited; London Road Car Company, Limited; Thomas Tilling, Limited; Associated Omnibus Company, Limited; Birch Bros., Limited; P. Hearn; Atlas and Waterloo Association; Star Omnibus Company, Limited; London Omnibus Carriage Company, Limited; C. W. French and Sons; Philips and Brickland; Camden Town Association; Victoria Omnibus Association."

**District Railway.**—At the meeting of this company last week, Mr. R. W. Perks, M.P., who presided, said he could almost positively assure the stockholders that that would be the last meeting which the company would hold while the line was being worked by steam traction. The Board was confident that before they met in July next the whole of the steam locomotives would have disappeared from the railway, and the whole of the main line and branches would be worked electrically. The reason why they were not working so now was that the foreign and British car builders had not carried out their contracts to time. The two English companies were building 280 cars, and 140 were being made on the Continent, but they were all considerably behindhand in delivery. Trains were now being delivered by the English contractors, and he hoped that within two or three weeks the foreign companies would begin delivery. Mr. Perks has been succeeded as chairman by Mr. Charles Yerkes, who informed the meeting that he intended to give all his time and energy to the District Company, for he wished it to be the crowning success of his life.

**Private Bills.**—The following petitions have been deposited in the Private Bill Office of the House of Commons: Against the Baker-street and Waterloo Railway Bill—Petition of the Pelican and British Empire Life Office and the Phœnix Assurance Company. Against the Central London Railway Bill—Petitions of the trustees and manager of the Stock Exchange, Union Bank of Scotland, Lloyds Bank, Union Discount Company, Commercial Union Assurance Company, Union Bank of Australia, Scottish Widows' Fund, National Discount Company, Mutual Life Insurance of New York, Liverpool, London, and Globe Insurance Company, County Fire Office, and Provident Life Office. Against the Great Northern, Piccadilly, and Brompton Railway (No. 2) Bill—Petitions of Union Bank of Scotland, Lloyds Bank, Union Discount Company, Commercial Union Assurance Company, Union Bank of Australia, Scottish Widows' Fund, National Discount Company, Union Assurance Company, Liverpool, London, and Globe Insurance Company, Mutual Life Insurance of New York. Against the Hammersmith, City, and North-East London Railway Bill—Petition of Bank of British North America.

**Aston.**—At a special meeting of the Town Council held on Friday last the Council adopted a report of the Public Works Committee embracing a scheme which had been prepared by their consulting engineer, Mr. Robert Green, for the reconstruction of the remaining tramways within the borough, including street improvements. The total cost of the work, including the overhead electric equipment, is estimated to cost £63,270. The Council approved the plans and sections of the work prepared by the engineer, and authorised tenders to be obtained. At a special meeting of the Town Council the members considered the report of the Public Works Committee submitted at the last meeting with regard to the reconstruction of tramways in High-street, Six Ways, Birchfield-road, Lozells-road, and

Digitized by Google

Witton-road. The committee did not intend curtailing the width of any of the footpaths of the routes affected. It was proposed that the tramway in Lozells-road should be paved with wood, that that portion of the route between Chain-walk and Whitehead-road should be paved with wood, and the remainder with granite setts. The committee also recommended, with regard to the making-up of High-street after the construction of the tramways, that the road should be paved from end to end, and that the portion between Six Ways and Whitehead-road should be paved with wood, and the remainder with granite setts as far as New-street, and from New-street to the city boundary with wood. The report was approved.

**Belfast.**—At the meeting of the Finance Committee on Monday the Lord Mayor reported as to the result of the negotiations carried on in London by the members of the committee to whom the raising of a loan for the tramways and other works had been entrusted. He detailed the terms under which the loan had been guaranteed by the Union of London and Smiths Bank, Limited, these being an issue price of 98, bearing interest at 3½ per cent., with 1 per cent underwriting commission and the usual brokerage charges, the net result of which is that the Corporation will get the money at about 3¾ per cent. The loan will amount in all to £1,000,000, of which £900.000 will be for the tramways, while the remaining £100,000 will be devoted to other purposes. The arbitration proceedings between the Corporation and the company are proceeding, Mr. Macassey acting as umpire. The company's claim totals close upon £400,000. For permanent way the Corporation put the figure at £105,000. Practically all the quantities and such like matters have been agreed, and the main question to be decided is the extent of the depreciation of the undertaking, the company putting the life of the rails at 24 years, and the Corporation insisting that 18 years are ample. The company are represented by Mr. Cripps, K.C., M.P., Mr. Richardson, and Mr. Hutchinson. Counsel for the Corporation are Mr. Balfour Browne, K.C., and Mr. Campbell, K.C., M.P., Solicitor-General for Ireland. Mr. Cutler, the city surveyor, tendered evidence on behalf of the Corporation as to the condition of the permanent way.

**North-Eastern Railway.**—Speaking at the half-yearly meeting of this company, Sir Edward Grey, the chairman, stated that before the electric trains were introduced the first-class passengers only represented 2 per cent. of the whole of the public travelling on that part of the system. Where the proportion of traffic was so small as that, and where a more frequent service was given, it was quite impossible to provide for this small section without some sacrifice of economy in working. But it was very undesirable that there should be a degree of friction and heat which made the working of the railway difficult, or impaired their relations with the public. Where the inconvenience had been proved to be real the Board desired, even by some sacrifice of economy in working, that it should be dealt with. Though they could not revert to the accommodation first provided for first-class passengers, they proposed to devise some method by which at any rate some first-class accommodation should be provided on the ordinary trains. Considering all the difficulties of the change, the Board thought they had met with a certain amount of unreasonableness in the demands made upon them. The financial result had so far been satisfactory. There had been an increase in receipts of £17,000, equivalent to 27 per cent., and after deducting working expenses, interest on capital and depreciation, they considered that there was a certain net profit left on the working of the electric trains. The Board saw no reason why the future of electric train working should not be as satisfactory as hitherto, but they did not propose to found upon the short experience they had so far had further demands on the shareholders for large capital expenditure, though they believed that the results they had got up to now would be confirmed by future experience.

## LIGHTING AND GENERAL.

**Gravesend.**—Application is to be made for sanction to borrow £4,500 for extensions of mains.

**Handsworth.**—The District Council have decided to borrow £45,000 in connection with the electric lighting scheme.

**Rawtenstall.**—The draft of proposed agreement between the Corporation and the Lancashire Electric Power Company has been agreed to.

**Holyhead.**—The Urban District Council are raising £13,700 for electric lighting purposes and £3,300 for the destructor works, at 4 per cent. per annum.

**Irvine.**—At a public meeting on Wednesday a resolution was carried dissenting from the action taken by the Town Council in the matter of installing electric light into the burgh.

**Tiverton.**—At the last Town Council meeting it was proposed that the electric lighting order be rescinded. A desultory discussion ensued, and the Mayor declined to put the motion.

**Hove.**—Hove proposes to follow Brighton in the method of charging for electricity at Aldrington. Sevenpence a unit for the first hour, and 4d. per unit after, are the prices in view.

**Oxford Electric Co.**—The directors recommend a dividend of 7 per cent. for the year ending Dec. 31, free of income tax, including the interim dividend of 2½ per cent. paid in September last.

**National Telephone Co.**—The transfer books of preference shares and preferred and deferred stocks will be closed from Feb. 15 to 28, both days inclusive, for payment of the dividend for the half-year ended Dec. 31.

**Beckenham.**—The Urban District Council have referred to their General Purposes Committee the report on the advisability of being connected with the telephone system, of which, it appears, Bromley is the nearest station.

**Auckland.**—The Cleveland and Durham Electric Power Company have informed the Urban District Council that negotiations for the transfer of the provisional powers have now practically been brought to a satisfactory conclusion.

**Brompton and Kensington Electricity Co.**—The directors have declared a dividend for the half-year ended Dec. 31 last at the rate of 11 per cent. on the ordinary shares, making, with the interim distribution, 10 per cent. for the year.

**Lichfield.**—The City Council are petitioning against the Shropshire and Worcestershire Electric Power Bill, which proposes to include Staffordshire and the boroughs of Lichfield and Tamworth, with the view of getting protective clauses inserted.

**Nelson.**—The sale of the Corporation's old plant, consisting of two engines and dynamos at the old electricity works, has been completed. Alderman Hudson and the electrical engineer are to report on the advisability of fixing superheaters to the boilers at the electricity works.

**Huddersfield.**—Last July the Electricity Committee reduced the electricity rates, and now they have decided that the charges for current be reduced by ½d. per unit. At the same time they are transferring £5,985 from the revenue and contingencies accounts to the borough fund in aid of the rates.

**Coatbridge.**—The Town Council have decided to consent to the granting of the order being promoted by the Scottish House-to-House Electricity Company, Limited, to transfer their undertaking on the County of London Electric Supply Company guaranteeing the carrying out of the transfer on the lines indicated in the draft agreement.

**Farnham.**—The Council's recent resolution giving a conditional consent to the grant of a provisional order to the Farnham and District Electric Supply Company, Limited, has been rescinded, and, subject to an undertaking being given by the company that their works shall be situated within the urban district, the Council will consent to the grant of the proposed order.

**Yarmouth.**—Messrs. Preece and Cardew will act as consulting engineers in regard to the extension of the electric lighting installation, estimated to cost £10,000. The lighting of the Marine-parade South with arc lamps has been agreed to. The annual cost will be £90, and the Electricity Committee have decided to lay the necessary mains and fix the requisite posts at a cost of £420.

**Gillingham.**—A total of 13,321 8-c.p. lamps, with 220 consumers, is now connected to the Corporation's mains. The resident engineer's estimates of the cost of laying down public and private lighting mains in various roads will be considered when the final financial statement, including the loan for £19,754, comes before the committee. The question of free wiring has been adjourned for the same cause.

**New Firm.**—We are informed that Mr. Robert McLaren, who has been engaged for many years in the locomotive department of the Central Argentine Railway, has now joined the firm of Topping and Seavill, engineers, Rosario, and in future the firm will trade as Topping, Seavill, and McLaren, engineers; and agents in the Argentine for J. and H. McLaren, Midland Engine Works, Leeds.

**Stourbridge.**—The Guardians are still undecided whether to light the new workhouse by gas or by electricity. The architect (Mr. A. Marshall) has submitted estimates, and these were £2,700 for electric fittings and £2,139 for gas fittings for the workhouse. The price for electric lighting would be 3d. per Board of Trade unit, and 2s. per 1,000 for gas if a minimum of three million feet were consumed yearly.

**Stock Exchange.**—The Stock Exchange Committee have appointed Feb. 23 special settling day for Marconi's Wireless Telegraph Company's further issue of 30,016 shares of £1 each, fully paid, Nos. 196 112 to 196,127 and 221,128 to 251,127. Application has been made to the committee to appoint a special settling day in and to grant a quotation to Havana Electricity Company's scrip (fully and partly paid) for £150,000 5 per cent. debentures.

**Galashiels.**—The Electric Lighting Committee are satisfied with the recent canvass with regard to prospective consumers for electric light and power. Under advice of Messrs. Handcock and Dykes, it has been agreed that an agreement be entered into with a company to carry out the installation, and otherwise implement the whole obligations of the Corporation under the order, on the basis of the company providing the whole capital required.

**Exeter.**—At the last meeting of the City Council Mr. Munro protested against the proposal to entrust the management of the electrical equipment to the Electric Light Committee and the electrical engineer. He moved the rejection of the recommendation. The electrical engineer (Mr. H. D. Munro), said he desired enquiry. Nine members voted for Mr. Munro's amendment, which was lost. An amendment that the Council hold an enquiry in committee before the question of the management of the electrical equipment of the tramways was decided on was carried.

**St. Marylebone.**—The Electric Supply Committee last night submitted the following statements: (1) Estimated revenue statement to March 31, 1905—Expenditure—interest on loans and accruing due to March 31, 1905, £38,225; expenses of obtaining loans, £2,381; rents, rates, taxes, insurance, and repairs, £1,103; salaries, wages, and general establishment expenses, £821; supply of current, £600; law and parliamentary charges, £98; cost of promotion of Bills of 1901 and 1904 (proportion of), £1,096—total, £44,324. Income—interest from Metropolitan Electric Supply Company, Limited, £37,035; bankers' interest on temporary deposit, £283; rents of various properties, £956; debit balance, £6,050—total, £44,324. (2) Estimated revenue statement, March 31, 1905, to Sept. 30, 1905—Expenditure—interest on No. 1 loan, £24,765; ditto No. 2 loan, £937; ditto No. 3 loan, £469; ditto bank balances, £100; rents, etc., payable (less rents receivable), £200; salaries, wages, etc., £700; general expenses, £200—total, £27,369. Income—interest from Metropolitan Electric Supply Company, Limited, £21,369; ditto balance, £6,000—total, £27,369.

Digitized by Google

**Dewsbury.**—The amount of current used for power and lighting during the fortnight previous to Jan. 21 amounted to 27,871 units, or 3,500 units more than last year, while the supply for tramways was greater by 2,800 units. These figures fully justify the reduction which has been made in the charges for electric lighting.

**Change in Dundee Telephones.**—The Town Council have agreed to the National Telephone Company's proposal to put in underground conduits practically the remaining portion of the overhead telephone wires of the city. The work of opening up and reinstating the streets will be carried out by the Town Council at the expense of the company, who will have to remove all overhead wires where they cross tramway lines.

**Louth.**—At the quarterly meeting of the Town Council, the Electric Lighting Committee reported having made enquiries as to the costs of and the results obtained by having producer gas as a motive power, and had resolved to ask the engineers to submit an alternative estimate for the cost of a suitable plant driven by producer gas. It was decided that the minutes be referred back to be presented to the Council in committee.

**Worcester.**—At the last meeting of the City Council, the Electricity Committee reported a loss on the undertaking in the past year of £1,220. Mr. Parker said that it had been the worst year experienced in regard to water power, and instead of receiving £3,500 from the tramway company, the revenue from that source had been only a little over £2,000. It was urged that the water power obtainable at Powick should be exploited to its fullest extent.

**Walsall.**—The report of the Electricity Committee shows a successful year. After paying the interest and sinking fund there remains a profit of £1,060, but the committee have also been able to reduce the price of electricity from 6d. to 4d., and that used by the trams from 2d. to 1½d. Several extensions of the electric mains are now to be carried out at a total cost of some £1,800 to £1,900. The profit of £1,061 will be carried to the reserve fund.

**Heywood.**—The consumption of electricity for the month of December, 1904, was 9,345 units, as against 8,216 units for the corresponding period of last year, showing an increase of 1,129 units. The consumption for the quarter ending December was 24,531 units, as against 21,139 units for the corresponding period of last year, showing an increase of 3,412 units. The chairman and vice-chairman have been authorised to purchase new motors required during the ensuing year.

**Wakefield.**—The City Council have decided to apply for sanction to borrow £18,000 for extensions in connection with the electrical undertaking. The electricity department is paying over this year £900 towards the rates, and £200 towards the expenses of the town hall. The committee also intend to reduce the price for electricity from 4½d. to 4d. per unit, as well as to abolish the meter rent, which would mean a difference of £600. They thus show a profit of £2,200, as they will still hold £500 in hand.

**Dunfermline.**—The Town Council have apparently only just found out that their proposed application for a provisional order anent electric lighting and power must stand over till November. The resolution was passed on Thursday by the Town Council on the assumption that the application would be made in March. Provisional arrangements have been made for a meeting with representatives of the Fife Electric Power Company with the object of ascertaining the lowest terms on which the company will supply electricity in bulk.

**Huddersfield.**—The last accounts of the Corporation's electricity undertaking show a surplus of £3,875. The surplus, together with £2,110, from the depreciation and contingency account, is to be transferred to the borough fund in aid of the rates for 1905-6, by way of reducing the amount received from the borough rates towards deficiencies in the revenue account for the three years 1893-4-5, amounting to £5,985. 16s. 6d. If this proposal is adopted, the depreciation and contingencies fund will be reduced from £11,853. 11s. 7d. to £9,743. 0s. 1d.

**Mexborough.**—An enquiry has been held into an application of the Urban District Council for sanction to borrow a further £4,000 required for necessary extensions in connection with the electric light undertaking. The money is required to meet deficiencies on the former loans, and to complete new work already sanctioned by the Board but not carried out. The expenditure in excess of the previous amounts scheduled includes £1,359, cost of new cables and lamp. Cables had been laid in certain streets not scheduled, absorbing a further £488, making the total excess £1,847. On the other hand, £1,110. 15s., allowed for mains in the first application, has not been spent.

**King's Lynn.**—During the month applications have been received for 93 additional lamps of 8 c.p. (or equivalent), making a total of 20,427 from private consumers, an increase of four. Enquiries whether the Corporation are willing to let out motors on hire or hire purchase are under consideration. The following report has been submitted—viz.: units generated, December, 1904, 61,501 (1903 59,014); total units sold to private consumers (light and power), 29,765 (25,326); units sold at power rates, 10,091 (5,629); cost of fuel, stores, repairs, and wages at stations, £152. 13s. 5d. (£156. 7s. 6d); cost per unit generated, 0·5955d. (0·6356d.); wages of lamplighters and outside staff, £20. 11s. 4d. (£22. 12s. 10d.).

**Hammersmith.**—The premises of 13 additional consumers, representing a maximum of 315 8-c.p. lamps, have been connected to the mains; 10 consumers have been disconnected, the present number of consumers taking current from the mains being 1,537. The Guardians have received a letter from the Local Government Board requesting that the specification and schedules on which the electric lighting tenders for the workhouse and infirmary buildings were based might be submitted to them, together with the plans indicating the position and number of lights proposed to be introduced. At the last meeting directions were given for the necessary papers to be obtained and forwarded to the Local Government Board.

**Swansea.**—The members of the Corporation paid their annual visit to the electric lighting station on Friday. The Chairman (Major Sinclair), in referring to the progress that had been made, said he certainly anticipated they would come out well on the right side, and that as time went on their position would steadily improve. He believed they had got a really good thing in the electrical undertaking, and one which, in spite of the critics, would soon come under the heading of remunerative undertakings. He thoroughly believed, from what he had seen and knew, that the interests of the public were being well looked after.

**City of London Electric Lighting Co.**—The directors have decided to transfer the sum of £45,500 to reserve account, and to recommend to the shareholders the payment of the following final dividends for the year ended Dec. 31, 1904: Preference shares—0s. per share, making with the dividend of 6s. per share paid in July, 1904, a total distribution of 12s. per share, being at the full rate of 6 per cent. per annum, subject to deduction of income tax. Ordinary shares—7s. per share, making with the dividend of 5s. per share paid in July, 1904, a total distribution of 12s. per share, being at the rate of 6 per cent. per annum for the year 1904, subject to deduction of income tax. The above appropriations will leave a balance of about £22,000 to be carried forward.

**London Gazette.**—George Walter Chapman, official receiver, Bankruptcy-buildings, Carey-street, London, W., has been released from trusteeship in the estate of George Neale, electrician, 2, Fulham Palace-road, London, and trading with another at such address as the South-Western Electrical Contracting and Maintenance Company. Thomas Henry Geake, official receiver, 6, Athenæum-terrace, Plymouth, has been released from trusteeship in the estate of David Todd Cameron, mechanical and electrical engineer, 1, Magdala-villas, Saltash, Cornwall. The partnership between William Hampson and Montague Wakefield Wickes, electrical engineers, 8, Harrington-street, Liverpool, trading as the Liverpool Electrical Engineering Company, has been dissolved by mutual consent.

**Dundee.**—At a meeting of the Tramway Committee the question of the erection of a new electrical station for the city was discussed, but no resolution was proposed. The Electrical Engineer said that during the past winter there had been a large increase in the use of electricity for lighting, involving an additional demand of 900 h.p. If this increase continued, the question of a new station would have to be faced. Mr. Brownlee said they had at present plant to supply 5,000 h.p., and there was boiler space for another 4,000 h.p. The coolers for the condensers could be put on the roof. A suitable place would be the esplanade, near Magdalen-green Station. They would then be close to the river for water, and they could have a railway siding for coal. To have a station near the railway and the river would mean a saving of about £3,000 per annum. He doubted if the Harbour Trustees would sell the dock.

**Telegraph Poles.**—The Staffordshire County Council have just concluded a bout with the Post Office with reference to the placing of telegraph poles by the sides of the main roads. From the beginning the Council insisted that a condition of their consent to the erection of the poles should be that the main roads surveyor should approve of the sites. The Post Office superintendent engineer, in declining to furnish the plans, said that "the positions proposed would naturally be those most suitable to the Department's point of view, and I venture to suggest that these would be hardly likely to meet with the approval of your Council's surveyor." In reply to that the clerk said he should advise the Council to decline to issue any consent, and leave the Department to their remedy, or to issue the consent "subject to the position of the poles being to the satisfaction of the Council's surveyor." Thus the Department would run the risk of his objecting to the position and requiring it to be altered. The matter was referred to the Postmaster-General, and he has now agreed to accept the condition that the poles should be erected subject to the Council's surveyor approving of the positions.

**Science on the Stage.**—A pretty and effective application of the thermit process will be utilised next week in the bill of the London Pavilion, when Miss Lu Robinson will demonstrate, by means of various small crucibles, how iron can be manufactured in a few seconds without the aid of a furnace. By the courtesy of Mr. Frank Glenister, the manager of the London Pavilion, Limited, we were enabled, on Wednesday, to witness a private representation of the turn. Miss Robinson commenced by pouring a small quantity of black grain, which, she explained, did not contain one particle of metallic iron, into a 3in. crucible, added a saltspoonful of white powder, applied a match to it, and almost immediately afterwards, by the aid of a magnet, withdrew from it a solid piece of wrought iron. Large quantities were made and turned into moulds, and thus a horseshoe was turned out within a few seconds. Although the heat engendered comes up to that of an electric furnace, the process is so quick that the crucibles have no time to get heated, and, in fact, one experiment was made inside an ordinary silk hat which had been previously filled with sand, and which was not in the least heated by the process. By the same means a hole was burnt into a solid iron plate in about two seconds, and Miss Robinson was careful to inform the audience that also by these means a safe might be burgled. Mr. William Sykes would have to be mighty quick about it, or else he would burn the contents of the safe as well. Various pretty displays of fireworks, amongst which was an artificial arc lamp, produced by the burning of a steel spring inside a glass cylinder.

**Brighton Telephones.**—A report was presented at last night's meeting of the Town Council showing the excess in telephone expenditure, and recommending application for power to borrow the amount required (£11,616) and a further sum for extensions at Hove. The Corporation telephone system is now showing a profit of £80 per

Digitized by Google

month. The report of the Telephones Committee is as follows:—The Telephones Committee have received the following report from the engineer and manager with reference to expenditure in excess of the provision made in Mr. Bennett's estimate, and also with reference to the estimated cost of providing additional ducts and cables in the borough of Hove, which are urgently required to meet the requirements of subscribers in Hove: "Corporation Telephone Department, Brighton, Feb. 2, 1905. To the Telephone Committee of the Town Council of Brighton. Gentlemen,—I have to report that the following work has been done in excess of what was intended in Mr. Bennett's estimate: Additional work sanctioned by the Council on April 7, 1904—extension of ducts in Preston-road and Upper Lewes-road, £1,195; extension of cable and laying same, £3,013. 5s. 6d.; building switchroom (Mr. Bennett allowed £550 for adapting a room to exchange requirements, but did not anticipate that such extensive alterations would be necessary; the cost has been £1,137. 16s. 2d.), difference £587. 16s. 2d.; power-room, £94. 7s. 1d.; power plant, £99. 10s.; cable and ducts beyond Clermont-road in Patcham parish, £216. 12s. 6d.; cable and ducts at Portslade, £30; cable at Southwick and Kingston, £60. 18s. 2d.; ducts laid by Hove Corporation in Church-road, Hove (and now used by this department), amount due to the Corporation £394. 2s. 3d.; difference in cost of switchboard between original tender and actual cost, owing to order being given first for 1,000 lines, and afterwards extended to 2,000 lines when prices had gone up, £525—total, £6,216. 11s. 8d. I therefore recommend that you apply to the Local Government Board for sanction to a loan to defray the cost of the extension of the ducts and cable, amounting to £4,208. 5s. 6d., and also £2,008. 6s. 2d., the cost of the other works enumerated above. You have at the present time 1,687 instruments working and 22 junction lines, making a total of 1,709 completed lines. In addition to which you have 1,229 partially completed lines, making a total of 2,938 completed and partially completed lines. I have also to report that in the borough of Hove 259 lines have been provided, and you have 186 instruments working on these lines. There are a number of others in Hove working on the Brighton cables. There is now such a small number of spares that it is imperative that you should supplement the underground cables in Hove at once and in every direction. I have prepared a scheme to provide 312 additional lines in Hove (being for 200 completed lines and 112 spares). The cost I estimate will be £5,399. 11s. 5d. I therefore recommend you to apply to the Local Government Board for sanction to a loan of £5,400 to defray the cost of these extensions. I am pleased to be able to say that although you have not yet got the 2,000 lines working on which your revenue was estimated to yield a profit, the net profit (after allowing for sinking fund and interest on the money borrowed, and all other charges) is now at the rate of £80 per month, and every month it is increasing. The profits thus earned will enable the Council to establish a substantial reserve fund.—I am, gentlemen, your obedient servant, (signed) D. J. BARNES, engineer and manager."

## PROVISIONAL PATENTS, 1905.

FEB. 6.

**2268. Electric working of mine shafts.** James Swinburne, 82, Victoria-street, Westminster, London.

**2299. Improvements in and relating to electroliers and electric wall brackets.** George Shilvock, 67A, Corporation-street, Birmingham.

**2313. Electrical dental furnace.** Luther Lawrence Bosworth, 52, Chancery-lane, London. (Complete specification.)

**2328. Improvements in apparatus for heating water electrically.** Milton Henry Shoenberg, 60, Queen Victoria-street, London. (Complete specification.)

**2339. Improvements in electric machines.** William Asahel Johnson, 4, South-street, Finsbury, London. (Complete specification.)

**2341. Improvements in brush-rocking gear for dynamos.** Henry Leitner and Harry Hill, 4, South-street, Finsbury, London.

**2342. Improvements in electric lighting of trains.** Henry Leitner and Richard Norman Lucas, 4, South-street, Finsbury, London.

**2351. Improvements relating to apparatus for telegraphic purposes.** Joseph Theodor Szek, 22, Southampton-buildings, Chancery-lane, London.

FEB. 7.

**2387. Improvements in electrical switches.** John Alexander Kennedy McGregor, 5, Corporation-street, Birmingham.

**2401. Improvements relating to the starting and control of direct-current electric motors.** William Henry Heath, 18, Southampton-buildings, Chancery-lane, London.

**2426. Improvements in electrical resistances.** H. Ward Leonard, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**2432. Improvements in electric systems.** Horace Dowie, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**2474. A new or improved process for neutralising static electricity.** William Henry Chapman, 18, Buckingham-street, Strand, London. (Complete specification.)

**2475. Improvements in automatic systems of signalling for electric railways.** Samuel Marsh Young, 18, Buckingham-street, Strand, London. (Complete specification.)

**2490. Improvements in methods of insulating the windings of dynamo-electric machines.** The British Thomson-Houston Company, Limited, and Siegfried von Ammon, 83, Cannon-street, London.

**2491. Improvements in thermal cut-outs or fuses.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

FEB. 8.

**2495. Improvements in apparatus for the automatic ignition of gas, gaseous mixtures, or the like by means of an electric current.** George Hill, The Grove, Ashton-on-Mersey. (Complete specification.)

**2506. Improvements in or relating to the trolley pulleys of electric tramcars.** James Nicholas Hicks and Michael Galvin, 55, Market-street, Manchester.

**2529. Improvements in electric stop-motions for drawing, slubbing, intermediate, roving, and like frames.** Edmund Tweedale and Samuel Tweedale, Penny Bank-chambers, Halifax.

**2533. An electric high and low water level indicator for water-tube boilers.** Jens Ernest Schmidt, Solheim, Hill-grove-crescent, Kidderminster.

**2545. Improvements in the electrical regulation of clocks.** Frederick Augustus Chandler and Bahne Bonniksen, 18, Hertford-street, Coventry.

**2554. Improvements in or relating to electrical connections.** Paul Hallot, 78, Fleet-street, London. (Complete specification.)

**2559. Improvements relating to electric ignition apparatus.** Sir Oliver Joseph Lodge and Alexander Marshall Lodge, 18, Southampton-buildings, Chancery-lane, London.

**2579. An improved protector or casing for electric conductors, pipes, or the like.** Otto Wilhelmi, 40, Chancery-lane, London. (Complete specification.)

**2581. Improvements in homopolar dynamos.** Henry Leitner, 4, South-street, Finsbury, London.

**2586. Improvements in electric switches.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

FEB. 9.

**2607. Improvements in fusible cut-outs.** Herbert Henry Berry and Sidney Mark George Teal, 78, Upper Thames-street, London.

**2628. Improvements in electric ignition arrangements for explosion motors.** Alfred Schoeller, 100, Wellington-street, Glasgow. (Complete specification.)

**2632. Improvements in or relating to burnishing tools for use in the electro-deposition of metals.** Joseph Christopher Jobling and Herbert Champion Harrison, 50, Wellington-street, Leeds. (Complete specification.)

**2639. Improvements in electrical lampholders.** Edward Bettridge Boucher, 21, Finsbury-pavement, London.

**2658. Electric lighter.** Arthur Charles Cann, 59, Victoria-grove, Stoke Newington, London.

**2673. Improvements in apparatus for the periodic making and breaking of an electric circuit suitable for use in connection with electric lamps and other electric apparatus, horological instruments, and for other purposes.** Guy Carey Fricker, 46, Lincoln's-inn-fields, London.

**2691. Improvements in electric signalling systems and apparatus therefor.** The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (The General Electric Company, United States.)

**2692. Improvements in and relating to electric arc lamps.** Edwin Rudolph Grote and Milton Victor Ely, trading as Foster and Co., Palace-chambers, 9, Bridge-street, Westminster, London.

**2693. Trolley pole controller.** Stephen Edward Gunyon, 115, Cannon-street, London. (The Magney Manufacturing Company, United States.) (Complete specification.)

FEB. 10.

**2715. Improvements in connection with pendants, brackets, and the like fittings for gas, oil, and electric lighting, and for similar purposes.** Arthur Woodhouse Southgate and Frank Southgate, 104, Colmore-row, Birmingham.

**2723. A new and improved system of running and insulating electrical conductors.** Harold Sheen Martin and George Vose Stavert, 22, Sir Thomas-street, Liverpool.

**2742. New or improved apparatus for distributing electric currents or producing electric pulsations.** Arthur Thomas Milnor Thomson and Glendower Owen Ellis, Norfolk House, Norfolk-street, London.

**2747. Improvements in electric cables.** Charles James Beaver and Ernest Alexander Claremont, 4, Bloomsbury-square, London.

**2749. Time element maximum current thermal device for cut-outs, alarms, or indicators.** Frank Biliotti, 8, John-street, Adelphi, Strand, London.

**2766. Improvements in locks and switches for gates of electrically-controlled lifts.** Charles George Major, Edwin Charles Stevens, and Percy Herbert Stevens, "Janus" Works, Queen's-road, Battersea.

Digitized by Google

2789. **Improvements in protective devices for electric circuits.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

FEB. 11.

2816. **Improvements in and relating to the automatic lubrication of trolley wheels for overhead system of electric traction.** Lewis Jonathan Bedford, 2, Thistle-villas, Reading-street, St. Peter's, Kent.

2850. **Improvements in connection with electrostatic watt and watt-hour meters.** Ernest Wilson and William Hamilton Wilson, 64, St. John's-park, Blackheath, London.

2862. **Improvements in protective devices for electric apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

2864. **Improvements in installations for controlling electrically-propelled trains.** Siemens Bros. and Co., Limited, and Charles Frewen Jenkin, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

2871. **Improvements in or relating to hermetically-enclosed arc lamps, such as are known as electric vapour lamps, partly applicable to other electrical purposes.** Charles Orme Bastian and George Calvert, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published March 2.*

1904.

2644. **Clutch coupling or means for detachably securing arc lamps to their hangers or suspending or supporting posts, pillars, or the like.** Donovan.

2939. **Electrical igniting appliance for explosion engines.** Bullock and Roehl.

3072. **Cut-outs for overhead electrical conductors.** Nash and Eschus.

3386. **Electric motor-control systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

3919. **System of speed regulation for electromotor-driven machinery.** Dunn. (Date applied for under International Convention, Aug. 20, 1903.)

7418. **Hydrometer for use with electric storage batteries.** Hutton.

7489. **Metallic conduits for electric light cables and the like.** Waterhouse and Simplex Steel Conduit Company, Limited.

8549. **Electric ships' telegraph.** Houston and Erskine.

8555. **Electric stop-motions for drawing, slubbing, and other similar machines for preparing and spinning cotton and other fibrous materials.** Tweedale, Tweedale, and Smalley.

13927. **System and apparatus for electrically operating bulkhead doors, hatches, or the like.** Jones. (Long-Arm System Company.)

16820. **Electric winding-up device for clocks and other chronometrical instruments with or without striking work.** Sallin.

19168. **Alternating-current electrical machinery.** Thompson (Berliner Maschinenbau Akt.-Ges. vorm. L. Schwartzkopff.)

26948. **Storage batteries.** Mills. (Edison.)

27011. **Vapour electric apparatus for rectifying electric currents and other purposes.** Kruh. (Date applied for under International Convention, Dec. 12, 1903.)

27755. **Counting mechanism, more especially intended for use with electricity meters.** Aron and Runge.

27887. **Vapour electric apparatus for wireless signalling and other purposes.** Weintraub. (Date applied for under International Convention, Dec. 21, 1903.)

28453. **Continuous-current electric motor.** Soc. Anon. pour le Travail Electrique des Metaux. (Date applied for under International Convention, May 10, 1904.)

28628. **Arc lamps.** Rosemeyer.

29307. **Switches for electric incandescent lamps.** Frey.

29386. **Electrical generators having double-shaped armatures.** Gutzmann.

## NOTES.

**The Institution.**—It has been decided to hold an extra meeting on Thursday next, when Mr. Donald Murray's paper, "Setting Type by Telegraphy," will be discussed.

**Manchester Section.**—This section has decided to hold its annual dinner at the Midland Hotel, Manchester, on Friday, the 10th prox., the charge for tickets being 7s. 6d. It is desired that applications for tickets should be made before the 28th inst., so as to allow time for the necessary arrangements.

**Hull Tramways.**—The recreation club in connection with the electrical engineer's department of the Hull city tramways held their first smoking concert in the Manchester Hotel on Friday last. Mr. J. Wilkinson, tramways manager, was in the chair, supported by Messrs. W. T. Robson (chief assistant engineer), D. Joys, T. Palmer (secretary), and others. In a few well-chosen remarks the chairman said that the future of the tramways in Hull was very bright, and when the proposed extensions were finished would be the means of giving employment to a number of men. The toast of "The Mayor" (Alderman T. Larard), who is president of the club and chairman of the Tramways Committee, was given with musical honours. During the evening the large audience was entertained to a capital variety programme. From the attendance, which numbered some 250, this new club seems likely to be a success.

**New Atlantic Cable.**—It is reported from New York that before many months the Commercial Cable Company will lay its fifth Atlantic cable, the work being undertaken by the Silvertown Company or the Telegraph Construction Company, of London, or by these two companies conjointly. This appears to have caused some discontent in the States, which resulted in Mr. George Ward, vice-chairman of the Commercial Cable Company, paying a high tribute, when interviewed a few days ago, to English cable companies. His company, he stated, were not lacking in patriotism, but the plain truth was that there was no American cable company so well equipped for the task in question as their English rivals, which have complete facilities for the manufacture of cable as well as steamships specially designed and manned for the work of laying cables. The new cable will run from Nova Scotia to Ireland, a distance of 2,300 miles, and is estimated to cost over £450,000.

**Large Gas-Engines.**—Dr. Louis Bell, in his *résumé* of the "Electric Railway Situation" in the *Electrical Review* of New York, refers to a radical innovation about to be made in San Francisco, where the California Gas and Electric Corporation has just ordered three 4,000-kw. three-phase generating sets, each driven by a 6,000-h.p. gas-engine. These are stated to be for operating the street railways of the city. All sorts of reports are current about the performance of the big gas-engines now used in this country, the majority of them rather unfavourable, but the engineers of this large corporation seem to have been convinced that the gas-engine is all right. It has been looming large in the background for some time, and its appearance at the front of the stage will be watched with the greatest interest. In conclusion, the author disclaims the power of prophecy as to whether this new departure will be successful, but if it be so, the battle of the engines, long impending, will be on in deadly earnest.

**Wireless Telegraphy in the Red Sea.**—It is reported that the wireless telegraph station which has been under construction for some time by Lloyd's at the Red Sea extremity of Suez is expected to be in complete working order about the middle of March, when wireless communication will for the first time be practicable with ships in the Red Sea, as well as throughout the entire course of the Suez Canal. This will doubtless prove no small boon to shipping in cases of accident or distress. In regard to the transmission of "Marconigrams"—or, to give them their official designation, "radiograms"—to vessels crossing the Atlantic, it is announced that during the first three or four days after the vessels leave Liverpool the messages will be sent from Poldhu direct to the steamer. During the next three or four days the messages will be forwarded by cable to the North American Continent, and repeated thence to the approaching ship. An extra 1s. per word is charged for messages which have to be repeated from the other side to cover the cost of the cablegram. At present, however, only the Cunard mail steamers are fitted with long-distance apparatus.

**Lighting New York.**—The City Fathers of New York, like those of Paris, have been a good deal exercised in their minds of late as to whether a municipal electric light supply shall be given, the public having expressed a good deal of dissatisfaction with the company's tariff. It is reported that at a conference between the civic leaders the idea of a municipal lighting plant obtained an adverse reception. The project was viewed with favour in the first instance, but the eagerness displayed by Tammany, which is still a factor to be reckoned with, caused visions of a legion of overpaid superintendents, inspectors, engineers, etc., to present themselves to some of the leading citizens. Consequently this measure is likely to be abandoned, or to encounter a good deal of opposition if proceeded with. A section of the American Press, while holding that there is a good deal of room for reform in the public services of New York, recommends caution in entering for a municipal supply, and hints that the local authorities of England have met with very qualified success in such enterprises. It is stated that a compromise may be arrived at by the city obtaining power to purchase current and distributing it over wires which it has authority to lay in the conduits of the Consolidated Telegraph and Subway Company.

**Leeds Section.**—The Leeds Section of the Institution of Electrical Engineers inspected the electric light and power works of the Shipley Urban District Council on Saturday. The visitors were conveyed from Bradford to Shipley and back by special car by courtesy of the Bradford Tramways Committee. Mr. R. Lindley (chairman of the Shipley Electricity Committee) and Mr. Schofield (resident engineer) met the party, and conducted them over the works. The site of the present works was originally intended for sewage outfall and destructor works alone, but it was decided to combine the electricity works and dust destructor, so as to utilise the steam for generating energy. The electricity supply was commenced on July 26, 1899, with only three consumers; for the year 1904 the units generated totalled 985,988, so the great progress of the undertaking can be seen at a glance. It was pointed out to the visitors as a feature of interest that although the design and arrangement of plant exhibited no startling innovations, the undertakers had adopted a definite attitude in regard to three debatable matters: (1) the whole of the generators are driven by steam-turbines; (2) superheating is employed; and (3) the combination of dust destructor with electricity works. After tea the visitors discussed the design and equipment of the Shipley works, which were considered to be of an up-to-date character.

**Water-Tube Boilers.**—It is stated that the German Admiralty has now decided to entirely dispense with cylindrical boilers. They are the last of the first-class Powers to adopt exclusively water-tube steam generators. The tubular type has already been employed in many

Digitized by Google

ships, but in combination with the cylindrical boiler. In fact, Germany was among the first to adopt the duplicate system, at one time preferred by the British Navy Boiler Committee, but subsequently departed from in favour of he complete installation of Babcock and Wilcox or Yarrow boilers. The type so far favoured in Germany is the Schultz, now associated with the Thorneycroft, which it closely resembles. It is also reported that the question of retaining the treble-screw propeller, which most of the other Powers have discarded, has been under consideration. The German engineers admit that this propeller confers no economy, and that even if the centre engine gives better thermo-dynamic results under certain conditions, the drag of the side propellers nullifies this gain; but the naval architects regard it as of the highest importance that there should be three separate water-tight compartments for the machinery so as the better to ensure that the vessel will always have one of her engines in action. On this ground all new ships, including the two new battleships and an armoured cruiser soon to be laid down, will have three engines and three screws.

**Chelsea.**—The Chelsea Borough Council, it seems, applied some time ago for sanction to borrow £29,000, the total estimated cost of erecting public baths in King's-road, including the provision of s self-contained electrical installation, mainly for lighting purposes. Having held an enquiry into the matter, the Local Government Board now suggest that it would be more economical if the Council purchased the electricity required from an existing source. No doubt money is often wasted by municipal authorities in needlessly duplicating plant rather than lend support to private enterprise, but in the present case there is at least some excuse for difference of opinion—how much it would be impossible to decide without weighing all the factors. However, assuming the baths to be necessary, boiler power must, of course, be installed. Granted that, the idea of providing a slightly larger heating surface than would be necessary for primary requirements only, and adding a small generating set with storage battery, does not seem extraordinary. But the question to consider is whether the extra capital outlay and increased cost of maintenance would be justified by estimated results—taking the price charged per unit for the available supply of electricity as a basis for comparison. No doubt the Local Government Board have gone pretty carefully into the matter, in which case their reported judgment must be taken as a compliment to the local supply company.

**New Publications.**—"Mechanical Appliances, Mechanical Movements, and Novelties of Construction," by G. D. Hiscox (London: Archibald Constable. 12s. 6d.). This is a useful encyclopædia of mechanics, and should be serviceable to draughtsmen, students, and patent agents. Mr. Hiscox is the author of an earlier volume, entitled "Mechanical Movements," which has passed through 10 editions, but the present treatise is of a somewhat more advanced character.—The February number of the *Electric Club Journal* (Pittsburg, Pa.) contains as its frontispiece an illustration of the 5,500-kw. turbo-generator described in the opening article. There is an article entitled "Armature Winding for Constant-Potential Direct-Current Machinery," and Mr. C. F. Scott deals with "The Induction Motor and the Rotary Converter, and their Relation to the Transmission System." Mr. C. E. Skinner gives "Some Hints about Transformer Oil," and "Cable Splicing" is dealt with by Mr. W. Barnes, jun. Messrs. H. W. Peck, E. H. Dewson, R. E. Workman, and V. Karapetoff continue their respective serial articles on "Modern Practice in Switchboard Design," "Electric Railway Braking," "Factory Testing of Electrical Machinery," and "Applications of Alternating-Current Diagrams."—"Gas and Oil Engines," by W. C. Runciman (London: Percival Marshall and Co. 6d.). The latest addition to this well-known series of interesting little handbooks provides the amateur with a handy guide to the operation of these engines.

**Electrical Engineer Volunteers' Bohemian Concert.**—The Electrical Engineer Volunteer Corps held another of their famous entertainments last Friday at the Horns Assembly Rooms, in the shape of a Bohemian concert, which was probably the most successful the corps has yet achieved. Captain O'Shaughnessy, the president of the Entertainment Committee, presided, and was assisted by Lieut. Shepherd and Sergeant-Major Marshall on behalf of that committee. Among the officers present we noticed Captain Leaf and Lieutenants Merritt and Levin. A very attractive programme was gone through, Mr. Percy C. Taylor presiding at the piano. The vocal performances were exceptionally good, and included songs and duets by Miss H. Jenkins Colyer and Mr. Murray Rundsey, and the Misses Daisy Wiltshire and Florence Maynard. Comic songs, recitations, etc., by Sapper F. H. Shove, Corporal J. H. Brinkworth, and Mr. Charles Wreford were also very much appreciated. During the interval Sergeant-Major Marshall, president of the sergeants' mess, on behalf of that body presented Mr. Edgcumbe, of the headquarter's staff, with an elegant silver tea service on the occasion of his marriage. Corporal Vitty was the recipient of the monthly spoon-shoot prize. The scarlet of the members of the corps, sprinkled here and there with the blue of the various artillery, cavalry, and naval units of the auxiliary forces, together with the lighter-hued costumes of the large number of ladies present, gave the hall, with its broad and lofty vista, unbroken by pillars or roof supports of any kind, and its effective electric cornice lighting, a very brilliant aspect.

**British Association.**—We published some information last week anent the association's programme for the meeting in South Africa next August, which we are able to supplement from an announcement in the Johannesburg *Star*. At the invitation of the British Association, the South African organisation have nominated the following gentlemen as vice-presidents and secretaries of the 11 sections for the meeting in Johannesburg: Section A—Mathematics and Physical Science—vice-president, Dr. Breyer; secretary, R. T. A. Innes. Section B—Chemistry—vice-president, J. R. Williams; secretary, W. A. Caldecott. Section C—Geology—vice-president, Dr. Corstorphine; secretary, Dr. Molengraaff. Section D—Zoology—vice-president, Dr. Gunning; secretary, Dr. Pakes. Section E—Geography—vice-president, E. H. V. Melvill; secretary, F. Flowers. Section F—Economic Science and Statistics—vice-president, S. Evans; secretary, Robert A. Ababrelton. Section G—Engineering—vice-president, S. Jennings; secretary, E. Williams. Section H—Anthropology—vice-president, Dr. Schonland; secretary, A. von Dessauer. Section I—Physiology—vice-president, Sir Kendal Franks; secretary, A. Mackenzie, M.D. Section J—Botany—vice-president, Burtt Davy; secretary, Prof. Pearson. Section K—Educational Science—vice-president, E. B. Sargant; secretary, Prof. Hele-Shaw. In addition to the sectional meetings, the presidential address by Prof. Darwin, president-elect of the British Association, will be delivered in Johannesburg; and a number of public lectures will be delivered during the week by the following gentlemen: Prof. E. B. Poulton, on "Burchell's Work in South Africa"; Prof. J. O. Arnold, on "Compounds of Steel"; Mr. A. R. Hinks, on an astronomical subject; Sir William Crookes, on "Fluorescence"; Mr. F. Soddy, on "Radio-activity"; Mr. A. E. Shipley, on a zoological subject; and

Digitized by Google

Mr. C. V. Boys, on physics. The formation of a general reception committee and a number of sub-committees has been decided upon, as stated last week.

**Institution of Mechanical Engineers.** — The annual report of this institution, which was presented at a meeting last Friday, shows that the total number of members at the end of 1904 was 4,477, representing a gain of 266 over the previous year. The revenue for the year was £11,049, while the expenditure was £10,406, leaving a balance of £643, exclusive of entrance fees and life compositions to the amount of £611, carried direct to capital account. The first report, by Prof. David S. Capper, to the Steam-Engine Research Committee, has now been completed, and, together with a preliminary report on progressive speed and pressure trials carried out previous to March, 1896, will be presented at the March meeting. Since the presentation, in January, 1904, of the late Sir William Robert-Austen's last report, the Alloys Research Committee, under the chairmanship of Sir William H. White, has continued its work at the National Physical Laboratory. Dr. Glazebrook, directory of the laboratory, has arranged a series of investigations on specimens of nickel steel presented by Mr. R. A. Hadfield. It is anticipated that a further report will be presented this year by the committee, communicating the results of these researches. Prof. F. W. Burstall reports that the two specially-constructed large gas-engines and a gas-holder erected in the new power-house of the Birmingham University are now available for the Gas-Engine Research Committee's experiments. The series of experiments on initial condensation in steam-cylinders, which Prof. T. Hudson Beare is carrying out with special apparatus, are in active progress, but are as yet incomplete. Allusion is made to the joint meeting with the American Society in Chicago, and to the monthly meetings held throughout the session, at which a number of excellent papers were presented. The graduates also held monthly meetings and paid various visits.

**The Telephone Position** —The speculation so long rife in relation to the acquisition by the Government of the National Telephone Company's undertaking was removed on the evening of the 16th inst., when the Postmaster-General laid on the table of the House of Commons a memorandum embodying the terms of an agreement entered into by him with the company, the text of which we give in another column. Lord Stanley assured the House some time ago that he would not enter into any final arrangement without consulting Parliament, and the memorandum concludes with the statement that "the agreement will become binding when confirmed by a resolution of the House of Commons, or on Aug. 31 if not disapproved by Parliament before that date." It will be seen that the agreement is practically on the same lines as that entered into in 1901 with reference to the London area, the Government acquiring the company's undertaking at the end of 1911, on paying the value of the plant *in situ*—*i.e.*, on what are commonly called "tramway terms" — which represents a tolerably good bargain for the country. There will, however, be an allowance for goodwill in respect of the company's private-wire business, and in the few cases where the company's license has been extended beyond 1911. Presumably the price is to be settled by arbitration if the parties cannot agree, but it is to be hoped that when the time for fixing the amount arrives a figure will be arranged voluntarily, so as to obviate the expense and delay of protracted arbitration proceedings. With the basis of the transaction clearly defined by the agreement, this course should be quite feasible. In the meantime the company are to allow intercommunication without additional charge between the systems of the Postmaster-General and of the company. If, on complaint and after full enquiry, it is proved that the company is giving an inefficient service in any district, the Postmaster-General may take over the company's business in that district at once, without any payment for goodwill. It is notified that the Postmaster-General will probably take into the Government service when the transfer is effected a "considerable proportion" of the company's officers and servants, on terms to be agreed, but the Postmaster-General will not recognise any liability for pension or compensation in respect of service under the company.

**Tramways and Light Railways.**—A Board of Trade return issued on Wednesday as a parliamentary paper, gives some interesting statistics in relation to the growth of tramways and light railways. The return covers the period from 1878 down to Dec. 31, 1903, in the case of companies, and to March 31, 1904, in respect of local authorities. The report deals with three epochs, classified as the periods of animal, steam, and electric traction. The maximum year of the horse period was 1879, and that for the steam period 1898, while the use of electric traction is, of course, still growing. As compared with the year 1878 the length of line open has increased from 269 miles to 1,840 miles in 1903-4; the capital expenditure from £4,207,350 to £46,451,444; the number of passengers carried from 146,000,000 to 1,799,000,000, and the net receipts from £230,956 to £2,912,110. The capital expenditure per mile of single track open on all items was in 1879, the horse period, £9,877; in 1898, the steam period, £10,469; and in 1903-4, the electric period, £16,018. The percentage of net receipts to capital outlay rose from 3·97 in 1879 to 6·38 in 1898, and in 1903-4 was 6·27; the percentage of working expenditure to gross receipts was in 1879, 83·81; in 1898, 76·93; and in 1903-4, 66·15. The number of passengers carried per mile of route open during 1903-4 was 977,951, as against 806,703 in 1898, and 469,641 in 1879. This again illustrates how improved services create new traffic. The average fare per passenger was 1·84d. in 1879, 1·23d. in 1898, and 1·11d. in 1903-4. The length of line open on the London County Council's southern system at March 31, 1904, was 40 miles, and the receipts for the year were £536,239, the working expenditure £443,986, leaving a profit of £92,253; while the number of passengers carried was 133,139,085. The London United Tramways Company in the same period had 30 miles of line open, and the receipts were £280,241, the expenses £176,391, leaving a profit of £103,850; the number of passengers carried was 45,293,473. The North Metropolitan line, leased from the London County Council, had 50 miles of line open; the receipts were £330,821, the expenses £311,818, leaving a profit of £19,003, the number of passengers carried being 68,154,670. In 1898 there were 38,777 horses and 589 steam locomotives employed on the tramways. In 1903-4 there were only 15,353 horses and 249 steam locomotives. The places of those which have gone have been taken by 7,132 electric cars, so that over 1,460 miles of tramway and light railway line are now worked by electric traction, and only 235 under horse and 108 under steam. Of the total of 312 tramway and light railway undertakings in the United Kingdom, 162 are now owned by local authorities, with a total of 1,147 miles of track. A total capital expenditure of £28,060,524 has been incurred by local authorities. From the profits of these municipal undertakings a sum of £207,087 was in 1903-4 handed over to the relief of the rates, prominent among the contributors being Leeds, Manchester, Liverpool, Glasgow, Nottingham, Salford, and Hull.

**Electricity in Agriculture.**—A method of subjecting the soil, trees, or plants to an electric current for the purpose not only of destroying insects, but at the same time of charging the soil with ozone, is described in the *Western Electrician* of Chicago. With this object a patent has been obtained by Mr. Sigismund Lokuciejewsky, of Odessa. The source of current may be a storage battery or a generator capable of providing either direct or alternating current. In the latter case the generator is mounted upon a wheeled frame as shown in Fig. 1, so that the armature will be rapidly rotated. The current is first led through an interrupter, 5, and after passing the rheostat, 10, enters the transformer or induction coil, 6. The current is directly led back thence to the opposite pole of

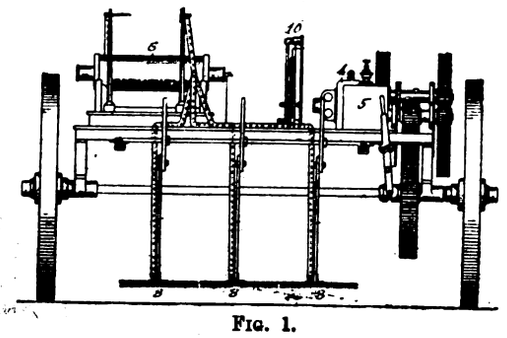

FIG. 1.

the generator, 4. Thus a current of high tension and frequency and low density is produced in the induction coil. One electrode takes the form of an implement arranged to either slide on the surface of the soil or tree or to cut into the soil. As shown in Fig. 2, a circular disc, 7, is employed for this purpose, the disc being attached to the frame of the car so that it will cut into the soil according to the degree of its adjustment. The other electrode consists of brushes, 8, which are fixed to the lower ends of rods or levers, enabling them to be brought in contact with the surface of the soil or tree. The current flows from the transformer through the disc into the soil and through the soil to the other electrode, passing, in the form of sparks or rays, from the soil to the brushes, and then back through

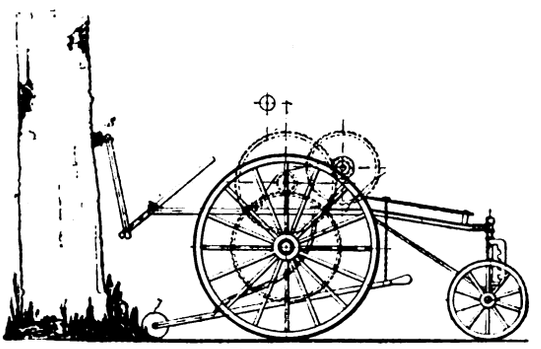

FIG. 2.

conducting wires to the transformer. It is stated that all insects and larvæ in the soil through which the current flows are destroyed, and that the soil becomes "ozonified." To destroy insects on trees the brush electrode is moved by hand along the trunk or branch, and the other electrode is introduced into the soil near the tree, thereby subjecting the insects to the current. The apparatus is intended to be so arranged as to give, at a potential of 500,000 volts, a current of ·0000005 of an ampere. Trials are stated to have proved that these high-potential and low-density currents do not injure the plants, and that they increase the fertility of the soil.

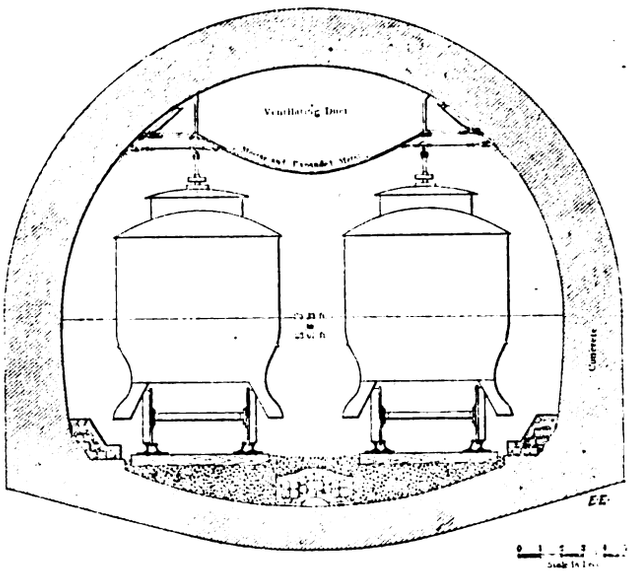
**Electricity and Gas**—The controversy as to the relative merits of these illuminants was renewed last week before the Society of Architects, when Mr. B. R. Tucker, late chief surveyor to the War Office, read a paper on the "Lighting of Buildings, etc., by Electricity and Incandescent Gas." The author prefaced his paper by explaining that its object was to assist in creating an increased interest in this subject, which formed a most important part of an architect's duty. In employing artificial light, it was essential in the first instance to determine the amount that might be required, the mode by which it was to be measured, and the laws that governed its intensity. On a general average, he stated that the amount of light required for reading and writing might be taken as 1 c.p., which sounds a rather moderate estimate; but the lecturer added that the nature and extent of the reflecting surfaces influencing the light were important factors. He prescribed a light of not less than 5 c.p. for work containing a quantity of detail, and this should be doubled for specially fine work, such as engraving. Having remarked upon the necessity of a definite standard of light for comparison, Mr. Tucker described the legal candle standard and dealt with photometry. The author held that the law of inverse squares demonstrated the necessity of a reasonable number of separate lights judiciously separated, instead of a large single light, in order to obtain the highest economy in the illumination of large buildings. As the purpose of lighting was generally to produce a certain intensity at the plane of illumination—usually assumed to be from 3ft. to 4ft. above the floor—the lights should be so located and of such a nature as to produce a minimum illumination of the candle-power at the parts farthest from the source. The best artificial light was that which was soft, steady, well diffused, and approached nearest to the yellowish-white hue of natural light. The author then dealt with the methods of the various types of electric and gas lamps. The former, he said, gave excellent results in such buildings as studios, but lacked the penetrative power of incandescent gas for street-lighting in a fog. Gas did not lack its champions in the discussion which ensued, while electricity found an enthusiastic advocate in Mr. E. T. Ruthven Murray, who eulogised the purity of the light given by the Nernst lamp. As to public lighting, he remarked that some arc lamps were placed too high and others too low. They ought to be about 20ft. from the ground, and then excellent illumination was obtained over the whole street. Regarding enclosed arc lamps, he recommended members desiring to see a model light of this type to inspect those just outside the Central London Railway at the Bank. The exhibitors at the recent Earl's Court Gas Exhibition had paid a high compliment to electricity by making their big lamps resemble arc lamps as far as possible. His experience was that electricity was the more economical illuminant. Mr. Tucker, in replying, said he believed they had not got to the end of incandescent gas lighting, and, on the other hand, the future might witness a great improvement in electric lamps.

**Paralleling a 5,500-kw. Turbo-Alternator.**—The *Electric Club Journal* in its issue of February gives an account of the operation in parallel of the 5,500-kw. 25-cycle Westinghouse turbo-alternator supplied to the Interborough Rapid Transit Company, of New York, and erected in the Seventy-fourth-street power-house. This was the first Westinghouse unit of this size to be put in service, although a number of similar machines are approaching completion. The day after this machine was first put in service it carried loads as high as 8,000 kw., and for considerable periods loads between 7,000 kw. and 8,000 kw. were of common occurrence. This turbo-generator is the largest now in service. Within a few days after the machine was put in service, and while operating in parallel with six of the slow-speed 5,000-kw. machines in the same station, a

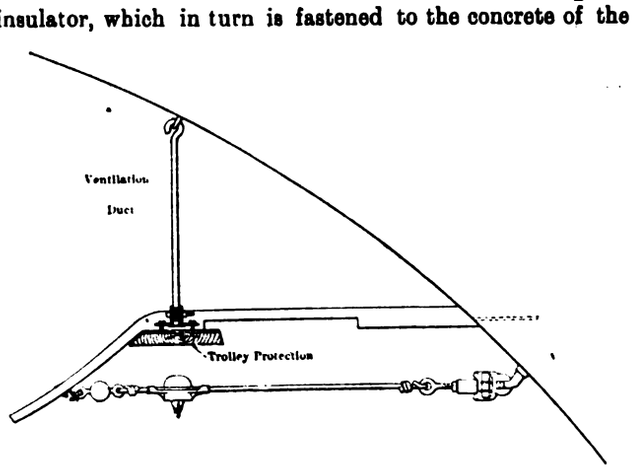
Digitized by Google

short-circuit occurred among the main leads at a point between the turbo-generator and the switchboard. This was a dead short-circuit, and it tripped the automatic switches on all the slow-speed machines, which were set at almost three times full-load current, but did not trip the safety switches on the turbo-generator on account of the fact that the arc was so violent that it burned off the leads to the safety devices for this particular machine, though these leads were in a separate conduit. It was necessary to cut the turbo circuits off by hand and the short-circuit, therefore, continued on this machine some little time before it was cut out. Careful examination of the generator showed that it was absolutely uninjured in any way, as far as could be determined, and was ready for service immediately afterward, but could not be thrown in with the other machines on account of the main leads to the switchboard being burned off. The machine has been in service with heavy loads since these leads were replaced. The 5,500-kw. turbo-generator is run in parallel with the other machines in the station, and the only notable difference in its operation and that of the slow-speed machines is due to the difference in the speed regulations of the two types of engine. The steam-turbine was adjusted so that it regulated much more closely in speed than the low-speed engines, and, in consequence, the turbo-generator takes the fluctuations in load. It is noted that when the turbo-generator is operating in parallel with the slow-speed machines, the latter carry a much steadier load than when the steam-turbine is cut out, the turbine unit appearing to take all the fluctuations when it is in circuit. This unit, therefore, has something of the effect of a flywheel or a storage battery on the system. This effect, if considered undesirable, can be modified readily by adjusting the speed characteristics of the steam-turbine. On account of its uniform rotative velocity and its relatively large flywheel capacity, the turbo-generator is particularly suitable for operating rotary converter systems such as the Interborough Rapid Transit Company's. Some months ago a series of tests was made to determine the paralleling qualities of turbo-generator units. At full voltage the machines ran perfectly in parallel. Fluctuations in speed were so slight that periods from one to fifteen seconds could be obtained for synchronising. When the voltage was reduced to 60 per cent. of the normal, the machines would carry the full current without any evidence of hunting. The voltage was further reduced and tests were made, until about 15 per cent. of the rated voltage was obtained. Under these conditions the machines still remained in parallel when carrying full-load current, but the conditions of paralleling were not perfectly stable, the load being transferred from one machine to the other at an irregular but not rapid rate. As the synchronising power varies approximately as the square of the voltage, it was extremely low in the last test mentioned. It is evident, therefore, that but small interaction is required between such machines to maintain parallel operation.

**The East Boston Tunnel.**—The East Boston Railroad Tunnel, which was recently completed, presents some features of interest. The system, which is about two miles in extent, consists of a single tunnel with double lines. A ventilating duct extends from one of the termini under the harbour to an intermediate station. The duct, which is seen in the first diagram, has a cross-section of about 38 square feet, and it is divided into two portions by a separating wall located midway between the two ends. On each side of the partition there are 14 openings, each 4ft. by 1ft. 5in. in area, in the flat portion of the duct, and at intervals of about 550ft. there are other groups of openings, diminishing in number as they approach the fan chambers, which are located at the discharge ends of the ducts. A cross-section of the tunnel beneath the harbour is shown in the first illustration. Guard rails are laid throughout. There are three sets of conduits, those in the centre carrying power cables belonging to the railway company, while those on the right and left contain the wires of the Edison Electric Lighting Company and the New England Telegraph and Telephone Company respectively. Considerable interest attaches to the arrangement of the guard rail, of which a description is given by the *Street Railway Journal*. There is a flange space of $1\frac{3}{4}$in. between this rail and the service rail, and the top of the



guard rail is $\frac{9}{16}$in. higher than the top of the running rail. The officials of the company consider that this arrangement practically precludes the possibility of derailment. Another advantage is the facility which the arrangement offers for repairing, as either rail may be taken up without putting the other out of service. Fig. 2 illustrates the method of supporting the trolley wire. A strain insulator is anchored into the concrete of the tunnel by an expansion bolt. The stranded steel span wire is attached to the other end of this insulator. It terminates in a globe insulator, which in turn is fastened to the concrete of the



tunnel ventilation duct. The hanger is attached to the span wire supporting the trolley 13ft. 6in. above the top of the rail. The spans are 20ft. apart. Above the trolley is a fireproof guard-strip, designed to keep the trolley and wire away from the concrete. For lighting the tunnel there are three rows of 16 c.p. 110-volt incandescent lamps spaced 12ft. apart. The supply may be drawn from three sources, this arrangement being adopted to render the illumination secure The lamps can also be fed from the trolley circuit. The lighting of the station and tunnel sections is controlled locally instead of from a central switchboard.

## SWITCHGEAR FOR THE FISHER STREET SUB-STATION OF THE METROPOLITAN ELECTRIC SUPPLY COMPANY, LIMITED, LONDON.

This gear was designed to the specifications of Mr. J. S. Highfield, chief engineer to the Metropolitan Electric Electric Supply Company, Limited, who was the originator of several of the unique features herein described, such as the remote control from one platform, the protected extra high-tension connections, the depressor method of starting, etc. The gear was designed in detail, constructed, and erected by the British Thomson-Houston Company, Limited, of Rugby, to whom we are indebted for the following particulars.

The sub-station which the Metropolitan company has erected to take up the load formerly carried by the historic Sardinia-street station, is unique in the amount and variety of switchgear required. The high-tension voltage used by this company is, in a sense, the highest to be found in the United Kingdom. Ten thousand volts on each of the two phases, with one end of each phase earthed, gives over 14,000 volts between the unearthed conductors, and a voltage to earth corresponding to 17,000 volts three-phase with earthed neutral. On the other hand, the direct-current voltage is unusually low, the system of distribution being three-wire with 100-volt lamps, calling for a voltage across the outers at the sub-station varying from 220 to 250 volts.

The complete equipment of this sub-station, including the batteries, will easily be able to take care of a peak load of 25,000 amperes at this voltage. Thus, the input is at an unusually high voltage; the output is an unusually large current, while the number of machines and feeders is also unusual, the station being laid out for an eventual capacity of 10 500-kw. motor-generator sets, three three-wire storage batteries, three balancers, six battery boosters, two starting machines, four extra high-tension lines, and 105 direct-current feeders. To control this equipment there has been installed a main low-tension board (Fig. 1), running the whole length of the station—75ft.—a gallery (Figs. 2 and 3) above the same, filled with instrument panels, rheostats, control handles, etc., and a subway the same length filled with extra high-tension gear; in addition to various incoming line equipments, booster panels, balancer starting gear, a station lighting panel, etc., scattered at various points convenient to the corresponding machines or circuits.

The most striking feature of this switchgear as a whole is the arrangement by which both machines constituting a motor-generator set are handled entirely by remote control equipment from one position. Both the extra high-tension switches feeding the synchronous motors and the corresponding direct-current generator panels are mounted approximately opposite their respective machines, the extra high-tension gear being in the basement and the direct-current panel on the floor immediately above. In the gallery immediately above both the extra high and the direct-current equipments, there is mounted a pedestal with operating handles for all of the switches normally used in handling the set, both alternating-current and direct-current, both types of switches being mechanically controlled from this distance by means of gas-pipe and bell-crank connections, in the same way that extra high-tension oil switches have been controlled in the past; this arrangement being unique in its extension to direct-current apparatus. Against the wall in the gallery, immediately behind the above-mentioned pedestal, is a panel carrying all the instruments, both alternating-current and direct-current, and all small switches—such as field switches—synchronising receptacles, relays, etc., but without any extra high-voltage or heavy current leads whatever upon it, all instruments being fed from current transformers, potential transformers, shunts, etc., suitably placed on the panel or in the cells down below, all of the small leads being brought up to the instrument panel through steel piping. This arrangement gives the attendant complete control of one unit from one point. Under his hand he has the direct-current starting switch, the positive and negative main circuit breaking switches, the extra high-tension oil switches, the generator and motor field rheostat hand-wheels, and the corresponding field discharge switches. In front of him are the direct-current voltmeter and ammeter of the corresponding generator, together with an alternating-current voltmeter and two alternating-current ammeters for the two phases respectively of the synchronous motor. On the same panel are two field ammeters, one for the generator and the other for the motor, as well as the synchronising receptacle, alternating-current relays, switch indicating lamps, etc.

Taking up the switchgear more in detail, the extra high-tension power is received in the two-phase form, 60 cycles, 10,000 volts, as generated in the power-house of the company at Willesden. It enters the Fisher-street sub-station *vid* four transmission lines, two from one other sub-station, and the other two from a third sub-station, which in turn is independently supplied, thus linking these various sub-stations in a ring system with duplicate lines each way around the ring. Each such line consists of two concentric cables, one for the red phase and one for the blue phase. The outers of these concentric cables are earthed at Willesden, and are all of practically earth

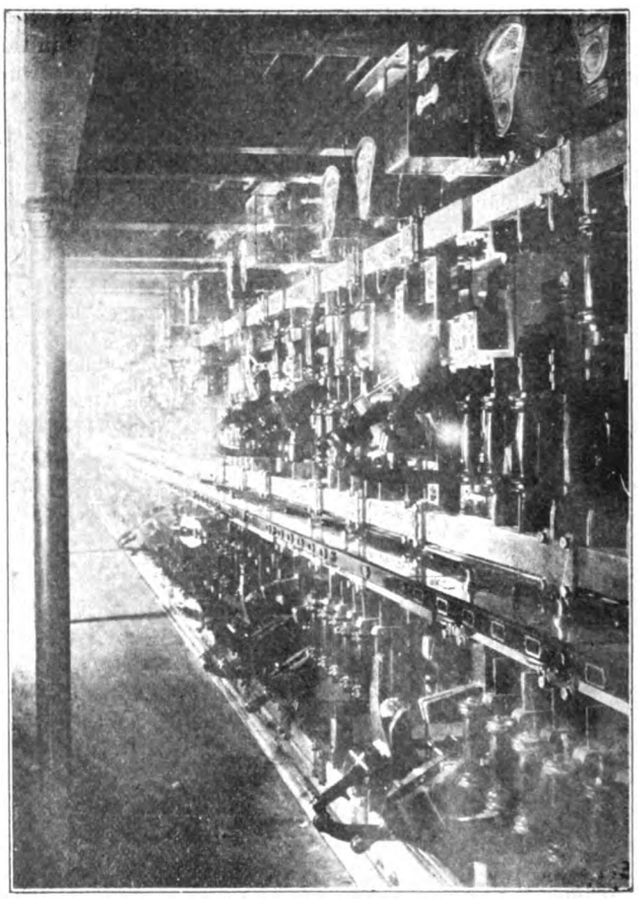

FIG. 1.—View of the Low-Tension Main Switchboard, showing the 'Bus Bars, Switch Fuses, Shelf Barrier, Meters, etc.

potential throughout. They are all, therefore, easily controlled by open-air knife switches of ordinary low-tension types. The inners are, however, controlled by extra high-voltage oil-break switches of the B T.H. single-pole type, one in each phase. These switches are arranged for automatic tripping by means of overload relays energised by current transformers, connected in the outers. Each phase of the incoming lines—*i. e.*, each cable—can be tripped independently of the other. The arrangement of one of these line equipments is shown in Fig. 4.

The extra high-tension gear for the synchronous motors is similar in character—*i e*, it consists of two single-phase oil-break switches in separate masonry cells with knife switches in the outers, these knife switches being mechanically interlocked with the oil switches so that the knife switches cannot be opened when the oil switches are closed or the oil switches closed when the knife switches are open. This is obviously advisable, as otherwise the 10,000-volt circuit could be opened on the outer switches, or a machine could be closed on the inner switches, with the outer switches open, which would give 20,000 volts on the outer

Digitized by Google

as soon as the synchronous motor drifted out of phase. In the case of the machines, the current transformers which operate the overload relays are connected in the inners not pass through the outer cables, or any current transformers connected therein. In this way a certain amount of selective operation is obtained between the

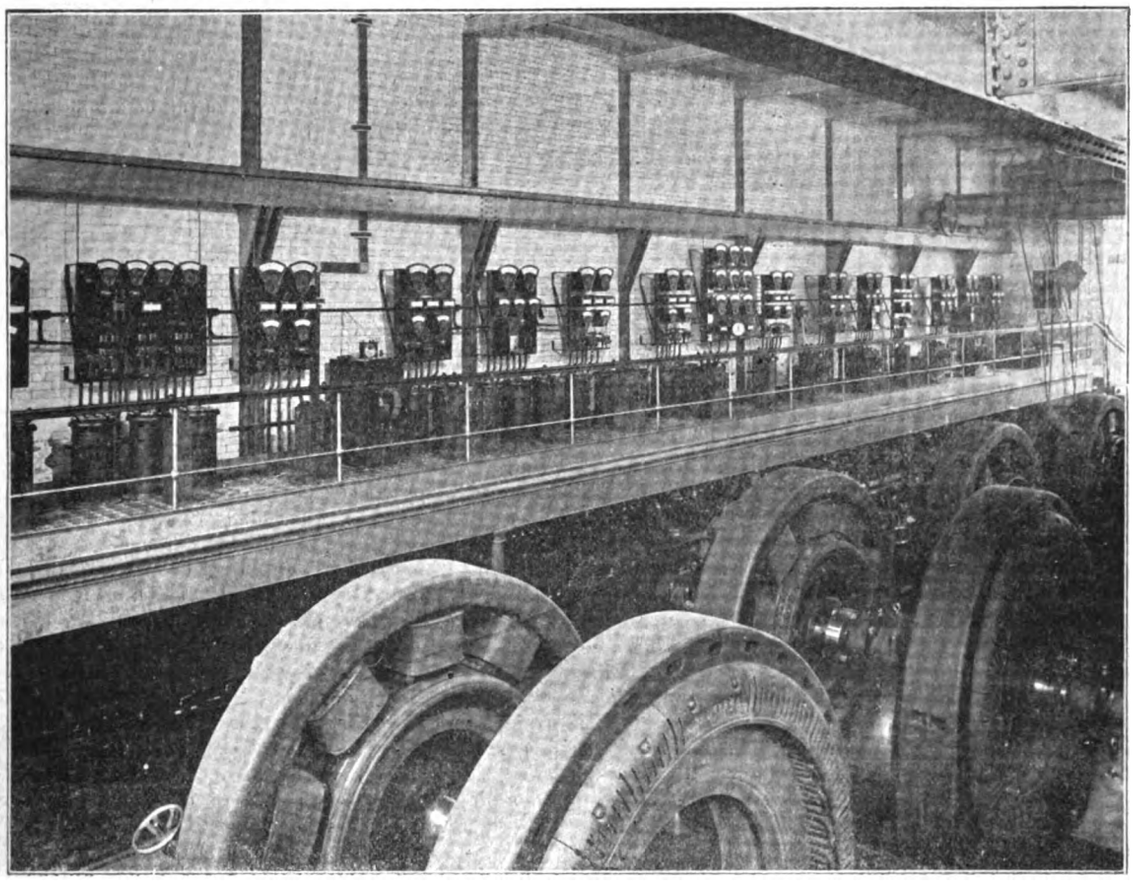

FIG. 2.—General View of the Switchboard Gallery, showing the Main Low-Tension Switchboard beneath same.

between the machine oil switch and the synchronous motor, the idea being that a breakdown of the insulation of the high-tension motor winding to the frame would cause machine oil switches and high-tension feeder oil switches, any machine breakdown tending to operate the corresponding machine switches only, and not to trip out the lines

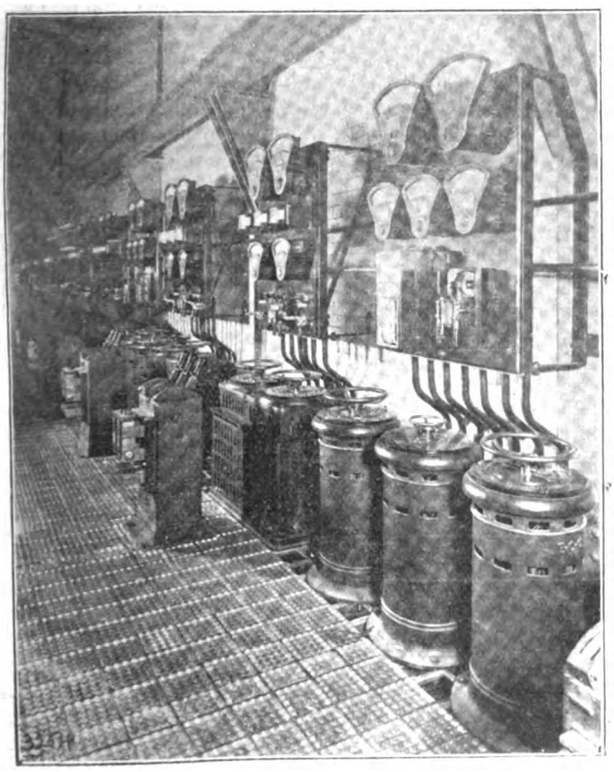

FIG. 3.—View in the Switchboard Gallery, showing a Battery Panel and a set of Balancer and Booster Field Rheostats in the foreground, with Motor-Generator Equipment in the background.

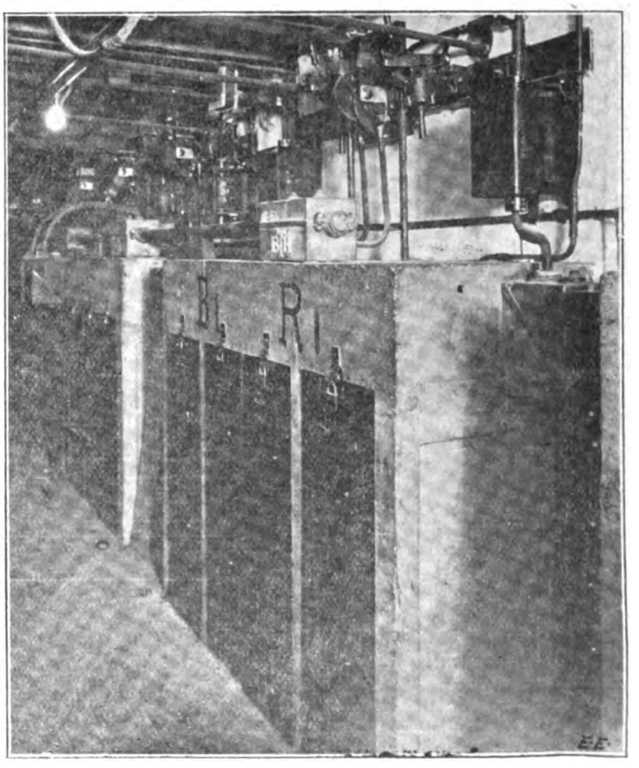

FIG. 4.—Equipment of Oil Switch Cells, Series Transformers, Trip Gear, Outer Knife Switches, and Cable-Dividing Boxes for an Incoming Extra High-Tension Line.

a heavy rush of current from the power station into the said synchronous motor, and thence back to the power station through earth, which current would between the stations, which would only be affected by cable breakdowns between inner and outer conductors.

The machine automatics are so arranged that a fault or

Digitized by Google

overload on either phase opens both oil switches on the two phases, differing in this respect from the incoming line automatics which are independent. Each synchronous motor is equipped with one pilot or potential transformer for synchronising, and for properly adjusting the voltage of the synchronous motor when the machine is run up from the direct-current side. Each of the four transmission lines is equipped with two potential transformers, one on each phase, for the supply of voltmeters on each phase, power-factor indicators, and recording watt-hour meters, designed to measure the total station input. The extra high-tension connections throughout the station are unique for their complete enclosure of all high-tension current-carrying parts. The oil switches are in stone chambers or cells, with steel-plate doors, which are normally locked; but even if these doors are opened, access can only be had to the oil-switch tanks, mechanism, etc., all of which are earthed. Access to the live parts of the switch can only be obtained by removing the switch tank.

The high-tension sub-station 'bus bars are made up of concentric cables, the inner core of which is the only dangerous conductor, the outer core being of practically earth potential, and being insulated and surrounded by the usual lead sheath, which in turn is solidly earthed. For branch lines this concentric lead cable 'bus is tapped into the oil switches in large cast metal cable-dividing T boxes mounted on top of the oil-switch cells, the inner being carried down directly through the bases of these boxes into the oil-switch cells through long corrugated porcelain insulators. The boxes are filled with extra high-tension cable compound. No knife disconnecting switches or links of any kind are provided for isolating the oil switches from the sub-station 'bus bars, but the extra high-tension 'bus is divided by three sets of oil (inner) and knife (outer) switches into four sections, any one of which can be shut down when the other three sections are carrying the load, thus allowing cleaning, repairs, adjustments, alterations, or extensions to be made to any part of the gear, without exposure of the extra high-tension inner conductors in the form of knife disconnecting switches, or in any other form of bare copper. Outside the stone cells for oil switches and potential transformers, every inch of any inner or high-tension conductor is either inside a concentric and lead-covered cable, or is surrounded by a compound filled and earthed cast-metal dividing box.

The only points at which the high-tension inner conductors are at all exposed are the terminals of the glass-tube fuses used to protect the potential transformers. These fuses are mounted on their transformers in masonry cells, with doors normally locked. This enclosure of all extra high-tension parts in cable boxes or switch tanks is somewhat novel, as compared with ordinary three-phase work with non-insulated 'bus bars in compartments, and so extreme as to be at times awkward when it is desired, for example, to apply a short-circuit for testing or machine drying, but it has proved most remarkably safe in combined operation and construction; a large amount of work having been done by men in actual contact with the extra high-tension 'bus bars, considering the cables as such, after the station was in continuous service.

The main direct-current low-tension switchboard on the machine-room floor is made up of black enamelled slate panels, solidly bolted to 3in. by 5in. R.S.J. "H" girders, which are framed into the building, and form supports for the gallery, the latter having been designed to suit the switch-gear. The lower half of this board is devoted to the negative side of the system, and the upper half exclusively to the positive side of the system, the two polarities being isolated by means of a slate shelf extending in front of and behind the main panels, throughout the length of the board. Each polarity is fitted with duplicate 'bus bars, which will be used for running at two voltages. Each of these four 'bus bars is divided into three sections by means of eight 'bus sectionalising switches. The feeder panels are distributed between the generator panels, so that there is no great concentration of current in any one section of the 'bus bars, which are each of six square inch cross-section. Each generator panel is equipped with one Thomson recording wattmeter, one 3,000-ampere ammeter shunt, and in each polarity one double-throw B.T.H. 3,000-ampere laminated brush switch, by means of which the machine can be transferred from one set of 'bus bars to the other, this being normally done when the machine is out of service. Each polarity is also equipped with one B.T.H. 3,000-ampere remote-operated switch of a circuit-breaking type, handled from the gallery above. The switch of this type on the positive polarity is equipped with a reversal relay, which is set for about 600 amperes—*i.e.*, just sufficient to act as an overload relay when the machine is being started from the direct-current side.

The 105 direct-current feeders for which provision has been made at this station, consist of concentric or triple-concentric lead-covered cables, varying from one square inch concentric to ·4 square inch triple-concentric. To allow ample room for safely drawing this lead-covered cable up behind the live board, and for fixing the fittings for carrying the currents into their conductors, the main 'bus bars have been fitted on the front of the board. Each feeder is protected by switch fuses, which are made double-throw, so that the feeder can be fed from either the high or the low 'bus. On each polarity of each feeder there is also an ammeter shunt, two ammeters (one positive and one negative) being provided for each five feeders, with suitable swivel switches so that each ammeter can be connected to any one of five shunts. The outer conductors of the triple-concentric feeders are connected through suitable clamp fittings and screw plugs to a neutral 'bus, which runs along the base of the board near the floor.

In the main switchboard there are also three battery panels, each equipped with double-throw laminated brush switches, by means of which the battery can be connected to either the high or the low 'bus on each polarity. The main control of the battery is, however, accomplished at the booster panels, which are located near the boosters. The neutral 'bus is connected to the centre of the battery, enabling the battery to assist the balance of the system, especially in the case of out-of-balance faults. There are no end-cell switches, all variations of battery voltage being obtained from boosters which are driven by the balancers. Each balancer drives two boosters, one for the positive and one for the negative end of the corresponding battery. Adjacent to each booster is a corresponding booster panel, equipped with three main switches, by means of which the battery can be either connected through the boosters to the 'bus bars, or can be connected directly to the 'bus bars, with the booster entirely kept clear. A small centre-zero voltmeter at the top of the panel indicates the amount and direction of the boost.

Each battery equipment is designed for a load of 4,000 amperes—*i.e.*, four square inches of copper have been put in each lead, and each meter, etc., has been designed for the same current. Each battery is equipped with two Thomson recording wattmeters, with ratchets, which prevent them from running backwards, the connections of one meter being reversed, so that one indicates the total charge while the other indicates the total discharge of the battery. Each battery is also equipped with one curve-drawing main ammeter, one curve-drawing neutral, or out-of-balance, ammeter, and one curve-drawing voltmeter connected directly across the cells. The balancers are connected with fields crossed and with one field rheostat, consisting of a fixed resistance between the fields, with a movable tap from the neutral 'bus bar. Each booster is equipped with a series shunt reversing rheostat with contacts so arranged as to connect the booster field across any desired voltage from 125 volts positive to 125 volts negative.

Provision has been made in the switchgear for automatically cutting off the torque of the booster by opening the booster fields in case the booster should tend to run away on the battery current when the balancers are disconnected from the 'bus bars by blowing of their fuses or any other cause. This provision has been made as it is considered inadvisable to put in any automatic circuit-breaking switches in the battery circuits, the idea being to keep the batteries connected to the bars through all emergencies, unless disconnected by hand. To provide for such disconnection, the booster panels are equipped with brush toggle switches with magnetic blow-out auxiliaries, which are capable of clearing the maximum output of a battery on a short-circuit.

Digitized by Google

Various provisions have been made for starting the motor-generators. As a rule they are started from the direct-current bars through a starting box, with an induction motor-generator set as a reserve in case the direct-current power fails completely. This induction motor-generator set may be connected on the direct-current side to any generator, entirely independently of the main 'bus bars. An addition to the usual starting equipment is a motor-driven booster, or—to use a somewhat more explicit term, which has been applied to this machine—a depressor. This machine consists of a direct-current motor driving a direct-current generator, which can be connected in place of the starting box. In the use of this machine, the depressor is thrown into circuit with a voltage approximately equal to that across the 'bus bars, after which the depressor voltage is gradually lowered, thus bringing up the voltage on the unit to be started. The advantage claimed for this machine is that a unit can be started from rest with about 100 amperes instead of the 400 or 500 amperes usually required when starting through a dead resistance. The starting current runs up as the depressor voltage is lowered, since the depressor returns less of the starting amperes through its motor as the voltage of its depressing end goes down. As the starting current is much more than the accelerating current, the depressor cuts down considerably the maximum demand for starting.

All of the starting gear has been so designed that current for starting can be taken from any section of the 'bus, either high or low, but no one 'bus or section of a 'bus can be paralleled with any other by any accidental manipulation of the starting switches. Similarly, no one machine at standstill can be thrown in parallel with another up to voltage through mistakes in the manipulation of the starting switches.

In addition to the instrument panels described on the operating gallery, there are others for the batteries; also one 'bus-bar voltmeter panel, and one pilot panel, equipped with six voltmeters and suitable voltmeter switches and pilot wires for measuring the voltage at the centres of distribution of the network supplied.

## NEW LOCOMOTIVES ON THE VALTELLINA RAILWAY.

(*Continued from page 158.*)

### Electrical Equipment.

Continuing his description of the new locomotives for the Valtellina Railway in *Elektrische Bahnen u. Betriebe*, Béla Velatin deals next with the method of collecting current from the trolley wires. It is noteworthy that both the collectors and switchgear are actuated throughout by means of compressed air from one position. The accompanying illustration (Fig. 6) is a diagram of the electrical connections, while Fig. 7 shows the arrangement of the pneumatic system.

Each of the new locomotives is fitted with collectors similar to those which have been in use since the service of electric trains was inaugurated. It will doubtless be remembered by many of our readers that we gave a full illustrated description of the type of locomotive originally constructed for the Valtellina Railway in our issues for April 10 and 17, 1903. Hence it will be unnecessary to recapitulate all the details here. Suffice it to say that the locomotive is provided with duplicate collectors, each being supported at either end by a construction (Figs. 8 and 9) having two arms. The axle pole carries two roller contacts of copper, insulated from each other and revolving upon insulated ball bearings. The current is conducted to carbon blocks, fixed at either end of the roller contacts, and thence by means of insulated cable enclosed within the hollow arms into the locomotive. These collectors are used alternately, according to the direction of travel. The arrangement is very different from the sliding bow, which it resembles, however, in appearance. Referring to Figs. 8 and 9, it will be seen that the bases, of which there are four on each locomotive, differ from those of earlier design. Thus the bearing pressure of the contact rollers on the trolley wires is regulated by means of compressed air acting on a piston connected to the tension springs. A glycerine dash-pot serves to buffer the shocks when the device is raised

or lowered. Experience has shown in working the Valtellina line that the collectors give the best results when their bearing pressure is properly adjusted to the speed, and advantage has been taken of this fact in the new design. In other words, means are provided whereby the pressure of the roller contacts on the trolley wires is varied to suit the two dominant speeds for which the locomotives are constructed. The air-cylinder is fitted with a double piston. Compressed air is admitted only to the main piston for the lower speed, but when the master controller lever is put over to full speed air is admitted simultaneously to the auxiliary piston through the hollow piston rod, thereby increasing the tension on the springs, and, at the same time, the bearing pressure of the roller contacts on the trolley wires. This pressure amounts to 6½ kg. for the lower speed and 8½ kg. for the higher. A further improvement consists in that when the collectors are lowered a cut-out in circuit with the leads opens automatically, thus breaking the connection with the locomotive and with the contact rollers. Each base rests upon four high-tension insulators, consisting of cast-iron bells provided with wrought-iron bolts, the latter being insulated from the former by means of stabilit and porcelain.

From the above it follows that two valves are provided for regulating the collectors. One of these valves is operated directly through a lever, by means of which air can be admitted to the main piston or released from the same; the other belongs to the auxiliary piston, but in this case the supply of compressed air is governed by the position of the master controller. The lever which operates the first-mentioned valve is fixed in the driver's cabin at a convenient height. This lever enables the two collectors to be raised and lowered, either independently or together.

The high-tension fuses, lightning arrester, choking coils, and branch circuit boxes are fixed overhead in the driver's cabin. Fig. 10 represents one of the high-tension main fuse boxes into which the current from the collectors is first conducted. Single-pole main fuse boxes of this type are provided on each locomotive. The fuses proper consist of several parallel silver wires embedded in porcelain, and the boxes are locked. The leads from the collectors are connected behind the fuses, the high-tension lightning arrester (Fg. 11) being branched off at the junction point. The two main leads are then taken each through a choking coil to two main branch boxes, from each of which four branches are taken. Two of these branches are in turn connected up to the primary switches, and two through double-pole fuses to the step-down transformers which furnish current to the air-compressors, etc. All high-tension leads are enclosed in metal tubes, which are carefully earthed.

The motor controller and switchgear are actuated through pneumatic controllers, of which there are two provided, one at each end of the locomotive. It may be mentioned here that liquid resistances are employed on two of the new locomotives, and metal ones, experimentally, on the third. Each of the pneumatic or master controllers has

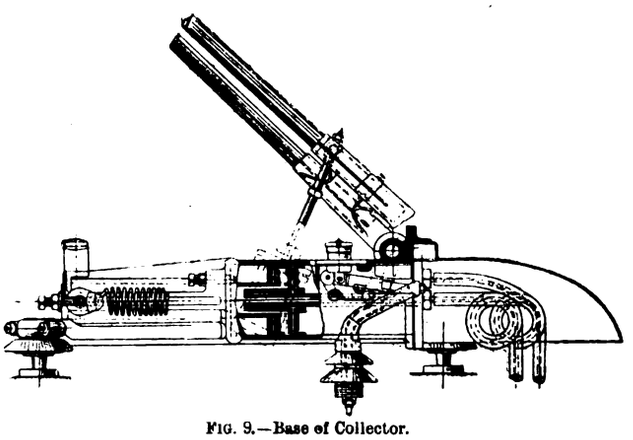

FIG. 9.—Base of Collector.

Digitized by Google

three levers corresponding to different functions. The main lever serves to actuate the starting and regulating valves. In starting up, the driver pulls this lever over to the first position, and so opens the starting valve, admitting compressed air to the main switches and rheostats. This closes the main switches and brings the rheostat switches in position for the next step, without actually closing them. He then moves it forward to the second position, at which the regulating valve is operated and the liquid resistance inserted. Attached to the shaft of the starting lever is an eccentric which, upon the lever being

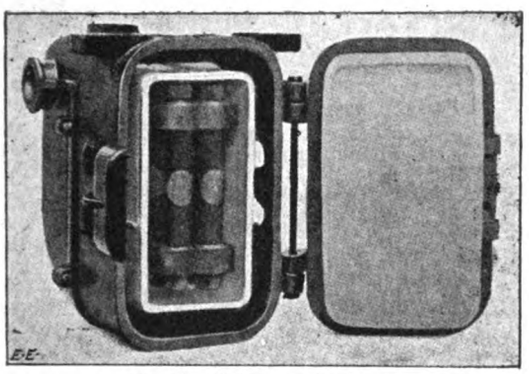

FIG. 10.—High-Tension Fuse Box.

moved further round, compresses a spring which, in its turn, acts upon a diaphragm so as to open a valve through which compressed air is admitted to the corresponding chamber in the top of the rheostat until the accumulated pressure is sufficient to balance the thrust of the spring, thereby causing the diaphragm to return to its original position and the valve to be closed again. In this way a variation in the volume of air admitted to the differential chamber in the top of the rheostat corresponds to an equal variation of the starting current, due to the construction of the rheostat. The further the starting lever is pushed over the greater is the volume of compressed air necessary to force the diaphragm back, and in proportion as

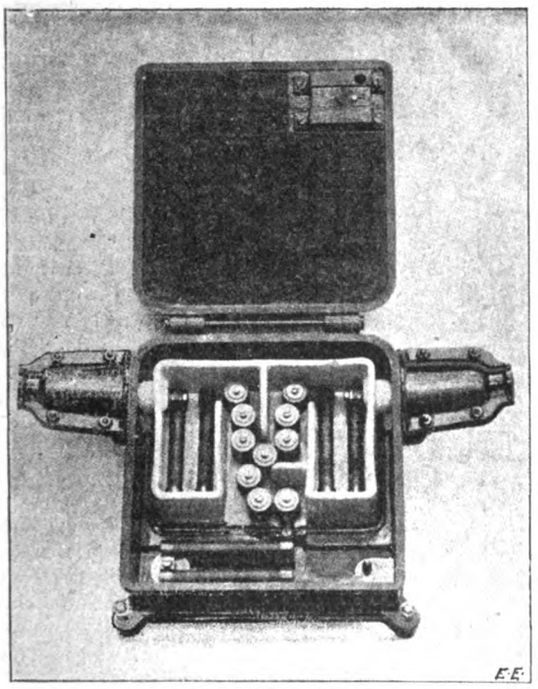

FIG. 11.—Lightning Arrester.

the volume of air admitted to the air-chamber in the top of the rheostat is increased, the greater is the starting current. Each position of the starting lever corresponds, therefore, to a certain constant starting current or tractive effort, which the driver can observe on the ammeter and regulate accordingly. In stopping the sequence is reversed, the return motion of the eccentric causing the diaphragm to be forced by the compressed air behind it in the opposite direction, and a valve to be opened which establishes a connection between the chamber in the top of the rheostat and the atmosphere. The action of setting the lever back to the off position also closes the starting valve, cuts out the water resistance, and opens the primary switches.

The second lever, which is arranged underneath the starting lever, serves to reverse the direction of travel, and operates the corresponding valve. The regulator valve has two ports, which are connected with the corresponding sides of the pistons attached to the main switches. According to the position of the regulator valve, these ports are open either to the compressed-air reservoir or the atmosphere. The third lever is situated on the left of the starting lever, and operates the motor controller. This lever is usually turned inwards when the motors are in cascade. By turning it outwards the motor controller is, through the medium of compressed air, set to the full speed position, only the high-tension motors being then switched in. The speed-regulating valve connected with this lever has, therefore, only two positions: in the one, the pipe to the motor controller is open to the atmosphere, and in the other to the compressed-air reservoir.

The individual levers are so interconnected that the reversing lever and the lever through which the motor controller is operated can only be moved when the starting lever is in the off position, and the main switches, as well as the resistance, consequently cut out. There are two of these pneumatic controllers—one at each end of the locomotive, as already mentioned; and provision is made whereby it is rendered impossible to use both of them simultaneously.

*(To be continued.)*

## AUXILIARY RAILWAY SIGNALLING.

The recent deputation to the Board of Trade has again raised the question of the sufficiency of railway signalling, and particularly that of the auxiliary signalling brought into use to meet conditions not always obtaining. The recent accident at Cudworth on the Midland Railway has also revived interest in the subject for a time. Such revivals are periodical, and coincident with the occurrence of accidents of a sufficiently serious character to attract public attention. Unfortunately, the interest taken is of a superficial and transient character, and is speedily driven from the public mind by other events, and the subject is allowed to lapse until a similar event again stimulates interest. Nothing is done, principally because it is nobody's business to prevent the recurrence of such accidents, and the Board of Trade confines its action to enquiry into the circumstances attending the occurrence and the apportionment of blame, as far as it is possible to do so, for each particular occurrence. It cannot be said at this time of day that there is any novelty in the circumstances attending railway accidents. The arrangements for signalling are such that accidents are mere repetitions, and arise from one or two variations of practically one set of conditions. Under such circumstances the persistent neglect of the lessons taught by successions of accidents seems nearly criminal when looked at from the standpoint of the travelling public, and almost fatuous from that of the railway shareholder. To say nothing of the loss of human life, the mere waste of money involved by such accidents as those at Slough, Cudworth, and numerous other places would seem sufficient to stimulate railway companies to an endeavour to remove the slur that lies upon them, as business men, by the periodical recurrence of disasters of the type of those referred to. In business life an excuse may hold good once, but no more. In such cases as this the possibilities of the present system have been demonstrated times without number, but without stimulating action for the removal of the causes.

If the circumstances attending such accidents are closely examined, it is found that they invariably result from some apparently trivial break in the recognised chain of actions as set forth by official regulations. The rules provided by railway companies for the guidance of their servants are most voluminous, and calculated to provide for every possible emergency of which the official mind can take

Digitized by Google

cognisance, and so long as events take place in the order prescribed, the work is carried on with smoothness and dispatch. Railway servants, however, are but human, and consequently their actions and thoughts are not characterised by the machine-like precision which the official regulations desire to promote. Time after time little irregularities, which taken alone were of no consequence, have synchronised and produced terrible results. Momentary aberrations of memory, lack of decision, and the promptitude of action which comes from it, distraction of attention, and want of concentration upon the work in hand, often arising from monotony and sameness of work, and sudden changes in the conditions obtaining, have all played their parts at various times and places. Much, very much, has been done by railway companies to render travelling safe, and to their credit, be it said, that the greater part, or practically all, has been achieved without compulsion. For some years now, however, but little additional work has been done, although the railway service has greatly changed, and the conditions involved by the higher speeds and greater punctuality now insisted upon are much more onerous. The institution of the block system, including the mechanical interlocking of points and signals, upon an almost universal scale something like 30 years ago, has reduced the chances of accident in this country enormously, and all such occurrences as those now being considered may be classed under one head. Practically all railway collisions in this country of such magnitude as to rivet public attention upon them are of the nature of "following collisions." Double lines of rails prevent the "meeting collisions" which are so common on the single lines in the United States, when failure to "side-track" at the appointed place occurs. The mechanical interlocking of the points and signals automatically prevents "fouling collision," and has probably been the greatest safeguard ever provided in railway working; but, as with all preventatives, the difficulty in properly appraising its value, otherwise than by deduction, is extremely great. "Following collisions," as has already been observed, result from human weaknesses. Where mechanical control is absolute, safety of operation is absolute also. The present system of signalling allows unlimited repetition of action, uncontrolled by actual conditions, and the observance of signals depends entirely on concentration of effort upon one class of indication, and the presence of conditions necessary to the proper fulfilment of that effort. Hence the desirability, and even necessity, for some auxiliary methods of signalling, to supplement that already in use, becomes apparent, since, as already stated, concentration upon the work in hand may be unconsciously relaxed, as in the Slough accident, and the conditions for perfect vision do not always exist, and the changes may come so rapidly, as in the Cudworth accident, as to prevent the ordinary arrangements to meet such changes being carried out in sufficient time. It is not intended in this article to deal with checks upon the signalman to prevent repetition of actions not in consonance with the conditions obtaining, and the rules regulating his actions, but to confine attention to methods for ensuring that signals exhibited for the guidance of the driver are really brought under his notice, whatever the conditions of the weather, however rapidly the changes may occur, or however preoccupied his mind may be with other matters.

Of late years numerous suggestions for auxiliary signalling have been put forward, and the most generally approved are those which aim at giving signals on the engine more or less perfectly in accord with the indications afforded by the ordinary semaphore signals. If the characteristics of the latter signals are carefully considered, estimates of the requirements for complete repetition will be more easily made. Whilst the "distant" and the "home" and "advance" signals have, generally speaking, the same appearance, the character of the former differs from that of the two latter in some respects; and the two first-named differ from the last in others. The "distant" signal when "on" is of a cautionary character only, and may be passed by a train, whilst the "home" and "advance" are absolute "stop" signals, unless supplemented by hand signals. On the other hand, the "distant" signal when "off" gives more information than a "stop" signal, inasmuch as the cycle of interlocking is such as to prevent the "distant" from being lowered until both the "home" and the "advance" connected with it are also lowered. Hence a "distant" signal when "off" indicates that all other signals within that signalling range are also "off," and the road is fully prepared to the next block section ahead. There are, of course, certain limitations to such absolute conclusions, and the various signals ahead of the "distant" must be verified for obvious reasons. These, however, do not affect the argument in any way whatever.

The "distant" signal differs from both the "home" and the "advance" in that the two latter are "position" signals—*i.e.*, they indicate positions on the line which must not be passed by a train when these signals are "on." The "distant," however, is a "position signal" of another kind in that it indicates approach to a range of signals. This, of course, is more of the nature of a "localisation of position" at the time, and is not an indication of a position at which a stop must be made.

At junctions, again, the "distant" and "home" signals possess another characteristic, which the "advance" does not possess, in that they are "route" indicators, and by their positions, relatively to other signals of the same character, they indicate to drivers of trains which of the divergent routes has been prepared for the passage of the train. This, of course, is an "operating advantage," and is not connected with any question of safety. Such an operating advantage is, however, of the greatest importance as regards dispatch of traffic, and is only second to safety in railway working.

Hence the characteristic indications of the semaphore signal are greater than would appear at the first glance, and the information conveyed to the driver is correspondingly fuller under normal conditions of weather. Assuming no other cause of error, accident would only result when the indications are disregarded in consequence of preoccupation, etc., as at Slough, or when the weather conditions are such as to render them invisible, as at Cudworth, Northallerton, etc. Under such conditions the detonator system of fog signalling is brought into use, and it is interesting to trace the character of the indications then provided, and compare them with those obtained under normal conditions. Detonators give a sound indication by explosion when passed over by the engine, when the signal to which it applies is "on." The character of detonator employed is the same for all signals, and each signal is repeated separately and independently. There is, therefore, no difference made for the cautionary "distant" or the stop "home" or "advance." It follows, also, that in no case can a "route" indication be given, and also that when approaching a "stop" signal the "position" indication, which has been referred to as a characteristic of such signals, can only be imperfectly conveyed to the driver, and only effectively if he is travelling so slowly as to enable him to stop at any moment. Hence it is evident that all the explosion of a detonator tells the driver is that *a* signal at danger is being passed by him, and he must rely upon his localisation of his position on the line to enable him to judge the character of the signal he is passing.

One of the questions raised at this point is, "Are the explosive signals sufficient notification for the driver's complete information, supplemented by the localisation of position he is able to bring to bear, and which will include his remembrance of his position in the regular cycle of signalling for each block post?" Another question is, "What is the organisation for bringing the detonator system of auxiliary signalling into use? Is it effective, and such as to meet all the conditions that reasoning and experience show to be probable?" Taking the second question first, it may be pointed out that, to go no further back than the Cudworth accident—although it would be possible to point to other cases—the arrangements were not made sufficiently quickly, and that the prime cause of the accident was due to the auxiliary fogman not reaching his position in time to signal the express in accordance with the indications of the semaphore. The necessity for fog signalling arises at most irregular intervals, and, naturally, railway companies utilise, as far as possible, their ordinary men for this special work. This, of course, involves the withdrawal of the men from their ordinary occupations,

Digitized by Google

which as a rule they are unable to continue under such circumstances; or if the conditions arise after ordinary working hours, their withdrawal from their homes and equipment. This undoubtedly takes some time, and although signalmen during the interval are instructed to put down detonators, this does not seem to have been done. Hence to these two causes, in themselves independently trivial, the accident at Cudworth was due, and, as already stated, this is not an isolated case.

Turning now to the first question propounded, it remains to be considered whether, in emergency signalling, it is necessary to endeavour to arrange for *complete repetition*. Complete repetition necessarily means a *duplicate* system, and if one is sufficient for the most onerous conditions as well as those ordinarily met with, the other system is superfluous. It may be thought that, having obtained a system which fulfils all conditions, it should, and would, replace the less efficient. From an operative point of view this is incontestable, but it rarely happens that this view is the only one, or even the most important. Railways have now been established for a comparatively long period; sufficiently long in any case to allow of the standardisation of their signalling apparatus, and the amount of money sunk in the provision of the existing apparatus is sufficient to preclude the wholesale scrapping so much favoured by some—theoretically and at other people's expense. Whether engineers like it or not, finance has, and always will have, the last word.

Hence in the case of railway signalling, as in all other practical cases, compromise is necessary. In detonator signalling, as already observed, the driver must use his knowledge of his locality, and his position at any moment in the cycle of signalling, to judge of the character of the signal he is approaching and act accordingly. He knows that the first signal he will meet on approaching a block post is the "distant"; if he get a signal, there he knows perfectly what to do. It is often pointed out, however, that the all-right signal is given by the absence of an explosion, accompanied by a hand-lamp signal, which he may not see. With this combination it is sometimes contended that the driver will lose his bearings in the absence of the landmarks with which he is familiar under normal conditions. The driver, however, has other means of judging his position. Every alteration in the configuration of the road "talks" to him, so to speak. The changes of direction due to curves, the passing over or under bridges, the difference between iron and stone bridges, differences in the character of the road-bed, the passing of stations, cabins, etc., running over crossings and switches, all tell their tale to the driver at their own points on the journey. Hence drivers who are well acquainted with the road are in no danger of mistaking their position.

The next point to be considered is the question of route indication, and on this point no information whatever is vouchsafed to the driver. Whilst this is the case, it must be remembered that in this country the movements of most trains are telegraphed from point to point on the route, and the times at which they leave these points are telegraphed forward. Moreover, the block signalling code provides identification signals, so that signalmen know the character of the trains approaching them. Further, trains run at certain fixed times, and even if not punctual to their booked times their positions are known from the telegrams alluded to above, and the times they will pass any point are known. Hence the signalmen at junctions know perfectly well what trains are approaching, and may set the proper route.

Hence, on the whole, putting aside the most important indication of "on," which is given by the explosion, there is little to object to, from the point of view of safety, in the present arrangement. There are, however, certain operating disadvantages. The chief of these is undoubtedly due to the fact that indications are only obtained at *fixed points*. It is true that these points correspond with the positions of the signals for normal conditions, but it must be remembered that such signals under normal conditions of sight are visible to the driver for some distance before they are reached. Hence there is necessity for much greater promptitude of action in responding to the indications during the abnormal conditions considered than under ordinary conditions. This disadvantage is greater when a train passes a "distant" at danger than at other times. In such a case the driver must get his train into control, so that he may be able to draw up at the succeeding "home" signal, *but he will not know whether it is necessary for him to stop there until he arrives* close to it and the detonator explodes. If, during the time he is passing at the slow speed rendered necessary by the considerations given above between the "distant" and the "home," the cause which necessitated the exhibition of the danger indication at the "distant" has been removed, the "home" signal may be "off" when he gets there, and may have been lowered immediately after he has passed the "distant." As stated, he will not become aware of the fact until his arrival at or near the "home" with his train under control so as to stop immediately, if necessary, and much valuable time will be lost, much more, in fact, than is represented by the time which has elapsed between the lowering of the "home" signal and his arrival there.

The above is a serious working disadvantage. Still another disadvantage is the negative character of the "all right" signal, which has already been alluded to. Could these two defects be eliminated, there would, apart from possible breakdown of the organisation for calling out their men, be but little objection to the present method of emergency signalling. But it must be borne in mind that events have shown that disregard of signals has occurred even under normal conditions, and that auxiliary signalling which would be given under more advantageous conditions would compel attention to what, otherwise, would go unheeded.

The application of these remarks lies in the endeavours made from time to time to provide apparatus with a view to repeat on the engine directly the indications being exhibited from time to time by the semaphores under the control of the signalmen. As has already been stated, there is now a very large number of such designs, and it may be of interest to consider, briefly, some of their chief characteristics, to ascertain, if possible, why so little progress has hitherto been made in applying them to practical work.

Such apparatus may be roughly divided into two heads, mechanical and electrical. In one or two cases, however, the systems are partly mechanical and partly electrical; and the purely electrical systems, again, may be classed under separate heads. It is not intended to give any technical description of such systems here, but to confine attention to their working and compare them with the results obtained from the detonator system previously considered.

Consider, then, first the mechanical systems of which Raven's is an example. Here we have an obstruction on the line, working in conjunction with the signal, which is struck by a lever carried under the engine. Operation of the lever opens a special whistle communicating with the air-brake, and the sounding of the whistle gives the indication required when passing a signal at "danger." The obstruction on the line is placed close to the signal repeated, and consequently the indications are given at fixed points in precisely the same way as with the detonator system. The only difference consists in the character of the indication given and the fact that the system requires no special organisation for bringing it into use, as it is always ready. To complete the parallel, it may be observed that the "all right" indication is also of a negative character, and is given by the absence of any effect when passing the signal.

Turning to the electrical systems, there is, of course, a much greater variety in the means of actuation, and, in some cases, a much greater range in the character of the indications repeated on the engine. Some merely give a "danger" signal by the ringing of a bell when passing a given point; others, again, give both "danger" and "all right" signals. Boult's system of signalling—probably one of the most *complete* systems ever invented—aims at giving all the characteristic indications required, and succeeds in doing so. The "Miller" system of signalling directly upon the engine, which was brought into use at Woodhouse Tunnel a year or two ago, is another example of a class of apparatus which aims ultimately to dispense with other forms of signalling. Some of the systems referred to, such

Digitized by Google

as Brierley's and Hoyt's, for example, require mechanical or electrical contact between specially placed apparatus on the line and the engine. Boult's system is independent of contact. The "Miller" system depends upon the operation of circuits upon the engine, when two electrically separate parts of the latter are straddling an insulated point on the track circuit used. In every one of the systems cited it will be seen that signals can only be obtained at fixed points, corresponding to the positions of the semaphores, and so far as the operating advantages, upon which stress has been laid in this article, are concerned, they are in no way superior to the detonator system now in use, and to *this want of the equivalent of the projection of vision*, under normal conditions of operation, is to be ascribed the small progress hitherto made by electrical systems of repetition of signals on engines.

## SURFACE-CONDENSING PLANT DRIVEN BY FYNN REPULSION INDUCTION MOTOR.

In drawing up the designs for the recent extensions at the Burton-upon-Trent Corporation electricity station, it was thought preferable to drive the condensing plant for the new 500-kw. extension set off the alternating-current side of the station instead of the traction continuous side. The Fynn repulsion induction motor, the rights of which are controlled by Messrs. Witting, Eborall, and Co. for Great Britain and the Colonies, was decided on for this purpose, owing to the fact that when starting with a torque equal to that of full load the starting current can be kept down to from three-quarter to full load current. The accompanying illustration (Fig. 1) shows the general arrangement of the plant.

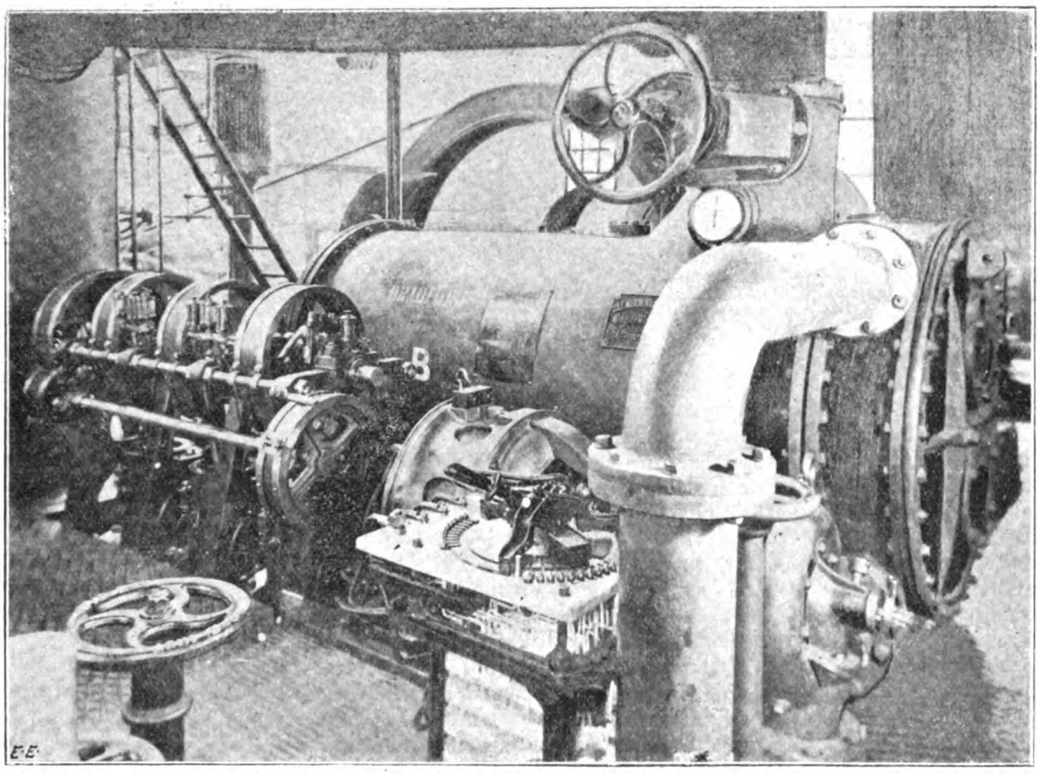

Fig. 1.—Surface Condensing Plant, driven by Fynn Motor, Burton-upon-Trent.

The condensing plant was manufactured by Messrs. Cole, Marchent, and Morley, of Bradford, the motor being supplied through them as well. It consists of the Edwards type of three-throw air-pump and circulating pump by Messrs. Gwynne, the former being driven through gearing by means of a raw-hide spur wheel on the shaft of the motor at a speed of 130 revolutions, and the latter coupled direct to the motor running at a speed of 1,440 revolutions. The air-pump cylinders are 10in. diameter by 10in. stroke, the valves being of the Kinghorn type. The lubrication of all parts is arranged for continuous running. The plant is specified to deal with 13,500lb. of steam with no superheat, and give a vacuum at the condenser of 27in. with circulating water at a temperature of not more than 60deg. F. The plant under test has been found to well fulfil these requirements, and the whole set is a compact arrangement and has dealt with as much as 650 kw. The floor space taken up by the entire set is 14ft. 9ft. by 7ft. 9in., and the condenser stands 4ft. 9in. high above floor level. The large cylinder seen on the extreme left-hand side of the illustration is a grease separator by Messrs. Templer and Ranoe, dealing with the exhaust steam before entering the condenser. The grease and water separated out is automatically discharged, whether the plant is running condensing or to atmosphere, by a Bundy trap.

The motor is of 14 b.h.p., and has an overload capacity of about 40 per cent. On a load of about 15·5 h p for four hours no part of the machine increased in temperature more than 65deg. F. The stator of the motor generally resembles that of an ordinary induction motor, while the rotor is generally similar to the armature of a rotary converter. It has two interconnected windings on it, the free ends of one being connected to slip-rings, while the end of the coils of the other are connected up to a commutator. The operation of starting up the motor is as follows: After closing the main switch putting the current on to the stator windings, the starting switch is put on to the first notch of the resistance in circuit with the brushes on the commutator side of the machine. The motor driving the condensing plant reached a speed on the first notch of 1,060 revolutions in five seconds, which is a performance equal to any continuous-current motor.

There are 13 resistance notches, the speed rising up to full as the switch moves over these. The slip-rings are then short-circuited by pushing in a projecting knob at the spur-wheel end of the motor shaft. The starting switch is then moved back to the first position, and the whole of the brushes bearing on the slip-rings are then raised in one operation by means of a small lever handle. The starting of the motor and carrying out the above operations can be done in 1 to 1¼ minutes. The commutation is absolutely sparkless under all conditions. The starting current is just about full-load current, this being 82 amperes.* The efficiency guaranteed was 83 per cent., but owing to a fairly high power factor being specified, the latter was improved to

* On lower periodicities it becomes easier to reduce the starting current, and this can be kept down to about three-quarters of full-load current with full-load torque.

Digitized by Google

80 per cent. with a very slight reduction in the efficiency. It will also be noted from the curves (Figs. 2 and 3) that the efficiency and power factor are almost constant from 10 h.p. to 18 h.p.

This particular motor is not arranged for reversing, as this is not necessary. If it is undesirable to shift the brushes to reverse the motor, this being generally the case, then a second winding is provided in quadrature position on the stator to the first winding, the two being in series; when it is desired to change the direction of rotation all that is necessary is to change over one of the windings. It will be seen, therefore, that both windings are always operative.

In the larger sizes of Fynn motor, from 50 h.p. upwards, which also includes traction motors, the Fynn method of self-excitation is provided. This is a very important feature, and has the great advantage of enabling the motor to work at all loads with a power factor of 100 per cent., the efficiency only being effected to a very trifling extent. The actual power consumption when the condensing plant has been dealing with approximately 13,500lb. of steam, which is the guaranteed performance of same, was 12·9 kw., at a power factor of 80 per cent. Allowing for the efficiency of the motor, this gives a brake horse-power of 13·8 for driving the whole set. The total length of the circulating pipe, which draws from and delivers to the River Trent, is 308ft., and the maximum height above normal river level is 17ft.

This is the first application of a motor of this description driving a condensing plant, and was the second Fynn motor in operation in this country, the first being a 7-h.p. machine. In noting the performance of the motor from the curves, etc., it should be understood that the periodicity at Burton is 75, which is a comparatively high figure.

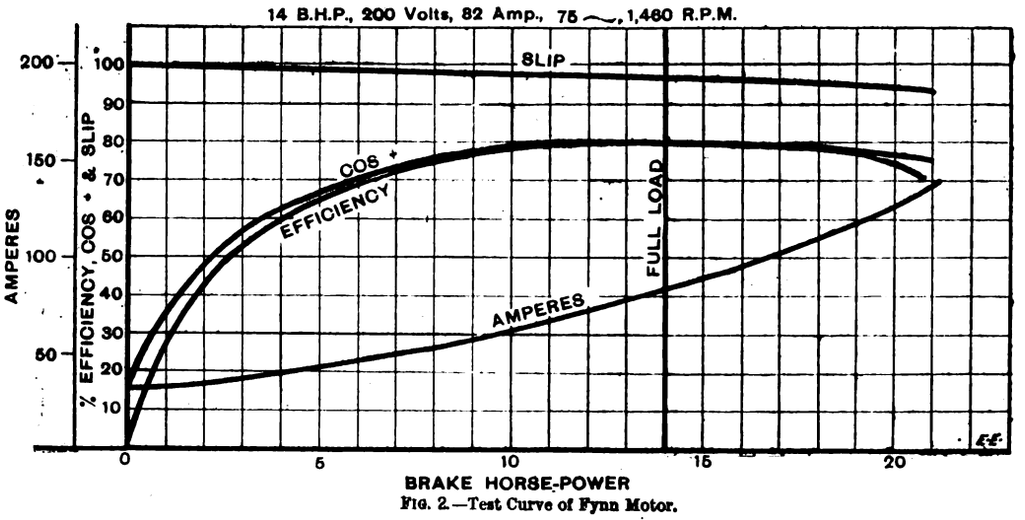

Fig. 2.—Test Curve of Fynn Motor.

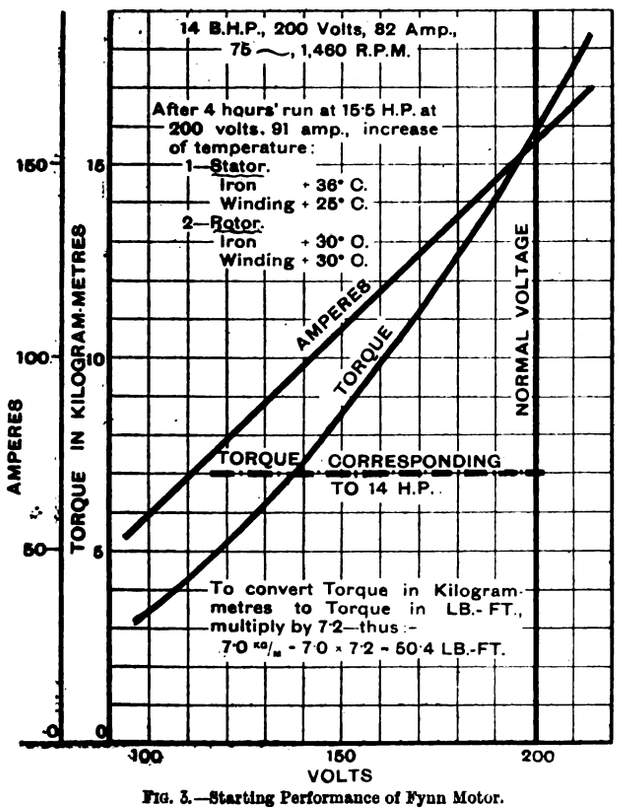

Fig. 3.—Starting Performance of Fynn Motor.

We are indebted to Mr. P. J. Pringle, M.I.E.E, the borough electrical engineer and tramways manager, for the above particulars.

## SOME NOTES ON THE RUNNING OF A PRIVATE LIGHTING AND POWER PLANT.*

BY P. T. BLISSET, ASSOC.MEMB.

In bringing the following notes before you at the request of our local secretary, the object has not been so much to say anything new on the subject of electric driving and lighting as to bring to your notice some points which perhaps deserve more consideration than they have received up to the present at the hands of manufacturers and contractors. Some descriptive notes of a large private three-wire light and power plant may be of interest, in that it shows how electrical driving and lighting has gradually superseded steam driving and gas lighting. The advantages of the extensive use of electricity have long been realised, and the greatest credit is due to those who, in spite of many failures, continued to face the problem of the electrification of factories. It must not be forgotten that the successful application of electricity in works is due more to the firms who experimented on their plants than to the scientists who carried their theories out at the expense of more or less uncomplaining owners, whose prospect of remuneration for their outlay was very remote in the earlier stages of this experimental process.

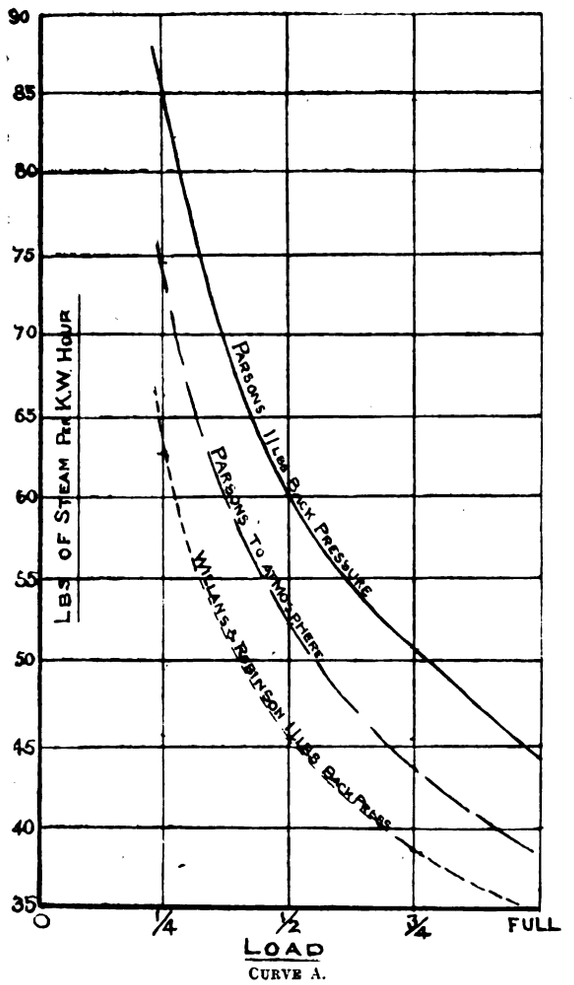
It may be thought that the carrying out the work of successfully driving and lighting a factory electrically would have been a comparatively easy and simple matter, providing that sufficient funds were available. This was found not to be quite the case some years ago. Neither the engineers arranging the plant or the manufacturers supplying it knew exactly what was required, and consequently there was a good deal done that was not altogether satisfactory, and had not some of the advantages to be derived from the use of electricity been essential in the case under consideration—such as cleanliness and its adaptability to isolated units—the plant about to be described would probably never have been installed, as certainly the old steam-driven arrangements were more reliable. It cannot be expected that electricity will be adopted as a general rule until it is as reliable, at least, as steam or gas; and this condition can only be fulfilled by having all details that go towards the making-up of an electrical plant as substantial and as well designed as the perhaps smaller number of details to be found in a steam-driven plant.

Large generating stations and their component parts have been more discussed than the humbler, though none the less important, details of a lighting or small power plant; but it must be remembered that great efficiency in heavy gear is of no value unless the smaller details are also highly efficient, as in the greater number of cases the losses outside the generating station are much greater than those from within. In the

* Paper read before the Dublin Local Section of the Institution of Electrical Engineers, Feb. 9.

Digitized by Google

present instance the problem was the electrical driving and lighting of a large number of steam-driven and gas-lighted plants nearly all working in wet and steamy situations, and

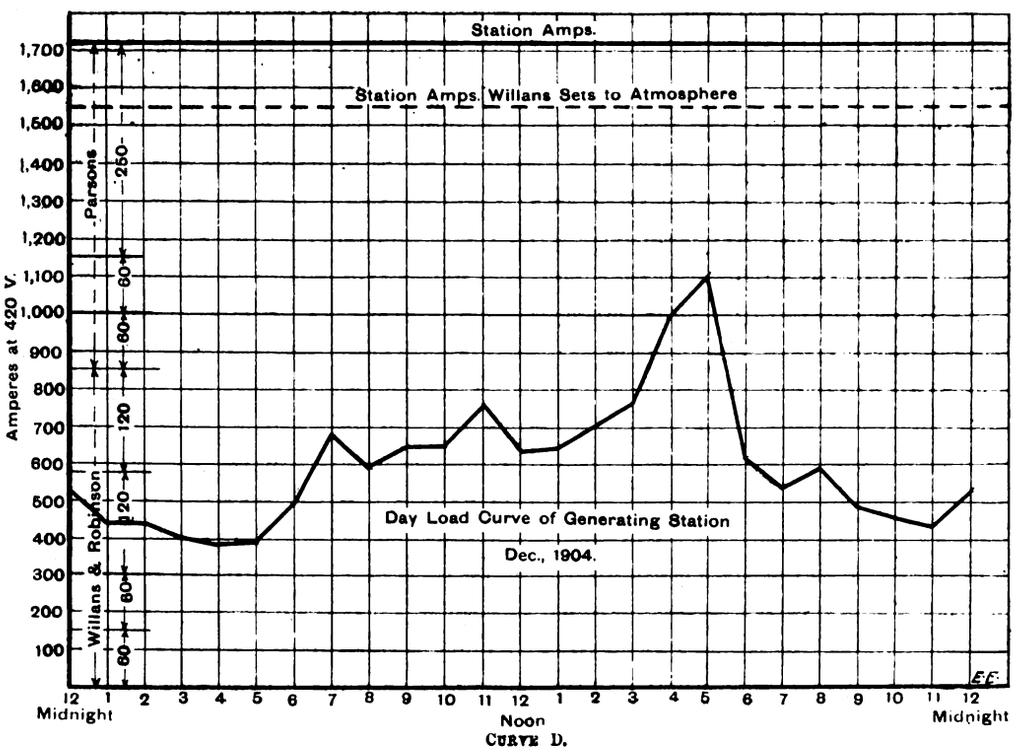


CURVE A.

scattered over an area of about 50 acres. As these conditions were exceedingly adverse to the successful working of the ordinary electrical gear to be obtained 10 years ago, it is very satisfactory to know that most of the original motors and starting gears are still in use and doing good work. The change over from steam and gas to electricity has been going on gradually, the old engines and gas lighting coming in useful as "spares" until sufficient confidence was gained to dispense with their services and depend entirely on electricity. Recently, however, in some large extensions that have been made, electricity is in use exclusively.

A battery of 10 cylindrical multitubular boilers supplies steam to the generating station, each boiler at times generating 72,000lb. of steam at 150lb. pressure per square inch. Induced draught is used, the ingoing air being heated by passing through tubes in the uptake. Sturtevant fans, driven by 11-h.p. or 15-h.p. motors draw the gases from the smokebox, and discharge them through cyclones to take out any dust. These cyclones absorb a large portion of the power of the fan motors, but are necessary, as dust could not be allowed to blow about where there are many open tanks containing water and other liquids. Feed water is pumped by three-throw pumps driven by a 5-h.p. motor through a Royle's heater into each boiler; an injector is also provided as a spare. This range of boilers is fired by three men, and as the load factor of the battery is about 73 per cent., the three men are kept fairly busy. A Vicar's stoker is now being used on one boiler, and gives still better results than firing by hand. The steam is generated at a cost of 12 64d. per 10,000lb., slack coal being used. The generating station at present contains two Willans compound engines coupled to 120-kw. generators, two Willans of 60 kw. each, two old-type Parsons turbo sets of 60 kw. each, and one Parsons turbo of 250 kw. capacity. The large number of small units is accounted for by the gradual growth of the concern. All the generating sets exhaust into a condenser, the atmosphere, or into a main carrying from 10lb. to 15lb. pressure per square inch, the steam being carried round the works and used for heating purposes. As the demand for heating steam varies very considerably, some of the engines are made to exhaust into the condenser, if cooling water is available, or, failing this, into the atmosphere—*i.e.*, when there is more steam going into the back-pressure main than is required. As there is considerable waste at times, due to exhausting into the atmosphere, a new Parsons 250-kw. set is being installed to work at from 10lb. to 15lb. pressure per square inch, exhausting into a separate surface condenser. Under these circumstances, economy of steam is not of the first importance, as the heat wasted by the engines is made use of afterwards.

Willans engines and Parsons turbines are so well known that a description here is not necessary, but as the two types of machines are running in the same station, a comparison between them might be of interest. A curve (A) is shown comparing the test run of the new Parsons 250-kw. set with a test run of a 120-kw. Willans and Mather set. It will be noticed that there is a considerable difference in the steam consumption, the Willans giving a much better result, but losing a little advantage at the smaller loads. In all probability the Parsons set would show a better comparison if both engines were working condensing. A comparison was made from an actual run of both types, extending over several days, and the results are here given in Table B. These tests were very accurately made by taking the strokes of the pumps delivering feed to the boilers, the amount of water delivered per stroke being measured. It will be noticed from the table that there is a marked difference between a test made with the best load for a machine and one made on an actual run, where the load



CURVE D.

Digitized by Google

is constantly changing, the steam consumption at its lowest, when the Willans sets only were working, showing about 50lb. of steam per kilowatt.

TABLE B.—Willans and Robinson *v.* Parsons. Parsons exhausting at 11lb. back pressure, Willans to atmosphere.

| Time. | Steam per electric unit. | Ampere-hours. W. & R. | Ampere-hours. P. | % work done by each type. W. & R. | % work done by each type. P. |

| 10 a.m.-10 a.m.—5th and 6th | 57·2 | 12.420 | 610 | 95·3 | 4·7 |
| 10 a.m.-2 p.m. | 49·5 | 3,070 | — | 100 | — |
| 2 p.m.-6 p.m. 5th and 6th | 58·7 | 2 560 | 610 | 80·8 | 19·2 |
| 6 p.m.-10 a.m. | 59·9 | 6,790 | — | 100 | — |

The kind of load that the engines were dealing with is shown by an ordinary day-load curve of the station (see Curve D), from which it will be noticed that the output varies from about 380 amperes at 420 volts at 4 a.m. to 1,100 amperes at 5 p.m. The units being small, several of them have to be kept running to meet any sudden demands which are made on the station, so that they are working for a large part of the time on a small load. If this table is compared with some results given of the running of the City and South London Electric Railway, in which some similar but larger machines were used, it will be seen that on a test of a 300-kw. set with the same steam pressure 25·5lb. of steam per kilowatt-hour was used, the engine working condensing. Allowing for its working non-condensing, the steam consumption would probably be about 28·2lb. per kilowatt-hour. In comparison with the engine given in the table, it is a little better than the 32·2lb. which would be used working against atmospheric pressures. The coal consumption for the City and South London station—9·95lb. per kilowatt-hour—does not, however, compare well with the 5·9lb. of coal consumed in the table. It is possible that the conditions of working in the two cases may be very different. Still, it is satisfactory to know that, with regard to coal consumption, this small plant can compare very favourably with some of the larger ones. I consider that boilers generating steam at the rate of 8 5lb. per pound of slack coal shows rather a high efficiency. Referring to the curve (A), the Willans engines and Parsons turbos appear to increase their steam consumption per kilowatt very much when working with half or quarter load, being as much as 87lb. per kilowatt (with 11lb. back pressure) for quarter load on the Parsons and 63lb. at quarter load for the Willans, so that it would be economical to run them at as near their full load as possible.

Perhaps the question of actual efficiency of the machines is not so important within the scope of this paper as their running. The Willans engines have proved rather troublesome and require a lot of attention, the maintenance charges coming out very high. They frequently required taking down and putting together again, which would take a fitter and his helper two weeks to do, costing about £5. 10s. per engine. Occasionally knocking in the engines occurs, but on being taken down nothing wrong is discovered, and when put together again work perfectly well. The oil consumption is also rather a large item compared with that of some other types of engines, three-quarters of a pint of cylinder oil being used every eight hours in each of the 120-kw. sets, and every month or so about six or eight gallons of crank-chamber oil on account of water from the cylinders coming down and floating off the crank-chamber oil if not noticed.

The Parsons turbines give very little trouble, in the later type the oil being circulated through the bearings by means of a pump. Considering that the speed of the 250-kw. machine is 3,060 revolutions per minute, the system of floating the bearing is remarkably successful, and a great improvement on the older types, in which the apparatus consisted of a worm on the spindle engaging in a wormwheel with 41 to 1 reduction, which drove the air-pump, the working of which caused a considerable knock at each revolution of the wheel. On one occasion, the blades having become jammed, a coupling between the turbo and generator, consisting only of a 1in. square spigot working in a square hole, was sheared off. The inertia of the quickly-rotating armature is naturally capable of doing far greater damage than this.

With Parsons sets the wear of the commutator is very considerable, due to the great speed, and sparking is almost inevitable due to the changes of the load, although the brushes are adjusted to the load as much as possible. An arrangement is being made in the new machine, however, to make the position of the brushes fixed for all loads. As the sparking is due to the distortion of the field by currents flowing in the armature, this distortion will be prevented by taking the current of the machine round a coil inside the pole-faces, so that the current flowing in it will be in the opposite direction to that in the armature, the current in the coil neutralising the action of the armature on the field.

The generators are all coupled on to the two 'bus bars at 420 volts of a Ferranti low-tension switchboard, this switchboard having been recently installed at the back of an old Mather and Platt board, which it has replaced. It was erected and the change made over from the old to the new switchboard practically without stopping any of the plant. The Mather and Platt board, which was designed about 1879, was rather a dangerous arrangement, the feeders being plugged on to the 'bus bars and the cables at the back crossing each other in a very risky manner. Some of the terminals were very near the supporting frames, and arced across on one occasion, causing the cables at the back to catch fire. To make matters worse, some energetic fireman turned the hose on instead of using the sand buckets provided.

The engines in the station are governed by two types of governors, the Willans having "centrifugal" and the old type of Parsons "solenoid." As the solenoid governors were much more sensitive than the centrifugal, the Parsons machines took up practically all the variation in the load of the station. This caused overloading frequently, and consequently the sensitiveness of the governors had to be reduced by shifting the point of suspension of a spring, which resists a core being drawn into the solenoid part of the governor. A better idea of the arrangement may be gathered from the photo shown. There is no difficulty in running the two types of engines in parallel providing that the governing is of the same type. The governor of the 250-kw. Parsons is of the pendulum type. There is also another one running with it, which acts on a trip gear and closes the stop valve in case of the turbo running away. At first the trip gear came out occasionally, but on becoming better acquainted with the machine this never happens, and it runs on continuously, requiring no overhauling. Perhaps a good thing in the new types would be to have a second oil-pump, so that if one pump fail the lubrication would still go on.

*(To be continued.)*

## FORTHCOMING EVENTS.

SATURDAY, FEB. 25.

**Institution of Electrical Engineers (Students' Section).**—At 2.30 p.m., visit to the Great Northern and City Railway; meet at Moorgate Station. At 3 p.m., visit to G.P.O. Central Telephone Exchange.

MONDAY, FEB. 27.

**Municipal and County Club.**—House dinner.

**Society of Arts.**—At 8 p.m., "Internal-Combustion Engines" (Lecture III.) by Mr. Dugald Clerk.

**Institution of Electrical Engineers (Newcastle Section).**—"Some Effects in Three-Phase Working," by Mr. W. M. Thornton.

TUESDAY, FEB. 28.

**Institution of Civil Engineers.**—At 8 p.m., "Surface-Condensing Plants, and the Value of the Vacuum produced," by Mr. R. W. Allen.

**Institution of Electrical Engineers (Manchester Section).**—At 7.30 p.m., "Mechanical Construction of Steam-Turbines," by Mr. W. J. A. London.

WEDNESDAY, MARCH 1.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m., discussion on "The Gas-Engine *v.* the Electric Motor for Small Workshop Driving."

**Institution of Civil Engineers (Students' Section).**—At 2.30 p.m., visit to the works in progress for the widening and enlargement of Victoria Station.

THURSDAY, MARCH 2.

**Institution of Electrical Engineers.**—At 8 p.m., "Type Setting by Telegraph," by Mr. Donald Murray.

**Chemical Society.**—At 8 p.m., general meeting.

**Rontgen Society.**—At 8.15 p.m., general meeting (provisional).

**Civil and Mechanical Engineers' Society.**—At 8 p.m., "Engineering Expert Evidence," by Mr. J. F. Reade.

FRIDAY, MARCH 3.

**North-East Coast Institution of Engineers and Shipbuilders (Newcastle).**—At 7.30 p.m., special meeting to consider the present Board of Trade Regulations for Certificated Marine Engineers, and to suggest certain modifications.

**Royal Institution.**—At 9 p.m., "Recent Advances in Wireless Telegraphy," by the Chevalier G. Marconi.

**Institution of Electrical Engineers (Leeds Section).**—Annual dinner.

**Junior Institution of Engineers.**—At 8 p.m., "Possible Improvements in Locomotive Practice," by Mr. W. Longland.

---

**Faraday House.**—On Monday, March 6, Prof. C. A. Carus-Wilson will commence a special course of lectures to the senior students of this institution on "Direct-Current Motor Construction."

**Institution of Civil Engineers.**—On March 22, at 7 p.m., annual dinner at Merchant Taylors' Hall. Sir Guilford Molesworth, president, in the chair.

(Post Free, Payable in Advance.)

*Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to* C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

## TILLING v. DICK, KERR, AND CO.

The decision in this case, unless reversed on appeal, which is extremely doubtful, will have a far-reaching effect. During conversion from horse to electrically-driven systems it has been customary to carry on the work and, as far as possible, continue the service at the same time. The reason for this is perfectly clear and comprehensible. Wherever a tram system has been in operation for some years, be it successful or the opposite, a certain number of people have made business and other arrangements, the due carrying out of which depend upon the tram service. Men select the houses they live in after considering the train and tram services, and have, so to speak, a vested interest in the continued services. The sudden stoppage of a service places them under great difficulties, and the continued stoppage may disarrange their plans altogether, and be the cause of great expense. Hence the slightest consideration of such matters will show how careful an authority or a company is not to interfere with the convenience of its regular customers, and what great pains are taken to keep the service going satisfactorily. The question under consideration has nothing to do with the policy of tramways. For our present purpose we can assume there is no dispute as to their necessity or as to the necessity for conversion. Seeing that these are the ordinary business opinions which must necessarily arise whenever changes in traction take place, it is quite natural to find that the London County Council, when it decided to convert the southern tramways to electricity, held that it was necessary as far as possible to continue the service. As the judge in this case said: "The special Acts of the London Tramways Company and the General Tramways Act provide that the uppermost surface of the rail shall be on a level with the surface of the street, and that the rights of the public to pass over or along the streets shall not be abridged save as in the Acts provided. For the purpose of effecting the conversion of the South London system of tramways, the London County Council made a contract with the defendants, dated Dec. 31, 1902, by which the latter undertook the work described therein, and in a specification annexed, at a certain price. The specification provided, amongst other things, that the contract should include the provision and maintenance of all temporary lines, turn-outs, and cross-over roads to be used during reconstruction, so as to interfere as little as possible with the tramway traffic. The contract and specification also contained provisions casting upon the defendants the duty of observing the provisions of the statutes, and the responsibility for all damage caused by interference with traffic or otherwise. Clause 13 of the specification particularly provided for the continuance of the tramway traffic." It will be seen from these remarks that in their tender the contractors had to consider the things specified, and had also to consider the continuance of the tramway traffic, and whether such continuance in the manner which they adopted would be legal or illegal. We need not labour the question now, for there can be no two opinions in the matter that the methods adopted to continue the traffic necessarily interfered with other traffic using the roads, and interfered detrimentally. It seems from the judge's observations that this interference, necessary for the continuance of the traffic, was at the contractor's risk, as the contractor was responsible for all damage caused by interference with traffic or otherwise. Our object is the moral of all this, and not with the facts. Messrs. Tilling have obtained the legal decision that they are entitled to the relief they ask—which is to recover damages for the accidents caused by the obstructions placed

Digitized by Google

on the ordinary road surface by the contractors. What these damages will be, has to be considered—but this is the moral. After this a contractor who undertakes to carry out the conversion of tramways in large towns will know that he is under obligation to pay damages to all and sundry that can prove that they have been in any way damaged by the obstructions used to carry on the ordinary traffic. Unless this decision is reversed on appeal, Messrs. Tilling have set a ball rolling to which there can be no end. Take one of their points, the strain upon the vehicles, or rather the extra strain upon the vehicles, in being hauled over this obstruction. The number of vehicles that any one firm possesses is comparatively small when the total number of vehicles passing along one crowded street of London or any other large town is considered. The owners of each of these vehicles are at liberty to enter an action to obtain damages, and, as we say, if this decision is supported, they must obtain damages. Such damages, although they may in the first instance have to be borne by the contractors, naturally will not be so in the future. If the undertakers insist that the ordinary traffic is to be continued, and the continuance of this traffic necessitates the placing of turn-outs, or cross-overs, or any other impediments in the track of the ordinary, the contractors, in their tender, will undoubtedly put on an extra sum so as to ensure their having a sufficient amount at the end of the job to pay all of their legitimate expenses and to give them the usual profit balance. In a word, the cost, large as it is now, will be increased by this decision, and there seems to be no way out of the difficulty, for it would not be right, if the property of a third person was damaged to any extent, that he should not obtain reparation.

"One man's word is no man's word,
Justice needs that both be heard."

### TELEPHONE PURCHASE.

SIR,—Perusal of the agreement for telephone purchase proposed by the Post Office reveals many things. Especially is indicated the great need which exists for calm enquiry and caution. A question which naturally rises in one's mind is, "What is the nation going to gain?" The answer may be obvious to the Post Office but not to the outsider, even if he, like myself, is not altogether unacquainted with practical telephony. This agreement provides for the purchase on tramway terms of the company's plant, or such part of it as the Post Office may require, in 1911; but the Select Committee of 1898 said in their report: "The Post Office is under no obligation to buy even the plant of the company in 1911, and the Post Office alone could find a use for such plant should all licenses alike be terminated in that year." So it seems that the Post Office is making a special agreement six years in advance to buy something in respect to which it already possesses what is practically an absolute right to take or reject in 1911. Such a proceeding can scarcely be reckoned a benefit to the nation; and after it, what remains? Simply the right of inter-communication between various insignificant country exchanges of the Post Office, which have never been and never can be of any great consequence; the abolition of terminal fees between these same insignificant country exchanges and those of the National Telephone Company; a right, on paper, couched in words which have proved absolutely ineffective for their purpose in the past, to prevent the company giving preferences as between subscriber and subscriber; a right to prescribe the plant to be used by the company (although the company invariably gives a better service than the Post Office wherever they come into competition, so that the inferior is here assuming power to dictate to the superior). The first two advantages, owing to the smallness of the Post Office exchanges affected, may be described as capable of only microscopic good or evil. The third is something which the Post Office has already power to do in all competitive centres under the Act of 1899, but has found itself powerless to enforce; and the last is a very doubtless benefit, as tending to stereotype plant indefinitely, and so restrict invention, progress, and the introduction of improvements. It may also be described as a device for ensuring the placing of practically all orders for future telephone plant in America.

On the other hand, the company's prospective gains are enormous: (1) It preserves the right to maintain its present high rates in non-competitive centres till 1911, and the agreement sayeth not what is to happen thereafter, although the country's unhappy position with regard to trunk lines renders a reasonable forecast easy. (2) It is given a complete monopoly, apart from the present competing centres, until 1911, because it is quite clear that it is not intended to issue any more competing licenses. The right to do so is preserved in words, but a study of the text shows that in no case is it intended to exercise it. (3) It is left with a practically free hand to fight—and, if possible, crush—the existing competing municipalities by charging unremunerative rates and giving preferences. (4) It secures the right to use streets for underground wires without the permission of the local authority, since the Post Office undertakes to lay underground pipes and cables for the company wherever it may want them. Thus the Glasgow and Brighton Corporations, which have always refused the use of their streets to the company, will be obliged to surrender a right hitherto tenaciously retained, and which will certainly be used to compete unfairly with their own undertakings. And this in spite of the fact that Parliament has hitherto most jealously preserved the right of local authorities to control their own streets, except in the case of unreasonable obstruction to Post Office requirements. It is difficult not to conclude that one of the chief aims of the agreement is to place the competing municipalities at the greatest possible disadvantage as compared with the company. It should be remembered that the corporations undertook telephone work at the express invitation of the present Parliament, which gave effect to a strong report from one of its own Select Committees. But the Post Office rises superior to Parliament, and now determines that the corporations are to be discouraged and discriminated against. While stipulating for free inter-communication, and equalisation of rates where it itself competes with the company, and abolition of terminal fees in respect of its own few insignificant country exchanges, it expressly—Clause 9 (3) (*c*)—denies these benefits to the existing municipal exchanges, the subscribers of which number more than ten times all the country subscribers possessed by the Post Office. Are not municipal telephone subscribers British subjects and entitled to equal consideration with those of the Post Office? From the municipalities have come the only effective opposition which the company has ever known—that of the Post Office it can, and always could, afford to laugh at and disregard—and the company in this agreement has apparently insisted upon the municipalities being burdened with disadvantages which will render the company's hard task in fighting them as easy as possible. The design of the Select Committee of 1898 was that the municipalities should rescue the Post Office from the effect of its previous bad bargains with the company, and that municipal competition should render the acquisition in 1911 easier for the nation; the Post Office now appears to be wishful of getting rid of the necessity of ultimately purchasing the municipal systems by making it easy for the company to ruin them. The Post Office likewise agree to pay for goodwill in those centres where the company's license has been prolonged beyond 1911. But this prolongation was given on condition that the company shall not give any favours or preferences whatsoever as between subscribers. It is notorious that this condition has not been adhered to, so that, instead of undertaking to pay extra in these cases, the prolongation ought to be cancelled.

The clause that provides that the agreement becomes binding, if not disapproved by Parliament before Aug. 31 next, opens up certain curious possibilities. If a dissolution and general election should occur, and the new Parliament

Digitized by Google

is not able to reach the matter by Aug. 31, the company will get this monumental agreement confirmed without the sanction of Parliament.

It is to be hoped that a Select Committee will sit and take evidence without delay. In addition to safeguarding the municipalities, which I regard as absolutely indispensable and a matter of common justice, future telephone users ought to be protected by defining what rates they are to be charged after 1911, a subject which has been very carefully left out of view altogether, although its importance is paramount, for unless the British telephone-using public is to get substantial advantages there is no call to buy the telephones at all.—Yours, etc.,

A. R. BENNETT.

## ALUMINIUM.

SIR,—On p. 129 of your issue for Jan. 27 last, we have that for equal conductivity the diameter of copper is to the diameter of aluminium as 1 : 1·3. Also "for equal insulation to leakage, as the leakage area is greater, the insulating material must also be thicker in a like ratio." This would appear to be sufficiently explicit.

$$\therefore \frac{\text{Insulation on Cu}}{\text{Insulation on Al}} \propto \frac{1}{1{\cdot}69}.$$

The point is that the quantity of insulating medium required varied as the square of the diameter of the conductor.

The word "thickness" in my last letter should be "quantity," as is evident from the context.—Yours, etc.,

WILLIAM SMITH.

## THE GENERAL ELECTRIC.

The fifteenth annual dinner of the General Electric Company was held at the Trocadero on Saturday evening last. There are too few functions of this kind which we attend without some misgivings as to the pleasure of the evening, but the General Electric's annual function is not one. The evening is recognised as unique, and attention is paid as much to detail to ensure the comfort and the pleasure of the guests as is paid by the firm in the organisation of their immense business. It has been said that in this world nothing succeeds like success, and we must say that this applies particularly to all that concerns the General Electric. Its business has been and is a success, and its entertainments are as great a success as its business.

Four hundred gentlemen sat down to dinner in the Empire Room at the Trocadero, and such as are conversant with Messrs. Lyons' catering will know that, so far as meat and drink was concerned, everything was of the best. While, however, excellent food for the body was provided, there was, at the same time, an excellent food for the mind in the references made by various speakers upon questions which concerned the successful carrying out of a large business. Mr. Max Byng occupied the chair in the absence of his brother (Mr. Gustave Byng), who has been abroad on account of his health, and only that day returned to England. We are glad, however, to say that Mr. Gustave Byng has returned better in health. After the toast of "The King and Queen and the Rest of the Royal Family," the Chairman gave the toast of "The Staff," which he considered *the* toast of the evening.

Most of our readers know somewhat of the rapid expansion of this company, but few, perhaps, realise that it employs some 4,500 workmen and workwomen, and some 1,100 persons which may be called the clerical and managing staff, paying some £300,000 in salaries and wages during the year. Such figures give rise for thought. A wages bill which amounts to practically £1,000 for every working day necessitates and points to an enormous output. Mr. Byng, in the course of his speech, preached a model sermon on the text "Detail," insisting that the success of the business depended upon the constant attention given by every member of the staff to details. Nothing was to be overlooked, nothing shirked; every single detail was to be thoroughly examined and thrashed out, so that work might be carried out in their operations in the most economical manner possible. Mr. Byng paid the highest possible compliment to the staff, testifying to their assiduity and loyalty. The toast was responded to by Messrs. Brooking and Dumas, the latter of whom referred to the expansion in the class of work carried out at Witton. They were dealing with gradually increasing units, and at the time of speaking had under test two machines of 1,000 kw. each. Then we had speeches by Mr. Hirst, by Mr. Gaine, Mr. Bevis, Mr. Medhurst, each exceptionally good—far, indeed, above the ordinary run of after-dinner speeches—appealing both to business and to patriotic instincts. During and previous to the dinner excellent music was discoursed by the band, and various entertainers appeared during the evening, meeting with enthusiastic applause. Altogether the evening was a conspicuous success, and if we had any suggestions to make it would be for every person who reads these lines to qualify for an invitation to these annual festivals, feeling assured that he would feel that the success of these evenings proved unmistakably that the success of the General Electric in all its business is amply warranted.

## THE TELEPHONE QUESTION.

The Postmaster-General laid on the table of the House of Commons on the 16th inst. a memorandum embodying an agreement, dated the 2nd inst., between the Postmaster-General and the National Telephone Company, Limited.

The memorandum recites in the first place the agreement entered into on Nov. 18, 1901, by the Postmaster-General with the National Telephone Company for the purchase of the plant of the company in the London exchange area on the termination of the company's license on Dec. 31, 1911. The plant was to be purchased at its value *in situ*, and no payment was to be made in respect of compulsory purchase, goodwill, or past or future profits; in other words, the purchase was to be made on what are known as "tramway terms." The agreement also provided for inter-communication between the systems of the Postmaster-General and of the company in London during the continuance of the company's license, and for uniformity of rates.

The agreement was in effect approved by the House of Commons, after full discussion, on Jan. 27, 1902.

The document proceeds as follows: An agreement, on similar lines, has now been made in relation to the whole country. On Dec. 31, 1911, the Postmaster-General will take over the whole business carried on up to that date by the company, and will acquire the plant of the company on "tramway terms." No payment will be made in respect of goodwill or profits except in the case of the private-wire business of the company (which can be carried on without the Postmaster-General's license), and in the very few cases where the company's license has, under the provisions of the Telegraph Act, 1899, been extended beyond 1911. At the option of the Government, three-fourths, and, with the consent of the company, the whole, of the purchase money may be paid by way of annuity for a term not exceeding 20 years.

Certain powers of objecting to plant as unsuitable for purchase are reserved to the Postmaster-General, and rules for the construction of plant are laid down.

During the continuance of their license the company are to allow inter-communication without additional charge between the systems of the Postmaster-General and of the company. The company will be precluded from showing favour or preference as between subscribers, and the rates charged by the company will be confined within certain limits. If, on complaint and after full enquiry, it is proved that the company is giving an inefficient service in any district, the Postmaster-General may take over the company's business in that district at once without any payment for goodwill.

Certain provisions of the London agreement which are not of general application remain in force. In other respects the provisions of that agreement have been assimilated to those applicable to the rest of the country.

The memorandum concludes by stating that the agreement will become binding when confirmed by the House of Commons, or on Aug. 31, if not disapproved by Parliament before that date.

## THE LAW OF ELECTRICAL DISCHARGES THROUGH AIR.*

The results of some interesting tests on the length of discharge path in air at high voltages are given by H Grob in a recent article in the *Elektrotechnische Zeitschrift*. He points out that the Maschinenfabrik Oerlikon have for many years been building artificially-ventilated transformers for extra high tensions, including some for a working voltage of 36,000 volts and a test voltage to earth of 55,000 volts. When applying the test voltages occasional breakdowns were found to occur, in which the length of air-gap jumped across largely exceeded that given by many of the accepted rules. In order to investigate these occurrences more closely, the writer carried out the following series of experiments.

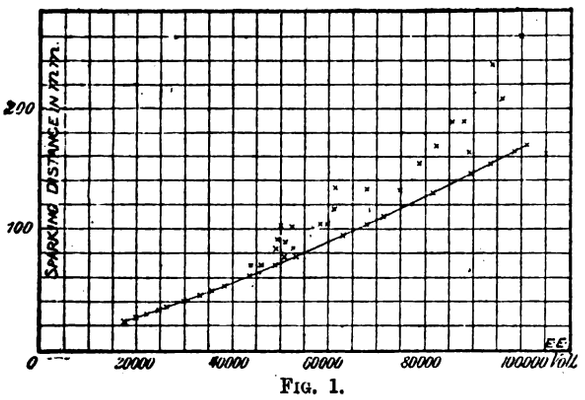

FIG. 1.

Previous experience had shown that the form of the electrodes had a great effect on the results. A smaller radius of electrode, however, by no means always corresponded to a greater sparking distance. In order to avoid change of form, the first experiments were carried out with needle points, new needles being inserted after each discharge. One of the holders was fixed, whilst the other could slide along a groove with scale attached. This needle was gradually moved towards the other until the spark passed. The test voltage was supplied by a generator having a wave of pure sine form, and it was measured by means of a hot-wire voltmeter, so that the values stated below are all effective values. Regulation was effected by means of the generator exciting current, and not by inserting resistances into the main circuit. Up to a voltage of

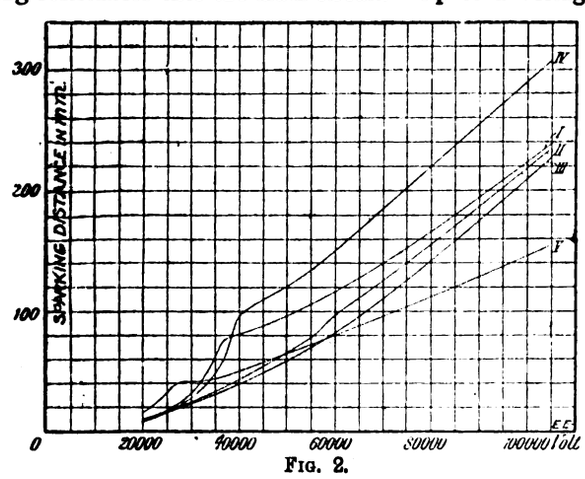

FIG. 2.

about 45,000 the points formed a very satisfactory curve (Fig. 1), but beyond that an unknown influence asserted itself, and entirely upset the results, so that in place of a regular curve a mass of indefinite points was obtained. The lowest points, however, formed an exact continuation of the regular part of the curve. The writer found great difficulty in accounting for this behaviour. Differences in the electrodes could not be the cause, as these would have shown up equally at the lower voltages. Further experiments also negatived the assumption that variations in the quantity of ozone in the air could be the cause.

* Translation from *Elektrotechnische Zeitschrift*, Nov. 11, 1904.

Finally, the needle points were set aside and were replaced by steel spheres of 10mm. diameter. These lead to the absolutely definite curve shown at I. in Fig. 2. This curve showed well what the writer had often previously noticed—viz., that at some point in an otherwise perfectly regular curve a peculiar buckle occurred. He, therefore, determined to investigate this point more closely. On one occasion a series of readings had to be temporarily interrupted to allow a small change in the supply leads to be made. On attempting to continue the experiment, it was found that, with the same spheres and at the same voltage, the sparking distance had unaccountably increased some 40 per cent. The previous arrangement of the conductors was then replaced, and it was found that quite a small variation in the arrangement of the leads sufficed to produce a variation of as much as 50 per cent. in the sparking distance. Further change of the leads in the same sense was found to cause the sparking distance, first, to increase and pass through a maximum and then to diminish and pass through a minimum point. This pointed to the presence of a capacity effect. In order to further test this effect, a pair of metal circular discs of about 10cm diameter were fitted to the supports of the electrode spheres, and arranged to be movable towards or away from one another. It was then found that by suitably adjusting the distance between the discs, the peculiar buckle in the curve could be displaced and diminished (Curve II. in Fig. 2), and could, even within the range of the experiment (20,000 volts to 105,000 volts), be entirely obliterated (see Curve III., Fig. 2). For this last result the discs had to be set several centimetres behind the spheres. There seems, therefore, to be little doubt that a species of resonance is set up in these cases, and this is confirmed by the following experiments, which also show the possibility of other electrical vibrations being present.

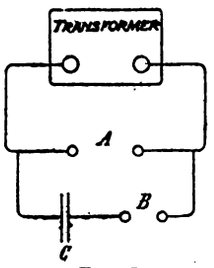

FIG. 3.

The sparking distance can be decidedly influenced by the presence of secondary spark-gaps. In one experiment the arrangement shown in Fig. 3 was employed. A second circuit, consisting of a capacity, C, and a smaller spark-gap, B, was connected in parallel with the main spark-gap, A. The capacity was composed of a sheet of ebonite, having an area of about one square metre and about 10mm. thick, coated on both sides with tinfoil. After each discharge the shunt-gap, B, was slightly increased, whilst the voltage was kept constant. As the distance between the spheres, B (between which a continuous powerful discharge occurred), was increased the discharges at the main gap, A, were influenced in such a way that the distance between these spheres (A) had to be alternately increased and decreased some 10 per cent. as the gap B continuously increased. These results were not absolutely uniform, for at distances of from 1cm. to 3cm. maxima would occur again. Suddenly, with a distance of from 85mm. to 88mm, a new phenomenon was noticed—viz, that the spark-gap at A, for a constant voltage of 60,000, had to be altered from 118mm. to 170mm. when the gap B was altered by an extremely small amount, such as $\frac{1}{100}$mm. It was hardly necessary to touch the micrometer screw carrying one at the B spheres in order to change the sparking distance at A completely. Obviously this indicated the occurrence of accentuated resonance at this point, whilst the previous subordinate maxima were affected by other superposed actions, all varying periodically with the length of the gap at B. The experiment was continued by adjusting the micrometer screw at B once for all so as to give the maximum possible length of spark at A at 60,000 volts, and then taking the complete curve connecting sparking distance at A with the applied voltage, as in the first

Digitized by Google

described experiment. This curve showed that the summit of a buckle occurred just at the previously determined value of 60,000 volts. The result of a further experiment is shown by Curve IV. in Fig. 2. Here the main gap was formed by the same spheres as before, but in series with this two quite small additional gaps of about $\frac{1}{2}$mm. each were inserted. It will be seen that this small alteration considerably increased the sparking distance.

A consideration of these various results leads to a simple explanation of the irregularity of the points in Fig. 1. Although the needles were taken from the same packet they differed slightly in length. Since the distance was always measured between the points, it follows that the distance between the needle clamps varied slightly from reading to reading, and as the end surface of these clamps was by no means negligible this variation in distance altered the capacity of the circuit in an irregular manner, and lead to the results found. It further follows that no curve of sparking distances can be of regular form, for there are always two variables present: the distance between the electrodes and the capacity of the system. On this account curves taken with electrodes of different shape may easily cross one another, as is shown by Curve V. in Fig. 2, which represents the results obtained with electrodes formed of two horn-shaped pieces of 12mm. diameter copper wire.

A comparison of the curve for needle points with that for spheres shows that the sparking distances with the former are less than with the latter, in contradiction of the commonly accepted rule that pointed electrodes increase the sparking distance. If the comparatively small values of Curve V. are also taken into account, it would seem probable that the shape of the electrodes is of quite minor importance compared with their capacity and the self-induction of the circuit. It is remarkable that, in spite of this fact, the curves, at least for the higher voltages, and excluding points of resonance, show a close agreement with the well-known equation: $V = a + (b \times d)$, where V is the breakdown voltage, $d$ is the length of gap, and $a$ and $b$ are constants. This equation, of course, represents a straight line, and it will be seen that the upper parts of all the curves are practically straight. It would be interesting to know whether other observers have noticed the occurrence of resonance as described above.

## SOUTH AUSTRALIAN TRAMWAYS.

The Government last December gave notice to the tramway companies of intention to purchase the whole of the tramways and undertakings authorised as follows—viz, Adelaide and Suburban Tramways Act, 1876; Adelaide, Unley, and Mitcham Tramways Act, 1877; Adelaide and Hindmarsh Tramways Act, 1877; Adelaide and Hindmarsh Tramways Extension Act, 1881; Adelaide and Parkside South Tramway Act, 1881; Adelaide and Goodwood Tramway Act, 1881; Adelaide and Suburban Tramways Extension Act, 1881; Adelaide and Hyde Park Tramways Act, 1882; Adelaide and Suburban Tramways Extension Act, 1882; Prospect, Nailsworth, and Enfield Tramway Act, 1882; Adelaide, Payneham, and Paradise Tramways Act, 1882; Adelaide and Parkside Tramway Extension Act, 1883; General Tramways Act, 1884; Adelaide, Unley, and Mitcham Tramways Act, 1877, Amendment and Tramways Enlargement Act, 1891; Adelaide and Parkside Tramway Enlargement Act, 1896; Adelaide Payneham, and Paradise Tramways Act, 1892, Amendment and Tramways Extension Act, 1889. In accordance with the Act, of which we give extracts below, the Government asked the tramway companies at what price they would sell the undertakings to them. There being little probability of any arrangement being arrived at by mutual agreement, the Government have now invited the companies to appoint one arbitrator to act for the whole of the companies.

Our readers will be interested in the following provisions of the current Tramways Act, 1904, as they are an important consideration to any person tendering to effect the conversion of the lines into a system of electric traction under the conditions contained in the same. The tramways in question are comparatively very old, and little or nothing has been done in late years for their improvement, because the private companies knew that under the Act the Government was bound to buy them out. The tracks in Adelaide are laid at the sides of the streets, the up line on one side and the down line on the other. These will be entirely useless, and will have to be taken up, and it is an acknowledged fact that the conversion will cost as large a sum as the installation of an entirely new system. There is also a feeling in the town in favour of motor 'buses, but apart from the principle of dispossessment of vested interests, which would not for a moment be permitted in the colony, the Government are bound by the Act to purchase.

The Tramways Electric Traction Act, 1904, was assented to on Nov. 24 of that year, and Section 7 (1) states the Government may at any time, after one month's notice in writing to the company of its intention so to do, purchase the whole of the tramways and undertakings referred to in the Acts mentioned in the first schedule at a price to be determined, in default of agreement, as hereinafter mentioned, provided that such notice be given within two years from the date when this Act shall come into force. Section 3 provides that failing agreement in writing as to price within one month after the expiry of the said notice, one arbitrator shall be appointed by the Government and one by the company, and all matters relating to such purchase shall be submitted to the decision of such arbitrators, and such arbitrators shall state the value of the movable plant of such tramways and undertakings. Power is also given to apply to a judge of the Supreme Court to settle the principle upon which the purchase money is to be estimated. It is further laid down that the Government shall not carry out the purchase unless within 12 months after such awards or any agreement in writing as to price entered into between the Government and the company a tender shall have been accepted under Section 10, and that the Government shall grant a lease of the tramways and undertakings as acquired to the person who shall tender for the shortest term in consideration of such person agreeing to effect the conversion of the system of horse traction of the tramways and undertakings so acquired into a system of electric traction. Section 10 provides that each tender shall state the number of years' lease of the tramways and undertakings required by the tenderer in consideration of effecting the conversion and constructing the works specified in the conditions of tender and in plans and specifications to be prepared by the Government. Also that the tenderer shall purchase, at the same price as that paid by the Government, all the tramways and undertakings bought by them; and that the work of conversion shall commence within six months from the date of acceptance of tender, and as regards the tramways mentioned in the second schedule shall be completed as to 20 miles of tramways within one year from such date, and as to the remaining portions of such last-mentioned tramways within two years from such date.

The second schedule contains the following portions of the tramways constructed under the Acts mentioned in the first schedule—that is to say, all the tramways between their present termini in the city of Adelaide and (*a*) the corner of Barton-terrace and O'Connell-street in North Adelaide; (*b*) the terminus of the Walkerville tramway; (*c*) the Payneham tramsheds; (*d*) the Maylands tramsheds; (*e*) the Kensington terminus; (*f*) the Parkside tramsheds; (*g*) the cross roads between Unley and Mitcham; (*h*) the Henley Beach terminus.

The Government is specially empowered with reference to all tramways which they purchase to convert the system of horse traction into a system of electric traction, with or without overhead trolleys, etc., and the following details are laid down with regard to the manner of construction: (1) the tramways shall be constructed and maintained with two rails, the running surface of which shall be laid not less than 4ft. 8in. apart; (2) the uppermost surface of every rail shall be and be maintained on a level with the surface of the road; (3) the rails shall be of iron or steel, and shall weigh not less than 90lb. to the yard; (4) the rails shall be grooved, and the groove shall not exceed $1\frac{1}{4}$in. in width; (5) the rails shall be suitably and properly bonded, and the return circuit shall be of such a character as to comply

Digitized by Google

with the regulations of the British Board of Trade, and the whole of the work shall be carried out to the satisfaction of the South Australian Railways Commissioner. Other clauses refer to the protection of the Submarine Cable Company's cables to the city, 1d. fares, etc.

A copy of the Act may be inspected at the offices of the Agent-General for South Australia, 1, Crosby-square, London, E C.

## INSTITUTION OF ELECTRICAL ENGINEERS.

We give the following points from the resumed discussion on Messrs. Booth and Kershaw's paper entitled "Fuel Economy in Steam Power Plants."

**Mr. Druitt Halpin**, continuing his remarks, intimated that he was favourably disposed towards the controllable superheater, but feared that the complication of joints and the deposit of lime in the pipes, if the water were not properly purified, formed objections to it. Regarding steam production he agreed with the authors, but thought much higher furnace temperatures than those stated by the authors were possible.

**Mr. J. H. Rosenthal**, said that, unlike Colonel Crompton, he could see nothing mysterious in thermal storage; the results obtained at Kensington only demonstrated what seemed theoretically possible. He did not consider specially-trained men necessary for fuel, water, or gas analyses. Twenty-five years' experience had convinced him that mechanical stoking was the only remedy for smoke. More trouble resulted from excess of air with hand firing than with mechanical stokers, which were now provided with devices ensuring the production of from 10 to 25 per cent. of $CO_2$. He dissented from the author's view that there was no thermo-dynamic gain from superheat. At Hampstead the minimum saving of fuel through superheat was 10 per cent.

**Mr. H. N. Holland** agreed with the preceding speaker, that experts were not needed for fuel and water analyses. Regarding the use of express boilers, these required special firing, and he considered that ordinary water-tube boilers were sufficient for general purposes. Air leakage through the brick setting of water-tube boilers was attributable to the great heat produced. His company had tried building up the firebrick line apart from the outer brickwork, and although the lining did not last so long it greatly facilitated repairs. He recommended a second brickwork shell round the boiler, so as to provide an efficient air insulation. His company had found chain grates quite smokeless, and it was sufficient to clean them weekly. The Mersey Railway Company, who used the Roney stoker, were constantly being prosecuted for smoke nuisance. He concurred with the authors as to the value of the Ados recorder.

**Mr. L. Gaster** remarked that the authors had omitted to deal with the advantages of liquid fuel.

**Mr. W. M. Mordey** stated that as the result of his investigations into heat radiation losses he had ascertained that the radiation loss on a transformer case, at a temperature of 40deg. F., was equal to one watt per three square inches.

**Mr. W. H. Molesworth** adverted to the fact that the authors did not deal with the use of pulverised coal, which he had found by tests yielded a material gain in efficiency.

**Mr. W. C. Thomson** contended that smoke could not be prevented when starting or taking off large banks of boilers, even if chain-grate stokers were used.

**Mr. Ruthven Murray**, dealing with one of the points mentioned by the authors, remarked that engineers could not afford to experiment when putting down new plant. In regard to glazed brick casing for boilers, this entailed an extra cost of 12 per cent. as compared with ordinary brickwork, but it prevented leakage to a large extent, and also gave good heat insulation. His experience had been that chain-grate stokers did not prevent smoke.

**Mr. Booth**, in his reply, said that Colonel Crompton was incorrect in implying that the authors had "come round" to the water-tube boiler; it was rather the reverse. He had never been opposed to the water-tube boiler, though he disagreed with the form it took when the Babcock and Wilcox boiler was introduced into this country some 20 years ago. Regarding mechanical stokers, he declared, after extensive experience of them, that they did prevent smoke. He certainly did not deprecate the use of batteries, which had great possibilities; he had simply pointed out some defects in the present method of construction. Regarding superheating, he remarked that the controllable superheater gave a much steadier and a higher mean temperature, as extreme fluctuations were practically damped out by the water control. Having regard to the hour, Mr. Booth intimated that he would communicate the remainder of his reply in writing.

## GLASGOW LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

Prior to the reading of Mr. Lackie's paper on "Earthing" at the monthly meeting of this section held on Tuesday week, the discussion on Mr. Maxwell's paper on "Street Arc Lighting" was continued. We published an abstract of this paper in our issue for Jan. 20 last, together with a report of the discussion which followed it immediately.

**Mr. W. A. Chamen** (Glasgow), in the course of a lengthy communication, said that while it might often be most convenient to stagger arc lamps, he did not think it the best way of lighting a street. Some of the best street-lighting he had seen was in Berlin, where the lamps were suspended along the middle of the road. He was of opinion that for lighting the by-streets of a city laid out in chessboard fashion, lamps either erected on pillars standing in the middle of the road at the points of intersection, and at a considerable height above the ground, or on long overhanging brackets from one of the corners would give a most excellent result. He did not think that lowering gear should be passed by as useless, although perhaps no very satisfactory lowering gear had so far been devised. He did not agree with Mr. Maxwell's separate feeder arrangement, as, however convenient it might be, it was not practicable within reasonable bounds of cost in a large city. Neither did he agree that the only other alternatives—viz., time switches or remote-control switches—were both unsatisfactory. He was experimenting with both time and remote-control switches, and had good grounds for hoping for success in one direction or the other, if not in both. With regard to price charged for current, it was no secret that in Glasgow the current consumed for arc lighting was charged at 1d., which, however, did not include all wages, interest, sinking fund, and depreciation. He considered that 1d. per unit was a fair price in the case of Glasgow for a supply with nearly 50 per cent. load factor, particularly when it was remembered that the total quantity consumed per annum was 1,460,780 units, that there were no meters registered, that there were no bad debts, and no cost of collection of revenue. Mr. Maxwell had said that a negative carbon dropped through the holder was sufficient to cause an earth. That doubtless arose from the fact that the globe rod was attached directly to the pillar in the form of carrier used in most cases where the lamp was fixed directly above the top of the pillar. In hanging lamps, however, that particular mishap could never occur. It was only to be expected that they should come into sharp conflict with their friends the gas engineers over the matter of street-lighting. Gas engineers had said a few years ago that street-lighting was a very poor business, but now they fought inch by inch the progress of street arc lighting. Mr. Wilson had repeated the usual argument that the arc lamp gave intense illumination within a certain area, but left patches of darkness in between. It was worth noting that though the patchy nature of arc lighting was complained of by Mr. Wilson, they found gas engineers doing all in their power to introduce lamps of high candle-power, as, for instance, in Whitehall, London, and in the new thoroughfare between the Strand and Holborn. Mr. Wilson had referred to Brighton, but it should be remembered that in that town flat-flame gas-burners were replaced in by-streets by ordinary incandescent electric lamps before the incandescent gas mantle fairy had cast her magic spell upon so many moths. The main streets and promenade of Brighton were lighted by arc lamps, and splendidly lighted, too. There was the old argument about fog. He did not see that the gas mantle could pierce a fog any better than an arc lamp. If they lived in perpetual fog, flaming coal fires or Lucigen or Wells oil lights would be the only things to do much good.

**Mr. W. T. Calderwood** (Glasgow)—*communicated*: Mr. Maxwell's arrangement for switching in arc lamps from the station from independent 'bus bars and feeders, using separate machines from the ordinary supply till the lamps are lit up, then paralleling in, is rather impracticable for large towns with extensive street-lighting systems. Time switches controlled from the station is, I think, the ideal arrangement. The time switches must, of course, be thoroughly reliable, not too expensive, and give a sufficient time interval between the switching in of the various arc lamp circuits to minimise flickering at the general consumers' lamps. A time switch for this work is being tried in Glasgow arc lamp street-lighting operated as follows: The time switches are placed one into the base of lamp-post of the first of each circuit of 10 arc lamps. In the station there is an arc lighting board containing two small tumbler switches, one open-reading ammeter, and two incandescent lamps. By closing one of these tumbler switches the first time switch in the street is closed, thus lighting up the first 10 lamps. The closing of the time switch operates a time element, which after a predetermined interval closes the next time switch, thus lighting the second circuit of 10 lamps, and so on. On the station board the ammeter is graduated 1, 2, 3, etc., to show the number of time switches that have been closed, and on the last switch being closed one of the incandescent lamps lights up, thus showing that all the circuits have been completed. In switching out the arc lamps all the switches must be opened before the other incandescent lamp lights up, so that the station engineer can tell how matters stand outside, both for switching in and out. The difficulty about arcing at the switches has been got over. The time switches, or arc starters, as they are called, are operated from the station through a three-core $^3/_{20}$ cable, and this cable is dead unless at the time of switching in or out of the lamps. By using arc starters there is a large saving in men's time, and also in current.

**Mr. McWhirter** (Glasgow) said he regretted that Mr. Maxwell had not put before them any figures relative to the use of enclosed arc lamps for street-lighting. He was assured that in America open arcs were rapidly being displaced in favour of lamps of the enclosed type. The circuits were arranged with constant current up to 100 lamps in series, and as the average life of a pair of carbons was over 80 hours, much saving must result; and as no steadying resistance coils were required, the efficiency of the whole system must be high. These lamps were mostly lowered to the ground for trimming, and that also saved labour. He had paid special attention to the gas lighting in the neighbourhood of the place of meeting after Mr. Wilson's eloquent praises of the superiority of the incandescent gas mantle, and it was almost impossible for any form of light to make a worse display. Ten out of 50 lamps were not giving their normal candle-power. About 30 of the mantles were broken, and the remainder were blackened up.

**Mr. Maxwell's** reply was mostly devoted to a vigorous criticism of Mr. Wilson's remarks.

## TRADE NOTICES AND NOVELTIES.

### Kramos Resistance Pieces.

The accompanying illustration (Fig. 1) is a full-size representation of a convenient type of resistance piece manufactured by Messrs. Kramos, Limited, Locksbrook Engineering Works, Bath. We understand that the resistance material is an electro-ceramic product, quite original in its composition, structure, and method of production. At the same time, it is claimed to be infusible, non-inductive, and incorrodible. The piece may be described as a compressed cylinder, covered with mica, and further protected at each end by a non-metallic cap, from which protrudes a brass bolt, these bolts forming the terminals for connecting up the pieces. Each piece can be made with any resistance between 0·5 ohm and 300 ohms. They are all of one standard size, thus a 300-ohm piece is no larger than a 0·5-ohm piece. The radiating surface being the same for all, it is clear that they can all carry the same load in watts. Thus an eight-ohm piece will carry seven amperes for the same time as an 80-ohm piece will carry 2·2 amperes. It is pointed out that "Kramos" resistance pieces are especially suitable for heavy intermittent loads, since each piece will carry only 40 watts continuously, while it will convert an electrical horse-power into heat if the load is applied for a few seconds only at a time, with intervals of rest to allow the heat to be radiated. Combinations of the pieces can be made up for different kinds of loads. An example is shown in Fig. 2 herewith, while others suitable for arc lamp circuits, searchlights, meter testing, controller rheostats, motor starters, and a further variety of similar applications readily suggest themselves.

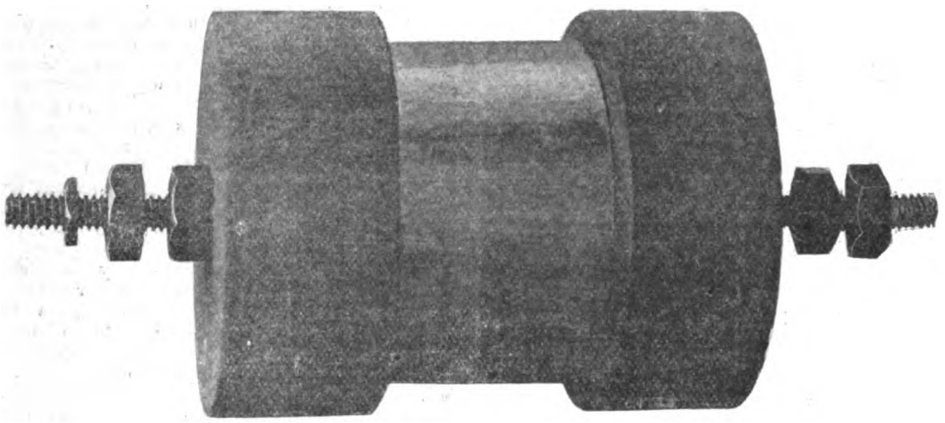

FIG. 1.—Kramos Resistance Piece.

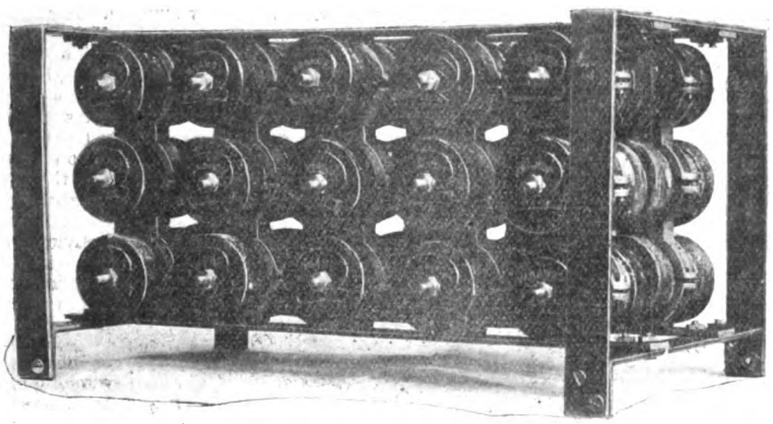

FIG. 2.—Combination of Kramos Resistance Pieces.

### Single-Phase Motors.

In our issue for Jan. 27 last we gave some particulars of a single-phase alternating-current motor which is now being manufactured by the Rhodes Electrical Manufacturing Company at their Bradford works. Through the courtesy of the above firm, we are now able to illustrate this motor. The machine, we are told, embodies all the latest improvements, and, it may be repeated, is a combination of a repulsion and induction motor, being designed in such a way that the operation is, to all intents and purposes, as good as that of a direct-current series motor. It runs at constant speed with the induction side cut in, and is reversible through the medium of an ordinary chopper-type switch. In our previous notice of this new departure we mentioned a 5-b.h.p. six-pole motor of the type in question, wound to operate on a 50-cycle circuit. On test this motor showed an efficiency of 82 per cent., and a power factor of 81 per cent. The same machine, we are told, will start 2½ times its full load running torque comfortably with a starting current not exceeding about double full load value, and will attain its rated speed in a smooth and gradual manner.

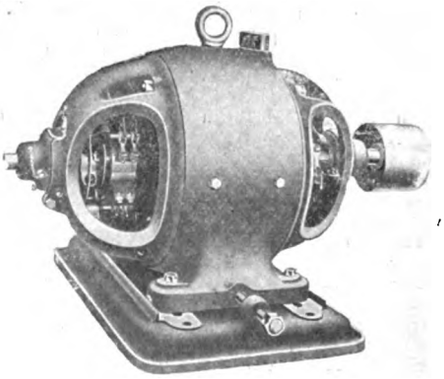

FIG. 1.—A Rhodes Single-Phase Motor.

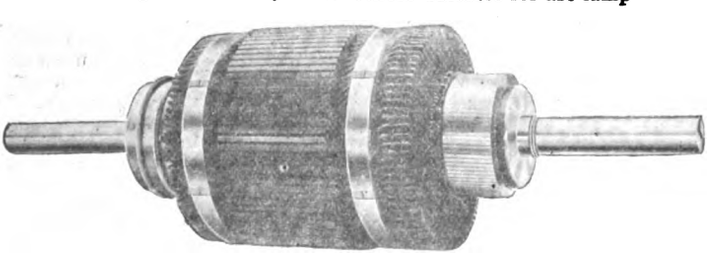

FIG. 2.—Rotor of Single-Phase Motor.

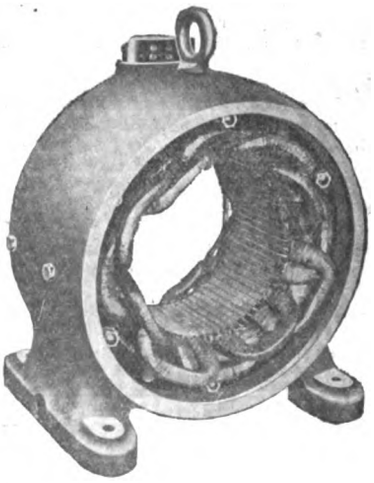

FIG. 3.—Stator of Rhodes Single-Phase Motor.

Referring to the accompanying illustration (Fig. 1), it will be seen that the external appearance of the machine is similar to that of the firm's continuous-current R. E. type motor. Figs. 2 and 3 show the rotor and the stator parts respectively. We have great pleasure in recording the advent of an English-built single-phase motor of such an obviously useful type as the above.

## THE DEADRECKONER.

Through the courtesy of Messrs. Siemens Bros. and Co., York-mansions, York-street, Westminster, S.W., we are able to illustrate herewith an instrument introduced by them for ascertaining a ship's position at sea by account. The "Dead-reckoner," as it is called, was invented by the Hon. Reginald

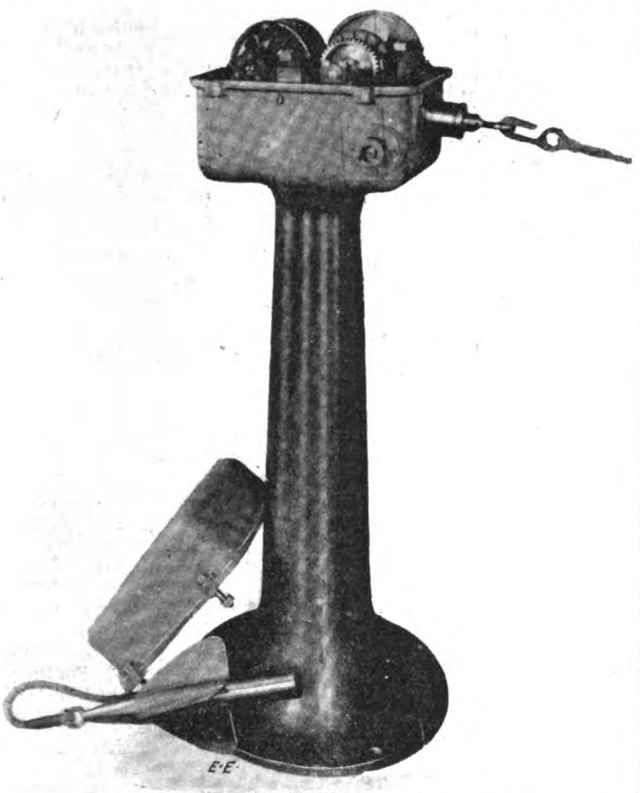

FIG. 1.—The Deadreckoner (Transmitter portion).

Brougham, and consists of two parts—the transmitter (Fig. 1), which is fixed on the poop, and the recorder (Fig. 2), placed in the chart-room. An electric cable forms the connecting link between them. Referring to Fig. 1, it will be seen that a shaft terminating in an eye projects from the after-end of the

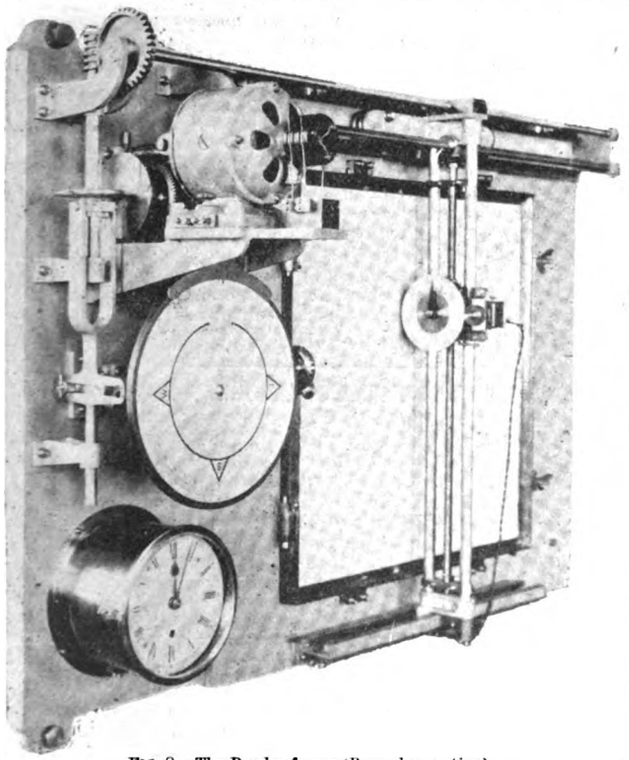

FIG. 2.—The Deadreckoner (Recorder portion).

transmitter box, and to this eye the rotator is connected by the usual log line. This shaft carries a worm which gears into a worm-wheel driving one half of a hunting switch, the other portion of the latter being driven through suitable gearing by a small three-phase synchronous motor. The action is as follows: As the portion of the hunting switch driven by the rotator is revolved, it makes a series of contacts with the portion driven by the motor. Directly the first contact is made the motor starts, and by revolving the other portion of the hunting switch breaks this contact and so comes to rest. If, however, the rotator continues to revolve, the motor will continue to run at a speed directly proportional to that of the rotator.

The recorder is mounted on a frame about 40in. by 30in., which carries two screw spindles at right angles to each other, one being termed the north spindle, and the other the east spindle. A time printing wheel is fixed on a nut carried by the former. Further, the spindles are connected by suitable worm gearing to two steel discs, which are free to slide upon the shafts on which they work. These discs are placed at right angles to two other discs connected together, which are revolved through suitable gearing by a synchronous motor similar to the one in the transmitting gear. The north and east discs, although free to move across the face of the other two discs, are connected together in a manner similar to the pistons of a two-cylindered steam-engine with cranks at 90deg. A "pelorus," divided into single degrees, is so geared to these discs that when an index points to the north point of the pelorus, the north disc is on the extreme edge of one of the discs driven the motor, and the east disc is exactly in the centre of the other disc. Similarly, when the index points to the east point of the pelorus, the east disc is on the extreme edge of one of the discs driven by the motor, and the north disc is in the centre of the other disc. Thus, at any position of the pelorus, the north and east discs will take up a position on their driving discs corresponding to the proportion of northerly or easterly direction as indicated by the pelorus. And so for all other points of the compass. The motor driving these two discs is connected in parallel with the motor on the transmitter, and being absolutely synchronous with it imparts a motion to the discs directly proportional to the speed of the rotator. Therefore the travel of the timewheel mentioned above will be directly proportional to the distance traversed by the ship, quite independently of the direction in which the timewheel travels. Now it has been shown that the direction of travel of the timewheel is controlled by the position of the pelorus relative to the index, consequently the line traced by the timewheel is, in length, directly proportional to the speed of the ship, and its course is that indicated by the pelorus. It may be mentioned that the timewheel referred to is normally held away from the paper by a spring, but every 15 minutes an electric current is sent by a clock, which forms part of the apparatus, to an electromagnet, which thereupon presses the wheel against the paper, printing on it the time as shown by the clock. The course is indicated by a series of dots, also printed by this timewheel. Further particulars of the "Deadreckoner," together with full directions for using it, are contained in a pamphlet just issued by Messrs. Siemens Bros. and Co., Limited.

## PERSONAL.

The Electric Light Committee of the Coventry Corporation have reconsidered the application of Mr. J. A. Jeckell, the manager of the electricity department, for an increase of salary, and have decided to adjourn the same until after the issue of the balance-sheet for the past year's trading.

Mr. William Augustus Kemm has been appointed chief electrical engineer to the Battersea Borough Council out of 63 applications. Mr. Kemm graduated at Haysman's University College, Hampstead; St. Joseph's College, Grammont, Belgium; and City and Guilds Technical College, Finsbury. He was engineer-in-charge and mechanical and electrical assistant, St. Pancras Vestry, from 1892 to 1898; chief assistant electrical engineer, Canterbury Corporation from 1898 to 1901; and has been chief assistant electrical engineer, Battersea Borough Council, since May, 1901.

On Friday evening last Mr. F. Gill, senior cash clerk (who is severing his connection with the Huddersfield Corporation tramways after 21 years' service), was presented with a gold curb albert and engraved medal attached. Mr R. H. Wilkinson, general manager, presided over the gathering and was supported by Mr. T. Hartley, traffic superintendent, and other heads of departments. Mr. I. Pogson, motorman, one of the oldest employés, made the presentation.

Sir Charles Todd, K.C.M.G., Deputy Postmaster-General for South Australia and well known in connection with the overland telegraph line, has retired from public service.

The Highways Committee of the London County Council are considering a number of increases of salary in the permanent staff, which includes officials in the tramway department.

A private meeting of the Exeter City Council was held last week under the presidency of his Worship the Mayor (Mr. E. C. Perry) to, according to the agenda, "enquire into the question as to the competency of the electrical engineer to discharge the several duties devolving upon him, and to make such report to the Council as may be determined upon." No specific charges were brought against the electrical engineer. Mr. Munro (the chairman of the Finance Committee) severely criticised the electric light undertaking from a financial point, and the discussion was chiefly directed to this side

Digitized by Google

of the subject. It was eventually resolved that the general management of the undertaking and also the question of the competency of the electrical engineer, should be referred to a special committee to report, to which no member of the Electric Light Committee, with the exception of the chairman, is to be elected. Finally, Mr. Reed, the chairman of the Electric Light Committee, having intimated that he might not be able to devote sufficient time to the matter, it was agreed that his place should be taken by the vice-chairman, Mr. W. Wreford.

## WALSALL ELECTRICITY ACCOUNTS.

The accounts of the Walsall electricity department for the year ended Dec. 31, 1904, show a total expenditure on capital account to that date of £86,405. Abstracts of the revenue account, balance-sheet, and statement of electricity generated, sold, etc., are appended.

| Dr. REVENUE ACCOUNT. | £ | s. | d. |
|---|---|---|---|
| Generation of electricity | 3 789 | 0 | 2 |
| Repairs, etc., of buildings and plant | 1,248 | 13 | 10 |
| Distribution of electricity | 201 | 0 | 10 |
| Attending and repairs to public lamps | 77 | 0 | 3 |
| Rents, rates, and taxes | 631 | 11 | 8 |
| Management expenses, salaries, etc. | 801 | 9 | 0 |

# LEGAL INTELLIGENCE.

## INJURY TO WORKMEN.

### Kay v. the British Westinghouse Electric and Manufacturing Company, Limited.

The defendants applied to the Court of Appeal on Friday last for a new trial or judgment in an action tried before Mr. Justice Jelf and a special jury at Manchester Assizes. The action was brought to recover damages for personal injuries. The plaintiff was an ironturner in the employment of the defendants. The plaintiff alleged that on Feb. 22, 1904, while he was so employed, the defendants, in breach of their statutory duty in that behalf imposed by Section 10 (*c*) and (*d*) of the Factory and Workshop Act, 1901 neglected and omitted securely to fence all the dangerous parts of the machinery in their factory; and that by reason of the premisses the plaintiff, while engaged in his employment and while proceeding along a certain passage to a clock-off, came into contact with a switchboard, and his face was drawn on to the blades of the switchboard and held there by the electric current and set on fire, and the plaintiff sustained thereby terrible injuries which permanently incapacitated him from following his employment. The defendants by their defence denied that the switchboard or the blades thereof constituted dangerous machinery, or that the same constituted machinery at all within the meaning of the Factory and Workshop Act, 1901. In the alternative, they pleaded that, if the switchboard or the blades thereof were in an unsafe or dangerous or improper condition, such condition existed without any default or neglect on the part of the defendants. The jury returned a verdict for the plaintiff for £850. The defendants now moved for a new trial on the ground that the learned judge had misdirected the jury, or, in the alternative, for judgment.

In dismissing the application without calling upon counsel for the plaintiff, the **Master of the Rolls** said that the direction of the learned judge in the court below was substantially correct, and that there was abundant evidence that this system of lighting, if unprotected, was defective. The directors substituted a competent manager for themselves. But if that manager was negligent, and knowledge of his negligence was brought home to them, could they rely on the fact that they had substituted him for themselves? In his opinion they could not, because the antecedent underlying obligation to supply adequate materials and resources remained, and there was an obligation on them to rectify the mistake. The evidence showed that the mischief which caused the plaintiff's injuries had already attracted the notice of a Board of Trade inspector, who sent the company a formal notice with regard to it. One of the directors was asked about that, and he said he had no doubt that the specification for dealing with the matter was laid before the Board. The fact that the switchboard was unprotected must, therefore, have been known to the Board. The conclusion to which he came was that there was sufficient to saddle the directors with the duty of dealing with a crying danger. He thought there was abundant evidence of negligence on the part of the manager inadequately repressed by the directors. In his opinion, therefore, the appeal failed. It was not necessary to give any opinion on the question as to machinery.

**Mathew and Cozens-Hardy, L.J.**, concurred.

## TRAMLINES AND MOTOR OMNIBUSES.

Judgment was given on Saturday in the case of T. Tilling, Limited, *v.* Dick, Kerr, and Co., Limited, reported in our last week's issue.

**Mr. Justice Warrington** said the defendants pleaded that the obstructions were placed in the road under statutory authority, and that they were protected by Act of Parliament. The plaintiffs said that in any case the defendants were guilty of negligence, and were therefore liable. He, however, held that negligence was not proved. The London County Council had purchased the South London tramways, and had converted them from horse traction to electric traction. The defendants were contractors for the work, and were responsible for all damage caused by the interference with traffic. For the purpose of maintaining the trams on a double line of rails, and with a desire to interfere as little as might be with the ordinary traffic, the defendants laid between the kerb on one side of the road and the permanent tramway a temporary line of rails, at the same time closing altogether the other half of the road. The temporary line projected above the surface of the road about 2in., and he found that the raised rails were an obstruction to the highway, and caused damage to plaintiffs' omnibuses. There was evidence that it would have caused great public inconvenience to interrupt the service of cars, and that less interference to ordinary traffic was caused by the construction of a turn-out than by carrying on the tram service on a single line with cross-overs at intervals. He could not adopt the defendants' construction that they were authorised by statute. In his opinion the works they had constructed were not necessary for adapting the tramways to be worked by electricity, but were necessary, if at all, for maintaining the tramcar service uninterrupted. Works for this purpose were not covered by the Act, and the defendants were accordingly not protected by it. There arose the question whether as to the cause of the action arising more than six months before the date of the writ the action was barred by the 56 and 57 Vic., cap. 11, the Public Authorities Protection Act, 1893. In the absence of authority, he should have been prepared to hold that contractors undertaking work for their own profit were not within the protection of this Act, and this view was supported by a decision of the Court of Appeal. In his opinion the plaintiffs were entitled to the relief they asked. The damages were to be ascertained by some form of reference. The defendants must pay the costs up to and including judgment.

It was agreed to refer the question of damages to the Official Referee and to stay the reference until after the appeal had been heard.

## BRIGHTON CORPORATION'S APPEAL.

The Corporation's appeal in the action brought against them by Macartney, McElroy and Co., reported in our last week's issue, again came before the Master of the Rolls and Lords Justices Cozens-Hardy and Mathew last week, when, evidence having been taken on the Wednesday, Mr. Fletcher Moulton, K.C., intimated on behalf of the Corporation that he would not trouble their lordships further.

As the result of a consultation between counsel for the respective parties, judgment will be entered for an agreed amount.

The Master of the Rolls intimated that the parties had arrived at a very judicious arrangement.

## APPOINTMENTS VACANT.

**Electrical Engineer**, Great Western Railway. Salary £600 per annum. Applications by Feb. 27. See advertisement in previous issue.

**Inspector of Telephones**, Brighton Corporation. Applications by March 4.

**Mains Superintendent**, Carlisle. Salary £120 per annum. Applications to Corporation's Electricity Works by Feb. 28.

**Permanent-Way Superintendent**, Blackburn Corporation. Wages, £2. 10s. per week. Applications by March 3. See advertisement.

# COMPANIES' MEETINGS AND REPORTS

## NORTHAMPTON ELECTRIC LIGHT AND POWER.

The annual meeting of this Company was held at the Northampton Town Hall on Saturday, Mr. F. H. Thornton, J.P. (the chairman), presiding. Particulars of the report appeared in our last week's issue.

In moving the adoption of the report, the **Chairman** said the accounts were even better than they appeared, for they were allowing £600 more for depreciation and carrying forward £316 against £209. They had a most efficient staff, and had greatly improved their machinery. With regard to the new shares, the 5 per cent. preference had all been taken up, and the ordinary shares had been well applied for. They proposed in the near future to pay off the 6 per cent. preference shares, which would cost £800; and then, when they had a little more money, to write off the founders' shares, which would cost another £1,000. The chairman then quoted a report of the Phœnix Fire Office to show that electric light was the safest illuminant when it was properly installed, and said that in Northampton steps were taken to ensure that proper installations were made.

The report was unanimously adopted.

The chairman and Mr. W. Tomes, J.P., were re-elected as directors, and Mr. B. Hesleden as auditor. A sum of £200 was unanimously voted to the directors as remuneration.

## MARCONI WIRELESS TELEGRAPH.

The annual meeting of this Company was held on the 16th inst., Sir Charles Euan Smith presiding. Particulars of the report appeared in our issue of the 10th inst.

The **Chairman** observed that they had made a profit of £12,681, and that without any adventitious aid or subsidy, as was the case in 1902 and 1903. It was not claimed that the system was in full working order. What the directors did say, however, was that they had laid the basis for their future operations, and that the contracts they had entered into had placed them in a position for reaping whatever future benefits there might accrue from wireless telegraphy such as no other system could attain. They were on the brink of completing the machinery for a regular Transatlantic service, and the estimated earnings per annum of a single pair of stations was £56,000. The capital cost of a pair of stations was but £250,000, as against £800,000 for a single Transatlantic cable. Ships carrying their apparatus were steadily increasing in number, and were thus establishing a large Marconi exchange. The agreement with the Postmaster-General had already borne fruit in the shape of the notice issued in January stating that messages would be collected at all post offices throughout the country for transmission through the Company's shore stations to ships at sea. They had further cemented their connection with the Post Office by consenting, at its request, to conduct a wireless service with the Scilly Islands during the recent breakdown of the ordinary means of communication.

The report was adopted.

## CHELSEA ELECTRICITY SUPPLY.

The report of the Chelsea Electricity Supply Company, Limited, for the year ended Dec. 31, 1904, submitted at the meeting on the 22nd inst., states that the profit for the year amounts to £35,053, which, with £1,200 brought forward, makes a total of £36,263. The directors recommend placing to credit of renewals and depreciation fund £10,344 and after paying a final dividend on the ordinary shares at the rate of 7½ per cent. per annum (making 6 per cent. for the year), there remains to be carried forward £1,170. Further expenditure, amounting to £3,875, has been incurred during the year in connection with changing the system of supply from 100 volts pressure to 200 volts. This amount has been added to the suspense account, from which £3,362 has been written off, leaving that account at £4,725. The number of lamps connected on Dec. 31, 1904, was 210,659, an addition of 15,424 during the year. The improvement in the units sold per lamp continues. The total number of units sold in 1904 was 3,212,412, being 473,060 more than the previous year. During the year an issue of £25,000 debenture stock was made at the price of £107. 10s., and the net premiums, amounting to £1,664, have been carried to debenture stock premium redemption fund. Reference is made to the lamented death of Major-General C. E. Webber, one of the first directors. It is not proposed to fill the vacancy.

## YORKSHIRE ELECTRIC POWER.

The report for the half-year ending Dec. 31, to be submitted to the shareholders on the 28th inst., states that since the meeting held in August, 1904, the buildings connected with the Thornhill power station have been completed, and with the exception of the turbo-generators, all the plant has been delivered and installed. The first two of the turbo-generators are completed and are now being tested at the makers' works at Rugby, and it is anticipated that they will be erected in the station during the month of February. The directors are glad to report that in accordance with their promise to the shareholders, a supply of electricity was available at the works before the end of December, and the first consumer was connected on Jan. 21, 1905. In addition to the agreement with the Urban District Council of Mirfield, agreements have been entered into with the Corporation of Pudsey and the Urban District Council of Liversedge for a supply in bulk, the agreement with the latter, as with the Mirfield Council, enabling the Company to supply large power users direct. Negotiations are proceeding with other local authorities, and agreements have been made with several large users of energy for power purposes in the districts in which mains have been already laid.

## LONDON ELECTRIC SUPPLY.

The report for the year ending Dec. 31, 1904, states that the profit on the working for the year is £65,333. 6s. 4d., to which has to be added interest on deposit and the amount brought forward, £2,137. 0s. 9d., making a total of £67,470. 7s. 1d. Out of this the interest to Dec. 31—viz., £15,478. 5s. 11d.—has been paid, leaving a balance of £51,992. 1s. 2d. The Board propose to pay a dividend of 6 per cent. on the preference shares for the year ended Dec. 31, 1904 (of which an interim dividend of 3 per cent. was paid on Sept. 1), to pay a dividend of 3 per cent. on the ordinary shares, to place to reserve account, to provide for contingencies, and to carry forward £2,009. 10s. 8d. The number of units sold during the year amounted to 10,531,785, as compared with 4,102,099 during 1903. The capital expenditure for the year was £49,377. 15s. 8d., necessitated by the expansion of the Company's business.

## CAMBRIDGE ELECTRIC SUPPLY.

The report for the year ending Dec. 31 states that during the year 1904 there has been added to the Company's mains the equivalent of 3,074 8-c.p. lamps, making a total to date of 47,112. The number of units supplied has been 523,298, an increase of over 51,000 units. After paying all charges, and placing £1,000 to depreciation fund account, the accounts of the Company show a balance of £6,691. 17s. 9d., which, added to £1,342. 9s. 6d. brought forward from last year, makes £8,034. 7s. 3d. An interim dividend of 2½ per cent. (£1,903. 4s. 3d.) has already been paid, and after deducting debenture and other interest (£455. 2s. 2d.) there remains a net balance of £5,676. 0s. 10d. Out of this the directors recommend the payment of a dividend of 4½ per cent.—making 7 per cent for the year. This will absorb £3,959. 5s., leaving a balance to carry forward (subject to fractional adjustment of income tax) of £1,716. 15s. 10d.

## SOUTH METROPOLITAN ELECTRIC LIGHT AND POWER.

The report of directors for the year ended Dec. 31, 1904, states that the revenue account shows a credit balance of £16,574. 16s. 3d., which, with £5,219. 19s. 1d., the balance brought forward from the previous year, makes a total of £21,794. 15s. 4d. After deducting £6,323. 18s. 6d. for interest on debenture stock paid and accrued, and for other interest, and £1,750 for interim dividend paid on 7 per cent. cumulative preference shares, there remains a balance of £13,720. 16s. 10d., which the directors propose to deal with as follows: To payment of final dividend to Dec. 31, 1904, upon the amounts paid up on the 7 per cent. cumulative preference shares, £2,439. 6s. 8d.; to credit of depreciation account, £2,250; to write off change over system in Greenwich account, £824. 19s. 11d.; in reduction of preliminary expenses account, £1,500; and to carry forward to the next account, £6,706. 10s. 3d. The business of the Company continues to show a large advance over preceding years. The Company took over the undertaking of the Crystal Palace District Electric Supply Company on June 16 last. The number of lamps added by the inclusion of this area was 29,572, and the accounts submitted include the returns of this business from that date. The change of system from direct to alternating current in the new area is being carried out as rapidly as possible, and should be completed before the end of the present year, when the Company will benefit by more economical working. The Urban District Council of Beckenham have served notice on the Company, exercising their statutory right to purchase a small portion of the new area, and the purchase price is now being adjusted.

## TELEGRAPH CONSTRUCTION AND MAINTENANCE.

The report for the year ended Dec. 31, to be submitted at the forty-first ordinary meeting on the 28th inst., states that there is a net profit of £48,825. 15s. 11d. after charging the interest on the debentures. To this sum must be added £120,483. 17s. 3d. brought forward from last year, making a total of £169,309. 13s. 2d. From this amount is deducted the interim dividend of 5 per cent., paid July 12, 1904, amounting to £22,410, leaving £146,899 13s. 2d. to be dealt with. Of this sum the directors propose to distribute a dividend of £1. 4s. per share, absorbing £44,820, being at the rate of 10 per cent., and making, with the amount already paid, a total dividend for the year of £1. 16s. per share, or 15 per cent., free of income tax, leaving £102 079. 13s. 2d. to be carried forward to the next account. Various lengths of cable have been manufactured, and sundry cable-repairing operations have been carried out, but the work generally has not been on so extensive a scale as during the past few years. The Company's factories at Greenwich and Wharf-road have been well and properly maintained. Advantage has been taken of the slackness of work to rebuild a portion of the factory at Greenwich, and to introduce improvements there which will add to the efficiency of the works. The Company's steamships are in good and thorough repair. The directors have every reason to believe that the "Camoria," launched on Nov. 22, will prove a valuable addition to the Company's cable fleet.

## IMPERIAL TRAMWAYS.

The report for the year ended Dec. 31, to be submitted at the ordinary general meeting to-morrow, states that the gross receipts from the Middlesbrough, Stockton, and Thornaby electric tramways amounted to £51,097. 4s. 4d., and the number of passengers carried was 9,818,349, compared with totals of £49,963. 7s. 7d. and 9,576,125

Digitized by Google

in the preceding year. The net profit for the year is £16,564. 14s. 9d. The directors are pleased to be able to report that the Bill promoted by the Company last session received the Royal assent on Aug. 15 last. Under it the Company is empowered to construct a line of tramways, 4 miles 4·70 chains in length, commencing at the termination of the Company's existing system in Middlesbrough and running through the populous manufacturing districts of North Ormesby, South Bank, Grangetown, and Eston. The Company's interest in the London United Tramways (1901), Limited, has been slightly increased during the past year, and is now represented by 44,446 fully-paid 5 per cent. cumulative preference £10 shares. There is a corresponding increase in the dividends on these shares, which amount for the year to £21,135. 0s. 1d. net as shown in the revenue account. It will be seen that the Company's net revenue account for the year shows an available balance of £41,655. 15s. 3d., and after payment of interest on the debenture stock for the whole year, and interim dividends on the preference and ordinary shares in respect of the half-year to June 30 last, amounting together to £26,168. 4s. 7d., it is proposed to appropriate the balance as follows: dividend at 6 per cent. per annum on the preference capital (paid on Jan. 2 last), £5,700; final dividend at 10 per cent. per annum (making 9 per cent. for the year) on the ordinary capital (less income tax), £9,500; and to carry forward to the next account £287. 10s. 8d. The reserve funds now amount to £121,871. 14s. 7d.

## NATIONAL TELEPHONE.

The report for the half-year ended Dec. 31 last states that the income accrued in respect of the business of the half-year amounts to £1,033 705, as compared with £941 259 for the corresponding period of 1903, being an increase of £92,446. The working expenses for the half-year amount to £591 635, as compared with £527,284 for the corresponding period of 1903 being an increase of £64 351. The net result for the half-year (after deducting the Post Office royalties, amounting to £295 193) is a profit balance of £346,874, as compared with £327,739 for the corresponding period of 1903, being an increase of £19,135. The rentals carried forward for unexpired terms of running contracts amount to £889 577, as compared with £827,163 at the corresponding period of 1903, being an increase of £62,413. Out of the available balance of £274,057 shown by the net revenue account, the Board will recommend the payment for the half-year of a dividend at the rate of 6 per cent. per annum on the first and second preference shares, 5 per cent. per annum on the third preference shares, 6 per cent. per annum on the preferred stock, and 5 per cent. per annum on the deferred stock, less income tax in all cases. The Board also propose to transfer £115,000 to the reserve fund and to carry forward the balance of £10,141. The sum of £402,101 has been expended on capital account during the half-year in the erection of 18,625 additional exchange and private stations and in the construction of underground works. Allusion is made to the agreement just arrived at with the Postmaster-General.

## LONDON UNITED TRAMWAYS.

The report for the year ended Dec. 31 last states that the operation of the Company's undertaking during that period resulted in gross receipts amounting to £296.235, and the working and general expenses and renewals to £176,188, leaving, with the balance brought forward from last account, a net revenue of £120,834. After payment of debenture interest and dividend on the 5 per cent. preference shares for the year, there remains £42,087 (including £3,750 net premiums on new preference shares). It is proposed to pay a dividend of 6 per cent. on the ordinary shares, an interim payment in respect of which was made last August; to place £5,000 to the credit of a reserve fund, and to carry the balance of £563 forward. The gross receipts show an increase of £15 993, whilst the operating expenses have decreased by £203, notwithstanding the larger mileage open as compared with the previous year. The total number of passenger carried was 48,126,727, an increase of 2 833,254. The extension from Southall to Uxbridge, *via* Hayes and Hillingdon, and also the connecting line from Hammersmith Broadway *via* Askew-road, were opened for public traffic in June last, and the results have fully realised anticipations. The Bill promoted by the Company in the last session of Parliament to authorise an extension from Hounslow to Staines received the Royal assent on Aug. 15. Preparations are in progress for the construction of the authorised tramways in Kingston, Surbiton, the Maldens, and Wimbledon, and between Brentford and Hanwell. These Surrey lines will link up important centres of population, and will connect with the London County Council electric tramways system at Tooting, and over Kingston Bridge with the Company's tramways in Middlesex and London.

## NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY.

The report for the year ending Dec. 31 states that the total units sold during the year amounted to 17,132,153, which, compared with the previous year's figures of 9,033,625 units, shows an increase of 8,098 528. Of the units sold in the past year, 14 000,000 have been sold for power purposes, the remainder being for lighting only. The profits for the year, including the balance of £1,099. 0s. 8d. brought forward from 1903, amount to £52 539. 8s. 7d., out of which there have been paid: interest on debentures and loans, £14,256. 19s. 10d.; interim dividends, paid in July last, of 2½ per cent. on the amount called up on the whole of the preference and ordinary shares, £14 278. 7s. 6d.; and the balance of extra cost in connection with the electrical undertaking purchased from the Walker and Wallsend Union Gas Company, £1,500—leaving an available balance of £32,504. 1s. 3d., which the directors recommend should be appropriated as follows; in the payment of a further dividend of 2½ per cent. on the amount called up on the whole of the preference shares, and of 5½ per cent. on the amount called up on the ordinary shares, making total dividends of 5 per cent. and 8 per cent. respectively for the year, which will absorb £24,405. 0s. 10d.; in the payment of a dividend of 3½ per cent. on the ordinary shares allotted in connection with the purchase of the Walker and Wallsend Union Gas Company's electricity undertaking, making 6 per cent. on these shares, £1,226. 11s. 6d.; in writing off to depreciation account the sum of £6,000; and leaving to be carried forward to next year, £872. 8s. 11d. During the latter half of the year the North-Eastern Railway Company has been regularly supplied with electrical energy for traction, as well as for power and lighting purposes. The total expenditure on capital account during the year has been £124,242, representing outlay in completing the new power station at Carville, as well as other developments in the Company's area. The Carville station, the construction of which began in 1903, was put into commercial operation during the latter half of the year. An agreement has been entered into with the Northern Counties Electricity Supply Company, Limited, by which the working and developing of the districts of Whitley, Monkseaton, Earsdon, and Seghill, covered by provisional orders granted to that company, have now been transferred to this Company. The supply of electricity in Whitley and Monkseaton has been available for some time, and it is expected that this area will be a profitable acquisition to the Company's business. The payment of £13,684. 19s. 7d. made to the Northern Counties Company is for the provisional orders, plant, cables, etc., in the above-mentioned districts. The shareholders will be asked to confirm a provisional agreement which has been entered into for the purchase of the whole of the shares issued by the County of Durham Electrical Power Distribution Company, Limited. This scheme, if sanctioned, will largely increase the Company's output, and, being a matter of special importance, forms the subject of a separate report, which will be in the hands of the shareholders before the meeting.

An extraordinary meeting will follow the general meeting on March 2 for the purpose of effecting alterations to the articles of association.

## HART ACCUMULATOR.

The report for the year ended Dec. 31 states that the profit amounts to £5,813. 0s. 4d., and the balance brought forward from last year £5,737. 10s. 8d. After deducting the dividend on preference shares, £137. 17s. 8d., the balance standing to the credit of profit and loss account is £11 412. 13s. 4d. The directors recommend the payment of a dividend of 12½ per cent. per annum on the ordinary share capital, which will absorb £5,000, leaving £6,412. 13s. 4d. to be carried forward. The Company's buildings, plants, tools, etc., have been augmented by £4,261. 17s. 1d., which has been charged to capital, and due depreciation on same has been made. The maintenance of the works, plant, etc., has been well kept up at a cost of £799. 13s. 11d., which has been paid for out of revenue. The retiring directors are Messrs. L. W. Spratt and S. W. Hart, who, being eligible, offer themselves for re-election.

## NEW COMPANIES REGISTERED.

**Electric Flash Lights, Limited.**—Capital, £25,000. Objects: to acquire from B. Sherman, of 16 and 17, Devonshire-square, London, the benefit of certain existing inventions relating to electric flash-light advertising; to adopt an agreement with the said vendor, and to carry on the business of advertising agents and contractors, electrical engineers, manufacturers of and dealers in all kinds of electrical machinery, fittings and appliances, etc.

**Zea Arc Lamp Company, Limited.**—Capital, £1,000. Object: to carry on the business of lamp manufacturers, suppliers of electric light, electricians, engineers, etc., and, in particular, to take over from E. G. Abrahams, of 2, Staple-inn, London, the benefit of certain inventions relating to arc lamps. Registered office: 2, Staple-inn, Holborn.

### Lien Registered.

**Anglo-Argentine Tramways Company, Limited, London, E C.** Lien registered Jan. 23, for securing an annual sum of £71,060 during a period of 80 years, from Jan. 1, 1905, reducible in certain events to £70,860 and £70,060, and interest on instalments in arrear (if any); holder: City of Buenos Ayres Tramways Company (1904), Limited; secured by a floating charge on the net receipts of the entire undertaking, after payment of 6 per cent. interest on an issue of debenture stock not exceeding £266,600, and current working expenses.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Salamanca.**—The Municipality requires tenders for public electric lighting. Tenders by March 14.

**Bucharest.**—The Telegraph Department require 3,000 kilos of sulphate of copper. Tenders by March 7.

**Salford.**—Tenders are required by the Corporation for the alteration of storage batteries. Tenders by March 4.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**Leeds.**—The Corporation require tenders for the complete equipment of two sub-stations. Tenders by March 14.

**Croydon.**—Tenders for the annual supply of coal at the electricity works for the year ending March 31, 1906, will close on Feb. 28 at 11 a.m.

Digitized by Google

**Barcelona.**—The Municipality require tenders for arc lighting of La barriada de San Gervasio de Cassolas. Tenders by March 15.

**Bucharest.**—The Post and Telegraph Department require tenders for 13,000 kilos 3mm. bronze wire and 120 kilos soft 1·5mm. copper wire.

**Bucharest.**—The Post and Telegraph Department require tenders for 14,000 large, 8,000 medium, and 3,000 small insulators. Tenders by March 16.

**Fulham.**—The Borough Council invite tenders for the supply of electrical stores for year ending March 31, 1906. Tenders by 4 p.m. on March 15.

**Plymouth.**—The Corporation invite tenders for the supply of electricity meters, transformers, and cables (paper insulated). Tenders by March 18. See advertisement.

**Bucharest.**—The Roumanian Government Railways require tenders for telegraph poles as follows: 2,000 7m. long, 2,000 8m. ditto, and 500 9m. ditto. Tenders by March 10.

**King's Lynn.**—The Corporation invite tenders for one 200-kw. steam dynamo, condenser, steam and other pipes. Tenders by 28th inst. See advertisement in previous issue.

**Hull.**—The Electric Lighting Committee invite tenders for the supply, etc., of mains and cables for 12 months. Tenders by 12 noon on March 1. See advertisement in previous issue.

**Ilford.**—The Council require tenders for the annual contracts for the year ending March 31, 1906, for the electricity department. Tenders by Feb. 27. See advertisement in last issue.

**Stoke Newington.**—The Council invite tenders for the supply, delivery, and erection of sub-station plant and mains. Tenders by 4 p.m. on March 8. See advertisement in previous issue.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Battersea.**—The Council require tenders for the supply for one year from March 31 next of electricity meters, joint-boxes, carbons, coal, and oil stoves. Tenders by Feb. 27.

**Shoreditch.**—The Council invite tenders for their yearly contracts in the electricity works and other departments. Tenders by March 14. Full particulars in our advertisement columns.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Madrid.**—The Post and Telegraph Department, Calle de Carretas 10, require tenders for telephone and telegraph apparatus, estimated at 35,337·50 pesetas. Tenders by March 10. This includes 50 Morse receivers.

**Lowestoft.**—The Corporation invite tenders for one water-tube boiler with superheater, brickwork settings, and accessories, together with the necessary pipework. Tenders by March 9. See advertisement in previous issue.

**Newport (Mon.).**—Tenders are invited for the installation of electric light, electric bells, and heating and hot-water apparatus in the new police station, Alexandra-road. Tenders to the Borough Engineer by 10 a.m. on March 2.

**Manchester.**—The Tramways Committee of the Corporation invite tenders for the supply of cement, chippings and broken stone, veterinary services, and general stores. Tenders by March 6. For full particulars see advertisement.

**Dax (France).**—Tenders are required for a concession to erect and work electric lighting of the town for 35 years. Particulars may be obtained from the Secretary to the Municipality of Dax, Province of Landes, France. Tenders by March 6.

**Great Western Railway.**—The directors invite tenders for the supply, delivery, and erection of plant in connection with their electricity generating station at Park Royal and proposed sub-stations and distributing centres at various places. Tenders by March 13.

**Wimbledon.**—The Urban District Council invite tenders for the supply of (3) engine-room stores, (4) cables, (5) joint-boxes and jointing materials, (6) transformers, (7) meters, (8) oils, (9) incandescent electric lamps, carbons, and accessories, (10) iron castings. Tenders by March 4.

**Madrid.**—Der Compania Electrica Madrilena de Traccion propose to extend their electric tramways from the Barquillo-street to Olivide-place. The concession for the works will be dealt with by the Public Works Department, Madrid, April 2. Tenderers for same must deposit a guarantee of £96.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Newport (Mon.).**—The Electricity and Tramways Committee invite tenders for 300-kw. continuous-current high-speed tramway generator (engines of enclosed type), 200-kw. continuous-current high-speed steam balancer (engines of enclosed type), boiler, switchboard, stores, etc. Tenders by March 6. See advertisement.

**Edinburgh.**—The Corporation invite tenders for the annual supply of arc lamp carbons, cast-iron pavement and road boxes, electricity meters, house service fuse-boxes, earthenware trunking for laying electricity cables on the solid system, bitumen, and arc lamp globes. Tenders by March 13. See advertisement.

**Glasgow.**—The Corporation invite tenders for supplying and erecting electric light installation, etc., required in the new central police office. Specifications and forms of tender may be had on application at the Office of Public Works, City Chambers, 64, Cochrane-street. Tenders to the Town Clerk (Police Department) by 27th inst.

**Gloucester.**—The Electricity Supply Committee invite tenders for three Lancashire boilers and accessories, one 600-kw. generating set and accessories, electrically-driven surface-condensing plant to deal with 30,000lb. of steam per hour, steam, exhaust, feed, drain, condensing water, and sundry pipes, valves, etc., and an electrically-driven boiler feed pump, the whole bound up in one specification. Tenders by March 16. See advertisement.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**South Shields.**—The Electricity Supply Department invite tenders for the supply, delivery, and erection of the following plant: (Contract No. 67) one multitubular marine-type boiler, with chimney and mountings; (68) two medium-speed open-type vertical engines for two 550-kw. direct-current traction generators; (69) two 550-kw. direct-current traction generators; (70) traction switchboard; tramways department—(Contract No. 4) electric tramcars, complete with "Brill" trucks, for the Corporation. Copies of specifications, conditions, form of tender, also form of contract, can now be obtained from Mr. J. H. Cawthra, M.I.E.E., borough electrical engineer, South Shields, on payment of £2. 2s. for each contract, which sum will be returned on receipt of a bona fide tender for each contract. Tenders to Mr. J. Moore Hayton, town clerk, Court-buildings, South Shields, by noon on March 13.

**Johannesburg.**—The Municipal Council are prepared to receive tenders for 100 electric tramcars, two electric water-cars, one five-ton travelling crane, one electric car traverser, and various workshop tools, including erection at Johannesburg, to Specification No. 10 of their consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W. Copies of the specification may be seen on and after Jan. 7 at the Council Offices, Johannesburg, and at the Consulting Engineers' Offices in London, and may be obtained on payment of five guineas, which will be returned on receipt of a bona fide tender. Duplicate copies of the specification may be bought for 10s. each (not returnable). Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W., and must be received by them not later than March 6. The Council will not be responsible for any expenses incurred in tendering.

## RESULTS OF TENDERS.

**Hammersmith.**—The Borough Council have accepted the tender of the Western Electric Company, London, at £1,057. 3s., for cables.

**Islington.**—The Borough Council have accepted the tender of Messrs. Graham-Morton and Co. for the supply of an ash elevator, at £112.

**Sheerness.**—Messrs. Johnson and Phillips have secured the contract from the Admiralty for two direct-current dynamos for the Sheerness Dockyard.

**Carlisle.**—The Town Council have accepted the terms of the Tudor Accumulator Company for the supply of a battery of 256 cells, type No. L.D. 13, at £725.

**Yarmouth.**—The following tenders have been recommended for acceptance: Brush Electrical Engineering Company, tramcars £5,646, electrical overhead equipment £2,357; F. Dennis and Co., railbonds, £480. 9s.

**Rochdale.**—The Corporation have accepted the tender of the British Thomson-Houston Company, Rugby, for high-tension three-phase switchgear and extensions to the low-tension continuous-current switchboards.

**India.**—The contract for supplying 10 passenger locomotives and tenders for service on the Indian State Railways has been placed with Messrs. Robt. Stephenson and Co., Limited, of the Springfield Locomotive Works, Darlington.

**Bournemouth.**—The contract for the extension of the Bournemouth and Christchurch tramways has been let to J. G. White and Co., Limited, London. There are six miles of track and three of route, and the amount of the contract is £39,000.

**Bradford.**—The Corporation have accepted the tender of Messrs. Bolckow, Vaughan, and Co., Limited, Middlesbrough, for supply and delivery at Bradford of 400 tons of steel girder tramrails and 20 tons fishplates, for electrical equipment of tramways.

**Neath.**—The Corporation have accepted the tender of Messrs. Evershed and Vignoles for an Evershed's "Megger" testing set, arranged for 250 volts and reading up to 20 megohms, at £17. 5s.; and that of the British Westinghouse Electric etc., Company, Manchester, for wattmeters of 5, 10, 20, 40, 80, 120, 200, 400, and 800 amperes, at £3. 5s., £3. 15s., £4. 10s., £5. 5s., £6. 6s., £7. 5s., £8. 8s., £10. 10s., and £15. 15s. respectively.

**Battersea.**—The Lighting Committee have accepted the tenders of Messrs. J. Oswald and Son to purchase and remove the damaged gas lamp columns, old iron, etc., at the central electric generating station, at 39s. per ton; Messrs. Babcock and Wilcox, Limited, to supply and fix three water tube boilers at the central electric generating station similar to those already erected there and fitted with chain grate stokers, at £3,600; and the National Boiler and the General Insurance Company, Limited, to inspect and test during construction, the three boilers referred to, for the sum of £8. 8s. each boiler.

---

**Aberdeen.**—The Corporation have decided to take proceedings against the Suburban Tramways Company to recover £700 spent in the alteration of street levels, unless the matter is settled amicably.

Digitized by Google

# BUSINESS NOTES.

## TRACTION.

**Perth.**—The work of reconstruction is now proceeding apace.

**Cardiff.**—The Corporation have decided against advertisements on the cars.

**Wellingborough.**—The Northants County Council have decided to lodge a petition against this Tramway Bill, the company not having agreed to the amendments suggested by the Council.

**Belfast.**—The arbitration proceedings have been concluded. The differences between the contractors and the workmen have been settled, and the work of reconstruction has been resumed.

**Derby.**—In addition to the Kedleston-road route, the Tramways Committee have decided to recommend the Council to proceed with an extension connecting the Pear Tree and Upper Dale-road routes.

**Leeds.**—The Tramways Committee on Tuesday decided to adopt a uniform 1d. stage of two miles, to make an experiment with ½d. fares on two more routes, and to grant further concessions to workmen and children.

**Pontypridd.**—Colonel Druitt inspected the Treforest line last week on behalf of the Board of Trade. The trial trip is reported to have been very satisfactory, and it is expected that the line will be opened on March 6.

**Portsmouth.**—The extension of the electric tramway on the Gosport side of Portsmouth Harbour is nearing completion. The intention is to ultimately connect this railway with Fareham, and afterwards with the light railway at Cosham.

**Stirling.**—The whole question of acquiring the Stirling and Bridge of Allan Tramway Company's system was discussed at the meeting of the Town Council, who ultimately decided not to purchase at present, but to give every encouragement to private enterprise in providing an improved service to Bannockburn.

**Hastings.**—The Corporation of Bexhill, the Bexhill Gas and Water Company, and owners, lessees, and occupiers of property and ratepayers in Hastings have given notice to the authorities at the Private Bill Office of the House of Lords that they intend to oppose the company's Bill through its committee stage in the Upper House.

**Lowestoft.**—A letter has been received by the Tramways Committee from Messrs. Hawtayne and Zeden as to the construction of the East Anglian light railways from Lowestoft to Kessingland (the right of which the Corporation has purchased), and the town clerk has been directed to write to that firm and ask the cost of advertising the concession.

**Dundee.**—It is reported that the experiments with top-covers have not turned out a success. The tramway men are agitating for shorter hours. A sum of £1,000 is stated to have been lodged with the Corporation by the promoter of the Broughty Ferry tramway as security for the construction of the line, which is expected to be commenced in three months.

**Manchester.**—It is reported that the motor omnibuses to be used on Manchester suburban routes will be purchased in a few days. Members of the Tramways Committee visited the Olympia show, and it is understood that they saw a suitable type. It is anticipated that these omnibuses will be useful for running in suburban districts, with the object of feeding the tramway system.

**Edinburgh.**—Representatives of the National Electric Construction Company have had an interview with the Linlithgowshire County Council and the Queensferry Town Council in reference to the projected electric tramway from Edinburgh. The company intimated their willingness to also undertake an electric light installation for Queensferry if the authorities consented to the tramway.

**London United Tramways Co.**—Another storm in a teapot occurred at the quarterly meeting of the Ealing Town Council, which has already distinguished itself by a somewhat frivolous attitude towards "those noisy trams." A letter of complaint was received from an inhabitant who offered to contribute towards the cost of proceedings, which were decided upon against the rational advice tendered by Councillor Johnson.

**Erdington.**—It is stated that the Urban District Council, under the power they have acquired, propose to lay a tramway from the bottom of Gravelly-hill to a point just beyond Chester-road, on the main line to Sutton Coldfield. The work will be commenced shortly, and when completed the lines will be leased to the City of Birmingham Tramways Company. The system will be linked up at the bottom of Gravelly-hill to the Aston tramways.

**Yarmouth.**—The arbitration to decide the amount of consideration to be paid by the Yarmouth Corporation to the Yarmouth and Gorleston Tramway Company for the compulsory acquisition of their undertaking was resumed and concluded on Saturday before Mr. Graham Harris. Counsel stated at the opening of the Court that the amount of the valuation of the buildings and land had been agreed at £2,500. Evidence on other matters was then tendered, and the arbitrator will deliver his award "in due course."

**Bath.**—The Light Railway Commissioners held an enquiry last week into an application of the company for sanction to extensions to Newton St. Lo and along Westgate-street. After hearing evidence, the Commissioners decided to disallow the second route, but they will recommend the Board of Trade to grant an order authorising the Newton St. Lo extension, subject to the settlement of clauses for the protection of the County Council. The Commissioners intimated that if the Bath Corporation, who have so far observed a neutral attitude, decide in the future to favour the Westgate-street route, the Commissioners might reconsider their decision. In regard to this route a question of the width of the street was involved.

**London County Council.**—At the meeting of the Stoke Newington Borough Council on Tuesday, the Highways Committee reported the receipt of a lettter from the Shoreditch Borough Council, enclosing a copy of the following resolutions passed by that Council—viz., "(*a*) That the London County Council, the borough councils north of the Thames, and the North Metropolitan Tramway Company be requested to consider the possibility of adopting a system of automobile tramcars driven by petrol or other engines, with a view to avoiding the heavy expense and immense public inconvenience and loss which will be caused by the construction of a conduit or overhead electrical system; (*b*) that the London County Council be requested to arrange with the North Metropolitan Tramway Company for the trial of an experimental petrol or other motor tramcar concurrently with the horse trams"—and asking this Council to similarly approach the London County Council on the matter. The committee recommended the Council to accede to the request. The Hampstead Borough Council have also approved of this suggestion.

**North London Railway.**—Presiding at the half-yearly meeting of this company last week, Lord Rathmore said that there were several features in connection with the working of their line which made comparison in the matter of electrification with other lines impossible. In the first instance, the North London was free from the atmospheric conditions which had conduced to the electrification of other railways; then their railway had a considerable amount of mineral and goods traffic, whilst the other lines with which comparison had been made had to deal with passenger traffic only. Many of the trains on the North London ran over lines of other railways, and until those companies adopted some uniform system of electrification it would be useless for the North London to electrify its line. Science had not spoken its last word on the subject of the most economical manner of applying electricity to traction purposes, and from time to time great advances were being made. The electrification of their line would entail an enormous expenditure of money, irrespective of the abandonment of the present rolling-stock, the loss from which had been estimated at half a million sterling.

**Glasgow.**—On Tuesday Lord Balfour of Burleigh heard arguments in regard to the exercise by the Corporation of running powers over a mile of track belonging to the Paisley Company. A short time ago his Lordship issued an award, but the parties were not agreed upon the interpretation of it, in so far as concerned the question of the cost of the electrical energy for the running of the cars. Tuesday's proceedings, which were held in private, were for the purpose of ascertaining his Lordship's determination as to whether the Corporation, in addition to their other working expenses, were to be allowed a sum to cover the cost of the electrical energy. Lord Balfour intimated that while he could not make any addition to the award in fixing the working expenses, which he previously allowed to the Corporation, he had intended that to those expenses should be added a sum to cover electrical energy. The committee in charge of the tramways provisional order have issued a circular letter letter to the 23 objecting petitioners intimating the abandonment of Clause 82 of the order, which asked that the tramways should be assessed on only one-fourth of their value. This step has been taken in view of the proposal of the Government, intimated in the King's Speech, to amend the law of procedure in making valuations.

**Sunderland.**—The estimated income of the tramways for the year ending March 31, 1905, is £65,003, and the gross expenditure £40,481. 12s. 5d., leaving a gross profit of £24 521. 0s. 7d. It is proposed to dispose of this as follows: reserve fund for accidents, etc., £500; alterations to overhead equipment, £58. 11s. 2d.; new machine tools, £62; interest, £9,357; depreciation and renewals fund (including sinking fund), £14,542 9s 5d. Compared with last year there is an increased revenue of £1,934. The cost of energy is put at £13,300, being an increase of £1,000, due to the East-end route. There is an increase of £700 for interest, and wages also represent an enlarged disbursement. The increase of £1,000 in the depreciation and renewal funds is due to a great extent to the East-end route. Out of the renewal fund the committee are paying for the new offices at the rate of £1.000 a year. The net loss on the East-end route was £950. At Tuesday's meeting of the committee this statement was unanimously adopted. It was pointed out that the working expenses for the year would be about 6·399d. The estimate for the year ending March, 1906. which was also submitted, showed an estimated net profit of £2,090, the receipts being put at £65,500, and expenditure £63 410. The amount put down for power is £12,031, the working expenses being estimated at £38,910 altogether, which is £1,571 less than this year, and £2,592 more than last, while for the compensation reserve fund £400 is set aside; for interest, £9,500; and for depreciation and renewals fund (including sinking fund), £14,600. This estimate was also agreed to.

**Birmingham.**—At a meeting of the Tramways Committee on Wednesday, the scheme for the city, which has been approved by the Council, was further considered in the light of suggestions and petitions presented for slight modification of it. In deference to a petition received from the Homœopathic Hospital it was decided to withdraw the Easy-row line, and the committee also consented to reduce the line in Monument-road between Icknield Port-road and Great Tindal-street from a double to a single track. Mr. Baker, the manager, is to make representations to the Board of Trade on the new regulations prohibiting top-covers on lines with a 3ft. 6in. or less gauge. The Small Heath route, leased to the City of Birmingham Tramways Company, was inspected by Colonel Druitt last week on behalf of the Board of Trade, the work of electrification having been completed. The inspector expressed himself as perfectly satisfied with the arrangements, and not only gave verbal consent for the electric service to run, but allowed a speed of 12 miles an hour between the corner of Moat-row and Small Heath and Yardley. The company approached the Tramway Committee some time ago, and it was ultimately agreed that the Corporation should relay the tramways and bond the rails, the

Digitized by Google

company paying interest on the cost at the rate of 15 per cent. per annum until the expiration of their lease. The company on their part undertook to provide the electrical equipment and the cars. Various clauses were inserted in the agreement with regard to the purchase of the overhead apparatus and feeders at the conclusion of the lease, and also with regard to inter-running from the city to Yardley, and *vice versa*. It was one of the conditions of the agreement that the work of reconstructing the permanent way should be proceeded with as quickly as possible. The agreement was approved by the City Council at a special meeting on May 31 last year, and the reconstruction of the permanent way was commenced in June by Messrs. Dick, Kerr, and Co., contractors, who undertook to complete the contract in 13 weeks. Notwithstanding the fact that considerable difficulties had to be faced, such as the lowering of the road under Bordesley Bridge, the levelling of the road, and the repaving of it in part with granite setts, in part with wood blocks, the work was actually completed in 12 weeks, but owing to various difficulties there was some delay with the overhead equipment and cars. The major part of the overhead system has been installed on the span-wire system. It is expected that the line will be ready for service in a day or two, when there will be through cars from Station-street to Yardley.

**Australia.**—The *New South Wales Railway Budget* for Jan. 2 contains sundry announcements in connection with the railways and tramways of the Commonwealth. It is stated that arrangements are being made by the Victoria Railway Department to start the construction of the Brighton and St. Kilda electric tramway without delay. The Chief Commissioner has undertaken to start work on the project at once. The legal documents embodying the guarantee of the two local councils interested are being drawn up, but the guarantee is regarded as a mere matter of form, as the enhanced value which will be given to the Crown lands *en route* is expected to more than recoup the capital cost of the tramway. The Finance Committee of the Brighton Town Council recommended that the Council give the necessary guarantee of 4½ per cent., in conjunction with the St. Kilda guarantee, on the cost of the construction of the proposed electric tramway from St. Kilda to Brighton. The Mayor, in proposing that the guarantee be given, explained that the Council was not likely to be called upon to pay anything. If the sale of land at Elwood realised £60,000, as expected, £27,000 of that amount would go to the Board of Land and Works, and £33,000 to the construction of the line. This would cover the guarantee, and extend the line to Brighton Beach. The motion was carried. The traffic returns of the Melbourne Tramway and Omnibus Company for the month of November have been issued. They show that the number of passengers carried was 4,412,385, being 135,564 more than in November, 1903. The receipts were £39,761, being £837 more than in November, 1903. The mileage run was 779,221, being 6,529 less than in November, 1903. From Jan. 1 to Nov. 30 there were 45,963,734 passengers carried, the earnings were £414,328, and the train mileage run 8,482,846. For the five months ended Nov. 30, 1903, the revenue totalled £1,253,039; for the five months ended Nov. 30. 1904, the total was £1,410,167. The expired portion of the current financial year thus shows an increase of no less than £157,128 over the corresponding term of the previous financial year. Figures taken out last year covered the period from July 1 to Dec. 2, for which the revenue amounted to £1,258,881, a decrease of £54,668 over the corresponding portion of 1902. Notwithstanding this deficiency, the last financial year, owing to the heavy harvest, ended the best on record with a total revenue of £3,438,140. As the harvest traffic of the present financial year will start with a handsome credit balance, the year promises to prove as prosperous as 1903-1904, even when considerable allowance is made for the prospective falling off in the grain yield. On the New South Wales loan estimates, which have been passed by Parliament, are the following items in connection with railways and tramways: For railways, £250,000; being £110,000 for rolling-stock, to meet additional traffic requirements; £80,000 for additions to railway lines, buildings, and for other purposes; £50,000 to further improvements of grades; and £10,000 towards the duplication of Penrith Viaduct—further sum. For tramways, £85,000; being £65,000 for additions to lines, workshops, and buildings, and for other purposes, to meet the requirements of traffic; and £30,000 for rolling-stock to meet traffic congestion in certain directions. The following amounts were also voted for the railway and tramway construction: Railways, £282,883; being £18,000 for Narrabri to Walgett, with branch to Collarendabri—further sum; £2,300 for Cobar Mines Railway (Land)—further sum; and £202,583 to recoup City Railway extension and Sydney Central Station votes, on account of the following services charge thereto—viz.: £22,583 for new cemetery, La Perouse—laying-out, re-erection of headstones, and other works; £15,000 for Prince of Wales's Hotel—erection; and £165,000 for surplus lands, Central Station approaches. A sum not exceeding £14,248 for tramway construction—tramways generally—to recoup City Railway extension and Sydney Central Station votes—tramways into Central Station. The South Australian Government, it is reported, intend to lose no time in seeking to put into operation the Tramways Act passed during last session. Preliminary arrangements are being made to secure the option over all existing tramway companies as provided by the new law, and at the earliest possible date the Government will invite tenders for taking over the lines and converting them to electric traction in terms of the Act. Ministers are sanguine that satisfactory tenders will be forthcoming, and in this view they are supported by the Adelaide representatives of more than one company interested in such undertakings. Enquiries have been made by several electric traction firms, and copies of the Act forwarded to the head offices in order to facilitate the preparation of tenders. The tramways companies of this State are in receipt of a letter from the Government which is the outcome of conferences that have taken place between the Premier and the solicitor for the companies. The Government invite the companies to confer and agree upon a price they are prepared to accept for their properties. If the amount should be what the Government consider reasonable, the expense and delay that would be caused by arbitration may be avoided. It is understood that the directors of the various companies will meet at an early date and agree to act together in the negotiations with the Government. As soon as the option of purchase has been secured at a price agreed upon, the Government intend to call for tenders.

## LIGHTING AND GENERAL.

**Bath.**—The City Council will apply for a loan of £10,000 for electric supply extensions.

**Dundee.**—No arrangement has yet been made with regard to the site for the new electric power station.

**Bishop's Stortford.**—The Urban District Council are still discussing the transfer of their electric lighting order.

**Grantham.**—An electrical exhibition, promoted by the Urban Electric Supply Company, is being held in the Wharf-road hall.

**Leith.**—The estimates for plant in connection with the extension of the electric lighting station have been remitted to the engineer for report.

**Southmolton.**—The District Council have sanctioned the overhead telegraph extension to Rackenford, subject to the approval of their surveyor.

**Edinburgh.**—The number of lamps applied for from Jan. 20 to Feb. 9 was as follows: lighting, 1,758; power, 1,425; and heating, 408—in all, 3,591 of 8 c.p.

**Bradford.**—An expert is to be appointed to report in connection with the proposed extensions estimated to cost from £35,000 to £40,000, and on the plant generally.

**Plymouth.**—The Corporation have reduced the charge for power from 3½d. to 2d., and have made other concessions to the users of current for power purposes.

**Galashiels.**—The Town Council have resolved that an agreement be entered into with a company to carry out the installation and supplying of electric light to the town.

**Southend.**—The gross profits on the Corporation electric light undertaking last year were £3,806. After meeting interest and instalment charges, £358 was devoted to the relief of the rates.

**Calcutta Electric Supply Co.**—The number of units delivered to consumers during the four weeks ending Jan. 27, 1905, was 199,288, compared with 124,324 in the corresponding four weeks of the preceding year.

**Western Telegraph Co.**—The directors have declared an interim dividend, payable on March 25, of 3s. per share, or at the rate of 6 per cent. per annum (free of income tax) for the quarter ended Dec. 31, 1904.

**Sir John Cass Technical Institute.**—The Science Students' Association paid a visit on Saturday to the works of the Metropolitan Electric Supply Company at Willesden. Messrs. Hayes and Bedbrooke conducted the party.

**Swinton.**—The Swinton and Pendlebury District Council intend to apply for sanction to a loan of £6,900 for purposes of electricity supply to the district, as to which an agreement was recently concluded with the Lancashire Electric Power Company.

**Parliament.**—Among the Bills read a second time on Tuesday were the Administrative County of London and District Electric Power Company Bill, Alexander Park and Palace Bill, and the East London and Lower Thames Electric Power Bill.

**W. T. Henley's Telegraph Works Co.**—The directors have decided to recommend a dividend for the year ending Dec. 31, 1904, on the ordinary shares of 15 per cent., less income tax, including the interim dividend of 5 per cent. paid Sept. 1 last.

**Stoke Newington.**—Arrangements have been made with the Islington Borough Council for the supply of electrical energy in bulk to enable the Stoke Newington Council to supply current to the premises at the corner of Blackstock and Seven Sisters roads.

**Wainwright Bros.**—We understand that this firm, which have branches at Pritchard-street, Saville-street, and Oxford-street, Manchester, have opened an electrical department in charge of S. B. Wainwright, who has had many years' experience in that direction.

**Sligo.**—We understand that the Corporation have granted the application of Messrs. P. A. M'Hugh, M.P., E. Foley, and J. P. Higgins to erect poles and lay mains in or on the streets and roads in connection with electric lighting and the distribution of electric power in the borough.

**Horsham.**—It has been decided to apply for sanction to borrow £4,500 for electric lighting purposes, to cover £3,100 (cost of new feeders and steam balancer), £400 for free wiring purposes, and £1,000 for the cost of various extensions already carried out, but not included in the previous schemes.

**Portsmouth.**—The Telephone Committee are unable to comply with most of the new applications that are coming in so steadily, and on Wednesday the consulting engineer's (Mr. Bennett) plans and estimates were approved for extensions in town and country, and will be sent to the Local Government Board for sanction.

**Paddington.**—An electrical exhibition which is being organised by the Metropolitan Electric Supply Company at the Queen's-road Baths, Bayswater, we are informed, has met with a most gratifying response from the electrical trade, and that practically the whole of the space has already been allotted. Attractiveness as well as instruction is the motto.

**Dalkeith.**—The Electric Supply Corporation, Limited, have asked the Council to substitute a definite schedule of hours for lighting and putting out the lamps, and to calculate the amount of electricity consumed from

Digitized by Google

that schedule, instead of by meter. The Council declined to accede to the request, and arrangements are being made to fit meters for the street lamps.

**Bournemouth.**—The following members of the Council have been appointed a committee to consider and report upon all matters which were referred to the Telephone Committee, dissolved by the Council on Dec. 6 last: Aldermen Abbott, Burden, Lawson, Parsons; Councillors Banks, Elcock, Evans, Hawkes, W. E. Hutchins, Minty, Jolliffe Wilson, and Youngman.

**Wimborne.**—The Bournemouth and Poole Electricity Supply Company have informed the Council that they do not intend to place any overhead wires in connection with the proposed supply of electricity in Wimborne and district. The Council had previously decided to withhold their consent because they were under the impression that the company intended to do so.

**Barnstaple.**—The mayor's financial statement in regard to working the municipal electrical undertaking for the year ending Jan. 28. 1905, shows a total expenditure of £1,958. The income, including £128 shares in hand, was £3 540. This gives a surplus of £1,582, from which must be deducted £1,290 interest on mortgage debt and repayment of principal, leaving a net surplus of £291.

**East London and Lower Thames Electric Power Bill.**—This Bill has passed Mr. Campion, senior examiner of Standing Orders. It provides for the incorporation of a company with a capital of £2,200,000 to supply electrical energy throughout Hackney, Bethnal Green, Stepney, Poplar, Deptford, Woolwich, Greenwich, and Bermondsey, the county borough of West Ham, and a large part of the county of Essex.

**Lowestoft.**—There are now connected to the mains 578 consumers representing 29,903 8-c.p. lamps. During January five new consumers were connected representing 708 8-c.p. lamps. The agreement with the railway company with reference to the new cables under the harbour (which is almost similar to the existing agreement) has been approved by the Town Council, subject to the approval of the engineer.

**Hammersmith.**—The last report of the Electricity and Lighting Committee shows that the premises of 16 additional consumers, representing a maximum of 865 8-c.p. lamps, have been connected to the mains; that 12 consumers have been disconnected; and that the present number of consumers taking current from the mains is 1 541. Advertisements are to be issued inviting tenders for the erection of the boiler-house extension, so soon as the quantities are ready.

**Keighley.**—New plant is required at the electricity works at a cost of £4,480, as the present plant is not sufficient reserve in case of a breakdown. The output of the works during the current year will, it is estimated, amount to 350,000 units, and the proposed new plant would give an increased generating power of 200 kw., and would increase the revenue-earning capacity of the works by 45 per cent., while the capital charges would be increased by only about 22 per cent.

**Walsall.**—The Electricity Committee's annual statement of accounts shows a net profit, after payment of interest and sinking fund, of £1,060, as compared with £313 in the previous year. This sum is to be carried to the reserve fund. This is a very satisfactory result, seeing that the price of current had been reduced from 6d. to 4d. per unit to the public and from 2d. to 1½d. to the tramway undertaking. Electric mains are to be extended at a total estimated cost of £1,855.

**Stock Exchange.**—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Baker-street and Waterloo Railway Company's scrip certificates to bearer (fully and partly paid) for £500,000 4 per cent. perpetual debenture stock. The committee has also been asked to allow Metropolitan District Railway Company's further issue of £200 000 4 per cent. perpetual debenture stock, 1903, to be quoted in the official list.

**Devonport.**—The Electric Power Committee have decided to instal electricity in the free public library at a cost of £84, and also to allow a sub-committee to deal with the question of extending the main to Argaum Villas, Stoke, and with the application from the Admiralty for an estimate of the cost of lighting the eastern part of the Royal Albert Hospital. The Local Government Board have declined to allow repayment of the loan recently sanctioned for extending the electricity works to cover a longer period than 21 years.

**St. Marylebone.**—The Chairman of the Finance Committee was asked from what fund the interest on the electric light loan would be paid, or whether it was suggested that they should have a suspense account; also why there was no statement of the amount of money which would have to be provided by the Council when it took up the Bill. Councillor Leaf, in reply, said the question of the interest on the Bills would come up under the Finance Committee's estimate next fortnight. The auditor would decided the legality of the payment.

**Dartmouth.**—Elaborate arrangements are being made for the electrical exhibition to which we referred in a previous issue. We note that electricity is well supported considering the size of the town, which has only 6 579 inhabitants. In the first three months 2 400 8-c.p. lamps were connected with the mains, and since then they increased to Dec. 31 last to 10,305. The power used aggregates to 35 h.p., being used for drawing railway trucks to coal ships, and driving wood-working, forge-blowing, organ-blowing, pumping, and engineering machinery.

**Mansfield.**—Extra staff will be needed at the works when the tramways supply commences. The charges from March 31 will be as follows: For lighting—7d. per unit for any quantity of electrical energy used during each quarter not exceeding the equivalent of 100 hours of supply at the maximum demand, and 1d. per unit for any quantity used during each quarter in excess of the above. For power—4d. per unit for any quantity of electrical energy used during each quarter not exceeding the equivalent of 100 hours of supply at the maximum demand, 1d. per unit for any quantity used during each quarter in excess of the above.

**Ealing.**—The account for the nine months ending December shows a profit despite the reduction of 1d. per unit in price charged. The Hanwell District Council have asked whether the Ealing Town Council would be willing to supply Hanwell with current, and, if so, on what terms? Further consideration of the letter has been deferred. The Council have decided to join the Shoreditch and Hampstead combinations for the purpose of jointly opposing the Administrative County of London and the Metropolitan Electric Supply Company's (Various Powers) Bills respectively.

**Cleckheaton.**—From the last accounts of the electric lighting and refuse destructor works, it appears that £22 653 has been borrowed and £24.600 expended on the former account, but that on the latter account (for which £7.560 had been authorised) there remains an unexpended balance of £1,936. A sum of £1,600 has been transferred from the destructor to the electricity loan account. The electricity revenue account shows expenditure £4,331, income £3 531, loss £800. The chairman of the committee and the electrical engineer have been requested to present a report to the next meeting on a revision of charges for current.

**Walton-on-Thames.**—The Walton Ward Committee have elected Mr. Miskin as chairman. The ward committees, at the last Urban District Council meeting, recommended, after correspondence with the Edmundson's Electricity Corporation, that one arc lamp be erected in each ward, and that the remainder of the free power for the current year be taken in Nernst lamps. It was left to the Walton and Hersham Ward Committees to decide as to the position and power of their share of the lamps, according to rateable value. After discussion the substitution of Nernst for the proposed arc lamps was agreed to, and the report, thus amended, was approved.

**Aberdeen.**—Mr. J. B. Hegarty, postmaster, presided on Saturday evening at the annual presentation of prizes under the auspices of the Aberdeen branch of the Telegraph Messengers' Institute, at which there was a large attendance of the lads and their parents and friends. Bailie Eeslemont, in presenting the awards to the boys, said there were about 100 messengers employed in the telegraph department at Aberdeen. Last year the number of ordinary telegrams delivered amounted to 554,194; and, in addition to that, there were 125 758 Press messages, making a grand total of 679,772. A competition in drill took place in the course of the evening, and the judge, Lieutenant Robertson, V.C., awarded the prize to E team.—*The Scotsman.*

**Chester.**—The Chester electrical engineer has presented a report to his committee on the subject of public lighting in the city. The following epitome has appeared in the *Chester Chronicle*: "The increased cost of public lighting by electricity as compared with gas is due to the improved lighting of the thoroughfares. In practically every case where gas has given place to electric lighting, either arc lamps are erected in place of two or three gas lamps, or more incandescent electric lamps have been erected in place of the gas lamp abolished. Since March, 1903, 57 arc and 115 incandescent electric lamps have been erected at an annual cost of £800, as compared with 110 gas lamps disconnected, at an annual cost of £330, being an increased expenditure (in about two years) of £470. When it is realised that the aggregate candle-power of these electric lamps is about 38,340, and costs about 4·94d. per candle-power per annum as compared with the gas lamps giving about 2,920 c.p. at about 28·08d. per candle power per annum, it hardly appears possible that there can be two opinions as to whether the citizens get value for the cost of the additional lighting. The charges for public electric lamps are based on each lamp burning 3,644 hours per annum—viz., each open type arc burning all night £19, each open type burning half-night £10, each enclosed arc burning all night £13. 10s., each enclosed arc burning half-night £8, each 16 c.p. incandescent £2. 17s. 9d., and for public 4ft. gas burner on the same basis per annum £2 14s. 6d. The charges per candle-power per annum for the different kinds of lamps are—(1) electric: 1,000-c.p. arc lamps 4·56d., 600 c.p. arc lamps 5·4d., 70-c.p. Nernst lamps 19 8d., 16-c.p. incandescent 43·3d.; (2) Gas: 13-c.p. (4ft.) burner 50·3d. It may interest the committee to know that recently the Manchester Corporation went very deeply into the question of public lighting by the most modern and improved systems of gas and electricity, and in each instance electricity came out cheapest. Another valuable and interesting report is that of the city surveyor of Westminster. There are 1,105 electric lamps and 2,076 gas lamps on the thoroughfares of Westminster, and the lighting by electricity is considerably cheaper than by gas. The average income per unit supplied to public lamps for the year ending March, 1904, is 1·753d., as compared with private consumers 3·9d., and tramways 1·75d. Comparing the public lighting accounts (gas and electric together) for the last nine months with the corresponding period of last year, there is an increased expenditure of £208 18s. There are a number of circuits which do not contain the full number of lamps, and in consequence of resistances which have to be used there is a waste of energy; these circuits might be completed with advantage to the public lighting and the electricity department, at no very considerable cost, as there are a few lamp columns and accessories on hand which are quite suitable for the purpose."

**Bexhill.**—An electrical exhibition is now being held at the Kursaal by the Borough Council, and will remain open until Saturday. A very special feature is being made of electric heating and cooking. An electric kitchen is fitted up, and lunches and dinners are being prepared and served daily at popular prices. The Council is arranging to hire out the various cooking utensils, and, we are informed that, judging by the interest taken by the public in the electric kitchen, this move promises to substantially increase the day load. A number of engineers from neighbouring towns visited the exhibition yesterday,

Digitized by Google

and were entertained by the Mayor Earl de la Warr) at an electrically-cooked luncheon. During the time of the exhibition the Kursaal is being lighted at intervals and alternately by incandescent lamps, arc lamps, and Nernst lamps, thus illustrating the different systems of electric lighting. Demonstrations of the power of electric searchlights across the channel take place every night and attract large numbers.

**Richmond.**—It appears that at the interview of the deputation with the Postmaster-General, Councillor Chancellor pointed out that, although the amenities of the borough had been preserved from being spoiled by the erection of telegraph and telephone poles, it had only been done at an expense of £120, and that it was hoped that, having regard to the large expense incurred in preserving the view from Richmond Hill, and the particular amenities of the borough, the Postmaster-General would avoid sanctioning the erection of poles in this unique suburban district, and that all necessary wires would be placed underground without expense to the borough. The Postmaster-General assured the deputation that he would do his best to facilitate the preservation of places of natural beauty where this could be done by taking a longer route for the wires, but it was impossible to place long trunk telephone wires underground, as their efficiency would thereby be destroyed. He also promised to carefully consider any representations made to him.

**London Gazette.**—The partnership between Howard Marryat and Harry Alexander Place, carrying on business as electrical engineers at 28, Hatton-garden, London, E.C., has been dissolved by mutual consent. The partnership between George Edward Vint and Maurice Edgar Moss Vint, carrying on business as electrical engineers at 92, Rusholme-road, Manchester, has been dissolved. The partnership between John Boutch and Colin Bell Heaviside, electrical and mechanical engineers, Neville-street, Newcastle-on-Tyne, has been dissolved by mutal consent. A first and final dividend of 4½d. in the £ has been declared in the estate of Thomas Williams, electrical engineer, 54, Bridge-street, Llandaff, Glamorgan. Arthur Francis Whinney (with a committee of inspection), 32, Old Jewry, London, E.C., has been appointed liquidator in the estate of the Sir Hiram Maxim Electrical and Engineering Company, Limited, 44, Gillingham-street, Westminster. The partnership between George Brearley, Joseph Horrox, and James Bertram Horrox, carrying on business as mechanical and electrical engineers at 90, Back George-street, Manchester, has been dissolved by mutual consent.

**Kingston.**—Councillor Francis, in moving the approval of the Lighting Committee's minutes at the last Town Council meeting, referred to the working of the change in the method of charging for the light, which took effect just about a year ago. He said it was estimated that the alteration would cost them the first year some £700, and, as a matter of fact, they had received £650 less from their old customers, which was a very close estimate, upon which the engineer was to be congratulated. The undertaking had shown a very good expansion, and the money so lost had been made good by the increased number of units sold. But it had to be borne in mind that there were larger capital charges to face this year, and he did not wish to convey the idea that the whole of that additional receipt was in the nature of increased profit. Councillor Sprunt said most of the £650 they had lost had gone to benefit their good customers, and what the committee hoped for was actually happening—they were greatly increasing their use of the light. Private houses in the town were now getting their light at 4½d. per unit instead of 6d. as formerly.

**Surbiton.**—The following details of the position of affairs in regard to the electric lighting undertaking were laid before the last District Council meeting: "On Oct. 31 last it was found necessary for the first time to run both the 100-kw. engines which comprise the first plant, and after that date they were run together each night, excepting on Sundays and Wednesdays. The new 220-kw. plant was installed early in December, and put into permanent work on the 20th of that month, and it had taken the load every night since then. The highest load recorded was 138 kw. The full capacity of the station, allowing for the possibility of the failure of any one of the engines, was 220 kw., and it might, therefore, be considered that there was at present a margin in hand of 80 kw. The total number of lamps now fixed was 13,000 of 8 c.p., and it was estimated that by the end of the year the total would increase to 17,800 lamps, and that the maximum load would then be 180 kw. This margin of 40 kw. would serve for a second winter, but it was certain that an extension of the works would be required by the autumn of 1907. This extension would cost about £7,500. It was evident that if a supply was given to the Dittons the enlargement of the plant would, in all probability, become necessary 12 months sooner."

**West Ham.**—The expenditure of the electricity department during the year ended March, 1904, amounted to £83,342, chiefly upon the completion of the new generating station buildings and equipment at Canning Town. This made the total capital expenditure £268,511. The tramways took 23,740 units. The net result of the year's working is a deficiency of £3,788, partly owing to the disorganisation of the supply while the transfer to the new station was made. The expenses of generation, distribution, public lamps, rents, management, etc., were £20,647, and the income was £30 364, made up as follows: Energy sold for public lighting, £3,096; private lighting, 1,602,829 units at rates ranging from 7d. to 2d. (over a million at the latter figure), £25,001; power supply, 121 309 units at from 5d. to 1d., £1,514; traction supply, £210; special lighting for artisans' dwellings, £246; received in respect of hire purchase and hire of motors and installations, £183; and sundry other amounts from meter rents and wiring and fittings. The gross profit thus figures at £9,817, and there is a further receipt of £44 in respect of arc lamp columns, making £9,861. On the other side of the net revenue account, however, repayment of loans receives £3,168, interest on loans receives £2,609, and interest (£2,020) is paid on the bank overdraft; also redemption and extinction of stock requires £1,808, and interest on Corporation stock another £4,045, thus making a net deficiency of £3,788, which is carried to the appropriation account. As this fund already had £1,689 to its credit, the deficiency at March 1904, thus became reduced to £2,099. There is a reserve fund from previous years of £1,740.

**Metropolitan Power Bills.**—Reporting on the Electric Power Bills now before Parliament, the Parliamentary Committee of the London County Council stated on Tuesday that in their opinion the proposals in respect of which powers were sought were such as to constitute a serious menace to existing and future municipal electrical supply undertakings, and they were fully persuaded that the magnitude of the proposals, the overlapping powers sought, and the general reversal of the conditions now applying to London, left the Council no alternative but to oppose the Bills. Whilst the object aimed at by the promoters of the two new companies might not be to establish a monopoly, it must inevitably result in this, and the existing companies had introduced Bills, mainly, it would appear, in self-defence. It was obvious that a supply of electricity for power purposes and also for the lighting of premises supplied with power could leave in the hands of the existing authorities the residue of the custom only. They proposed reporting further on the matter at a later date, and in the meantime petitions on behalf of the Council were being presented against the Bills. The committee, after reviewing the circumstances existing at present in London under the Electric Lighting Acts and the Council's action in connection with the matter, state that they desire to direct special attention to the general principle to which the Bills seek to give effect—viz that in the opinion of the promoters, electrical energy can be more economically produced and transmitted by means of a large undertaking supplying over a much wider area than was perhaps thought necessary when the Electric Lighting Acts of 1882 and 1888 were passed, and on the faith of which enormous capital has been expended. This view has already been adopted by the Westminster and St. James's Companies and also by the Kensington and Notting Hill Companies, which take a large portion of their supplies from two stations established to supply in each case two companies. Out of many suggestions which they have considered, they say that the three most practicable seem to be—(*a*) that such companies as supply in bulk should be placed on a sliding scale of price and dividend, and that powers of purchase be given to the Council with regard to these on lines similar to those laid down by the Electric Lighting Acts, (*b*) that the Council itself should be the authority for generating electricity in bulk in London; or (*c*) that some arrangement should be arrived at between the existing companies, satisfactory to the Council and the borough councils, with the object of securing a supply of electricity to London consumers upon the most economical basis. They recommended that the action taken by the Parliamentary Committee, as explained in the above report, in connection with the Supply and Power Bills introduced into Parliament in the session of 1905, be approved. The Council postponed discussion of the report, and the same will be brought up for discussion again on Feb. 28. Practically each of the eight London Bills is opposing all the others. There are over 100 petitions against the Administrative County of London and District Electric Power Company's measure, among the petitioners being the Metropolitan Water Board and the City Corporation. A further six petitions have been lodged against the Bill of the Central Electric Supply Company, among the petitioners being the City Corporation and the London County Council. The County of London Electric Supply Bill will be opposed by the Metropolitan Water Board, the City Corporation, the London County Council, and others. Thirteen further petitions have now been lodged against the East London and Lower Thames Electric Power Bill. The Metropolitan Electric Supply Company's (Various Powers) Bill is to be opposed by the County of London Electric Supply Company, the London County Council, St. James's and Pall Mall Electric Supply Company, and others. Against the North Metropolitan Electric Power Supply Bill a further batch of 12 petitions has been received.

## PROVISIONAL PATENTS, 1905.

FEB. 13.

**2888. An improvement in electrical trolley heads with wire-finding apparatus attached.** John Thomas Cherry and Edward Henry Clive, 2, Bedford-park, Plymouth.

**2890. Improvements in apparatus for electrically operating gas-valves.** Herbert Scott, Marchfield, Wilmer-drive, Bradford.

**2894. An improved electric lampholder with locking device to prevent the withdrawal of a lamp therefrom.** Hugo Hirst and Henry Bevis, 71, Queen Victoria-street, London.

**2908. Improvements in and relating to telephone switch-board connections.** Robert McLean, Telephone House, Brock-road, St. Sampson's, Guernsey.

**2918. Improvements in and relating to dynamos and the like.** Charles Anthony Vandervell and William Henry Wardon Proctor, 1, Queen Victoria-street, London.

**2919. Improvements in and relating to devices for controlling electric currents.** Claude William Atkinson, 1, Queen Victoria-street, London.

**2920. Improvements in electric switches and resistances.** Edmund Garside, 1, Queen Victoria-street, London.

**2934. Improvements in temperature compensating device for therme-electric measuring instruments.** William Henry Bristol, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

Digitized by Google

**2939. Improvements in electric incandescence lamp fittings.** Frank West Suter, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**2940. Improvements in electric switches.** David Garbutt Pinkney and Howard Melville Rootham, 82, Mark-lane, London.

**2944. Improvements in and relating to transformers.** Oswaldo de Faria, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Feb. 20, 1904, being date of application in France.) (Complete specification.)

**2980. An electric light maximum demand alarm relay.** George Octavius Wills, 502, Romford-road, Forest Gate, London. (Complete specification.)

**2982. Improvements in line selectors for telephones and like systems.** Paul Hardegen, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

FEB 14.

**2998. Improved ironing machine with electrically-controlled pressure.** Albert Ernest Hacking and John Pycroft, 11, Burlington-chambers, New-street, Birmingham.

**3009. Improvements in electrical tramway conduit systems.** Aubrey Llewellyn Coventry Fell and John Hall Rider, 303, Camberwell New-road, London.

**3029. An improved electrical insulating material.** Joseph Devonport Finney Andrews, 2, Park-avenue, East Sheen, London.

**3047. Automatic electric early morning waiter.** George James Gray, 151, Capstone-road, Bournemouth.

**3049. Combined electric coupling and two-way plug.** Harold Stokes, 25, Ringmer-avenue, Fulham, London.

**3076. Improvements in electric signalling apparatus.** Evershed and Vignoles, Limited, and Sydney Evershed, 1, Queen Victoria-street, London.

**3078. Improvements in lightning arresters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**3081. Improvements in protective devices for electric circuits.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**3088. Improvements in combined switches and fuses.** Arthur John Fuller, 13, Chipstead-street, Fulham, London.

FEB. 15.

**3125. Improvements in or relating to electric motor starters.** Frederick John Jones, 104, Colmore-row, Birmingham.

**3129. An improved lifeguard for electric tramway cars and similar vehicles.** Samuel Robert Cameron, 22, Withington-street, Cheetham Hill, Manchester.

**3155. Improvements in dynamo-electric machines and motors.** Wilfrid Robert Vernet Marshall, Torrieburn, Barnes, Surrey.

**3157. Improvements in the construction of dynamo-electric machines and electric motors.** Edmund Scott Gustave Rees, Prince's-chambers, Wolverhampton.

**3166. An improved X-ray tube for use with alternate or unidirectional currents.** Alfred Charles Cossor, 54, Farringdon-road, London.

**3171. Improvements in and relating to electric motors and dynamo-electric machines.** Vickers, Sons, and Maxim, Limited, and Alfred David Williamson, 7, Southampton-buildings, Chancery-lane, London.

**3177. Improvements in or relating to the control of electric motors.** William Geipel and Frederick Montague Townsend Lange, 46, Lincoln's-inn-fields, London. (Complete specification.)

**3183. Automatic regulating apparatus for electrical installations with variable current consumption, worked by dynamos and accumulator batteries.** Emil Dick, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**3184. Improvements in installations for controlling electrically-propelled trains.** Siemens Bros. and Co., Limited, and Charles Frewen Jenkin, Birkbeck Bank-chambers, Southampton buildings, Chancery-lane, London. (Complete specification.)

**3189. Improvements in and relating to dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (The General Electric Company, United States.)

**3195. Improvements in or relating to apparatus for controlling electric motors.** John Martin Barr, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act 1901, March 7, 1904 being date of application in United States.) (Complete specification.)

**3196. Improvements in controllers for electric motors.** Thomas Steel-Perkins, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, March 7, 1904, being date of application in United States.) (Complete specification.)

**3201. Improvements in central-station telephone systems working with a common battery.** Isidore Bernard Birnbaum and Francis George Bell, 322, High Holborn, London.

FEB. 16.

**700A. Improvements in apparatus for use in wireless telegraphy.** Hermann Heinicke, 3, Upper Vernon-street, London. (Date applied for under Patents Rule 9, Jan. 13, 1905.) (Complete specification.)

**3250. Improvements in and relating to electric arc lamps.** Hugo Bruckmann, 81 High Holborn, London.

**3265. Improvements in electrical switches.** Edward Tyer, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**3280. Devices for exerting an electromagnetic influence upon the arcs of electric arc lamps.** Tito Livio Carbone, 322, High Holborn, London. (Complete specification.)

**3283. Improvements in electrical sound-producing apparatus.** Albert Charles Marie Legendre, 70, Chancery-lane, London. (Date applied for under Patents Act, 1901, Sept. 24, 1904, being date of application in France. (Complete specification.)

**3289. Improvements in electric heaters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**3291. Improvements in electric control apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

FEB. 17.

**3293. Improvements in electric traction on a shallow-conduit system.** Samuel Green Bennett, Clyde House, Heath Town, Wolverhampton.

**3312. Electric self-acting apparatus for tightening ropes and the like.** Heinrich Otto Adam, 57, Barton-arcade, Manchester. (Date applied for under Patents Act, 1901, Feb. 18, 1904, being date of application in Germany.) (Complete specification.)

**3313. Improvements in or relating to wireless telegraphy receivers.** Francis Patrick Reid, 37, West Nile-street, Glasgow.

**3327. Improvements in electrolytic meters.** George Hookham and Sydney Holmwood Holden, 18, Southampton-buildings, Chancery-lane, London.

**3346. Method of, and apparatus for, electrically oxidising atmospheric nitrogen.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (Demetrio Helbig, Italy.)

**3347. Improvements in switch apparatus for coin-freed electricity meters.** John Meany Tourtel, 146A, Queen Victoria-street, London.

**3356. Improvements in automatic electrical cut-outs.** Charles Anthony Vandervell and William Hodgson, 1, Queen Victoria-street, London.

**3357. Improvements in and relating to means for driving dynamos and the like.** Charles Anthony Vandervell and William Hodgson, 1 Queen Victoria-street, London.

**3360. Improvements relating to sight magnetic compasses.** Arthur Fred Collins Bentley, 8, Quality-court, Chancery-lane, London.

**3371. Improvements in mechanism for actuating electrical clocks.** Gustav Schonberg, 1, Great James-street, Bedford-row, London. (Complete specification.)

**3372. Improvements relating to casings for electric switches and fuses.** Frederick Hagger Headley, 322, High Holborn, London.

FEB. 18.

**3392. Improvements connected with trolley wires of overhead electric tramways systems.** George John Conaty and Harry Hartley, 128, Colmore-row, Birmingham.

**3394. Improvements relating to electric ignition apparatus for internal-combustion motors and for like purposes.** Timothy Morris, 18, Southampton-buildings, Chancery-lane, London.

**3401 Improvements in and relating to resistances for electric current.** Robert Hopfelt, 10, Friedrichstrasse, Berlin, Germany. (Complete specification.)

**3409. Improvements in the arrangement of multiple switch-boards for telephone exchanges.** Siemens Bros. and Co., Limited, Queen Anne's-chambers, Broadway, Westminster, London. (Siemens und Halske, Akt.-Ges., Germany.) (Complete specification.)

**3424. Improvements in belt tension regulators.** The British Thomson-Houston Company, Limited, 83. Cannon-street, London. (The General Electric Company, United States.)

**3431. Improvements in and relating to electrolytic meters.** Claude William Atkinson, 1, Queen Victoria street, London.

**3432. Improvements in electric machineries.** The Company "Sachsenwerk Lichtund Kraft-Akt.-Ges.," 1, Queen Victoria-street, London. (Date applied for under Patents Act, 1901, Feb. 20, 1904, being date of application in Germany.) (Complete specification.)

**3433 Improvements in devices for exerting an electromagnetic influence on the arcs of electric arc lamps.** Tito Livio Carbone, 322, High Holborn, London. (Complete specification.)

**3442. Improvements in and relating to gloves for electric insulation purposes.** Karl Weilbier, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published March 9.*

1904.

**3637. Dynamos.** Lapeyrade. (Date applied for under International Convention, Feb. 10, 1903.)

**3356. Electric and other lifts and hoists.** Chaudoir.

**3523. Hand telephones.** Friedlaender.

**3826. Manufacture of insulating or non-conducting materials for electrical purposes.** Pontite, Limited, and de Pont.

**3885. Electrical switching systems.** Wright and Nicholls. (Date applied for under International Convention, Feb. 16, 1903.)

**4110. Electrical connectors.** Martin and Lowson.

**4943. Electric controllers for use with cranes, winches, transporters, and similar or other machinery.** Cleveland Bridge and Engineering Company, Limited, and Hill.

**5926. Electric motors.** Mavor and Coulson, Limited, and Mavor.

**6040. Electric arc lamps.** Levis. (General Electric Company).

**6041. Electric arc lamps.** Levis. (General Electric Company.)

**6042. Electric arc lamps.** Levis. (General Electric Company.)

**6617. Controlling devices for electric motors.** Marples.

**7062. Electric arc lamps.** Carolan. (General Electric Company.)

**7985. Attachments for electric incandescent lamps.** D'Olier, junior.

**8096. Means or device for catching and supporting overhead electric cables or wires when fractured.** Denton-Ingham and Jones.

**8399. Alternating electric current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**8402. Alternating electric current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**8590. Brush-holders for dynamo-electric machines.** British Thomson-Houston Company, Limited. (General Electric Company.)

**8699. Windings for dynamo-electric machines, and methods of and apparatus for forming the same.** British Thomson-Houston Company, Limited. (General Electric Company.)

**8777. Attachment of globes or shades to electric lamp fittings.** Williams-Thomas and Northwood.

**9427. Automatic electromagnetic sanding gear for use on electric railways and tramways operated instantaneously with the electric brake from the controller handle.** Crosbie and Ward.

**10356. Construction of mounting of trolley arms for collecting electric energy from overhead cables for electric traction.** Phillips and Parkin.

**13928. Automatic electric cut-out mechanism.** Jones. (Long Arm System Company.)

**19126. Dynamo-electric machines.** Foot. (Date applied for under International Convention, Sept. 16, 1903.)

**20953. Electric igniter for simultaneously igniting and simultaneously or successively extinguishing gas burners.** Candi and Candi.

**21601. Trolley sheaves for engaging electric power wires, applicable also to sheaves and guide pulleys used with wire ropes, cables, and the like.** Williams.

**26499. Electric motor-controlling systems.** Eastwood.

**27185. Electric couplings.** Sorg.

**27538. Means for transforming direct electric current into multiphase alternating current.** Steinmetz. (Date applied for under International Convention, Dec. 17, 1903.)

**27860. Forming tank for accumulator elements.** Gardiner.

**28155. Dynamo-electric machines.** Phœnix Dynamo Manufacturing Company, Limited, Pohl, and Pohl.

**28156. Construction and ventilation of field coils of dynamo-electric machinery.** Phœnix Dynamo Manufacturing Company, Limited, and Pohl.

**28369. Electric switches.** Harrison. (Guett.)

**28852. Conduit for containing electric cables and wires and other wires, tubes, pipes, and the like.** Hepworth-Collins.

**28875. Electric coupling for use in lamp fittings.** Simmonds.

**29061. Electric railway conduit systems.** Van Aerschot.

**29118. Electric insulators and supports therefor.** Fairbanks.

## NOTES.

**Wireless Telegraphy.**—The Marconi Wireless Telegraph Company, Limited, have decided to prepare their own telegraphic code. The company will from time to time issue a register containing the names and telegraphic and business addresses of all people who use the code, for which, together with a copy of the register, a charge of one guinea will be made.

**Radium.**—According to a communication just made to the Academy of Sciences, radium has been found to be a complete antidote to all snake bites. Its emanations totally destroy the venom, and, at the same time, kill all germs contained in it. It is stated, however, to have no effect upon the poison of a reptile described as the "land salamander," or on that of the toad.

**The Telephone Purchase.**—The Select Committee to consider the agreement between the Postmaster-General and the National Telephone Company, and to report whether it is desirable in the public interest that the agreement shall become binding, will consist of Mr. Beckett, Sir Horatio Davies, Mr. Helme, Sir William Holland, Mr. J. Nolan, Sir Charles Renshaw, and Mr. Stuart Wortley.

**Olympia Motor Show.**—The Society of Motor Manufacturers and Traders have decided to hold their next exhibition at Olympia in the late autumn, probably November. All classes of vehicles and motor-boats may be represented, and the society point out that the most prominent builders of motor-boats are also carmakers, and that, as the purchasers are of the same class, both should be shown at the same time.

**The Institution.**—The provisional arrangements for the remainder of the session were announced last week. Beside the extra meeting called for last night to discuss Mr. Murray's paper, an additional meeting has been arranged for April 13. The dates are as follows: March 9, to read Dr. Glazebrook's report on "Temperature Experiments in Field Coils," and Mr. Goldschmidt's paper on "Temperature Curves"; March 23, to discuss same; April 6, to read congress report and Mr. Creedy's paper; April 13, to discuss same; April 27, to read and discuss Mr. H. Laws Webb's and Mr. A R. Bennett's papers.

**Permanent Way.**—Mr. Justice Warrington's dictum in the case of Tilling *v.* Dick, Kerr, and Co, reported in our last week's issue, that the London County Council's Act of 1900 does not confer power to execute works "in, over, or under the streets" for the purpose of providing a temporary service while reconstruction is proceeding, has led to prompt action on the part of the Council. At Tuesday's meeting the Highways Committee submitted a recommendation that a clause be added to the Council's pending Tramway Bill authorising the use of temporary raised tracks so as to avoid a cessation of the service. We expressed our views on this subject last week in a leading article.

**Niagara.** — The American public have apparently awakened to the fact that the Niagara Falls constitute a national property, and consequently a Bill is shortly to be introduced into the State Legislature to exact payment from all persons using the Falls to create power, as is done with regard to the other side of the Falls by the Dominion Government. The tax proposed is 6s. per annum per horse-power up to 20,000, and 4s. per horse-power from 20,000 to 30,000, and so on, the charge above 40,000 horse-power being 2s. Many enormous franchises were given away to the first American users of the Falls, and presumably these will continue to have the free use of this vast source of power unless some bold statesman introduces retrospective legislation.

**Motorcars and Electric Timing Devices.**—An electric chronometer recently devised by Lord Kelvin was responsible for the appearance of a batch of motorists before the Hayward's Heath justices on Monday, when some tolerably heavy fines were inflicted, besides three licenses being endorsed, for furious driving. An interesting episode occurred when Mr. Staplee Firth, the champion of oppressed motorists, questioned the reliability of the instrument. "But it was made by Lord Kelvin," protested the guardian of the law who effected the arrest. "Oh, I know that Lord Kelvin is very good at deep-sea sounding, but I never heard of him coming out with electricity before!" replied the defending counsel. Really, we scarcely know whether to regard the remark as ingenuous or disingenuous. If the former, Mr. Firth's scientific knowledge must be a long way behind his legal attainments; while if it were one of those little *ruses* practised by counsel for discounting the value of the other side's evidence, the effort scarcely seems a happy one, considering his lordship's world-wide reputation in electrical matters. Anyway, it was futile, and the motorist monster, or martyr, is threatened with another thorn in his side as the result of Lord Kelvin's contribution to delicate time-registering devices.

**Municipal Tramways Association.**—The managers' section of the Municipal Tramways Association held a conference in the Council House, Birmingham, last week. Mr. Alfred Baker presided, and there was a large attendance of members from the principal towns of the United Kingdom. Alderman Beale, the chairman of the Birmingham Tramways Committee, in extending the party a cordial welcome to the city, humorously described the Birmingham tramways as a collection of "old masters," which ere long will be superseded by a modern type. Mr. J. B. Hamilton (Leeds), the vice-president of the association, expressed the thanks of the members to Alderman Beale for his words of welcome. He remarked that if Birmingham was the last of the large towns to municipalise its tramways, it was the first to take the courageous step of providing through communication with the outside districts. The following subjects were subsequently discussed: "Overhead Equipment," introduced by Mr. J. M. McElroy, and "Tramway Telephones," introduced by Mr. Baker; "Local Taxation of Tramways" (Mr. E. Coutts), "Collection and Delivery of Parcels in Connection with Tramway Systems" (Mr. C. J. Spencer), and "Universal Indicators for Tramway Stopping Stations" (Mr. A. R. Fearnley).

**Electric Driving in Cotton Mills.**—A large cotton-spinning mill, to be operated entirely by electricity, is under construction for the Acme Spinning Company, Limited, Pendlebury. The energy will be obtained from the Lancashire Electric Power Company, who will transmit to the mill from their generating station at Outwood three-phase alternating current at 10,000 volts, which will be transformed down to 400 volts for driving purposes and 230 volts for lighting. Fine and coarse counts of cotton will be produced at the mill. As turbines are used for driving the dynamos at the power station a very perfect drive should be obtained on the spindles, which is, of course, a matter of great importance in the spinning industry, as thereby increased production can be obtained, and not only this, but the product itself is improved in quality. Exactly how much improvement there will be in these respects is one of the most important questions of the whole subject, the steam-engine makers insisting that with their most modern plant no cyclic irregularity occurs. As, however, this new mill is being built side by side with a steam-driven mill of the same proportions and under the

Digitized by Google

same management a very useful comparison will be instituted. If the electric driving succeeds as well as is hoped, it will be an incentive to other mill-owners to follow the lead.

**American Electrical Exports.** — The electrical exports from the United States during 1904 totalled some £2,250,000, this constituting a record. About 60 per cent. of this was represented by "electrical machinery," and the remainder by "electrical appliances." The totals for 1902 and 1903 were £200,000 and £1,971,220 respectively. Hitherto the United Kingdom had been the largest buyer, but for 1904 the figure dropped from £345,400 to £240,000, and Canada, with £320,000, was the largest customer during last year. The exports to France and Germany were both more than doubled, the figures being £25,500 and £38,000 respectively. In the course of the year the exports to Mexico were increased by nearly 20 per cent over the previous twelvemonth, £130,000 being the figure for 1904. The trade with South America was substantially increased. To the British East Indies goods to the amount of £40,000 were exported—more than to Germany or France. The exports to British Australasia rose from £45,000 to £80,000, and to British Africa from £14,000 to £27,000. The most notable feature of the year, however, was the expansion of exports to Japan, who, notwithstanding the war, took goods to the extent of £238,000 from the States—nearly four times the figure for any preceding year.

**Engineering Standards Committee.**—This committee is about to issue a report on "The Temperature Rise in Field Coils of Electrical Machinery," which will be of great service to electrical manufacturers. The report, which will be brought before the Institution of Electrical Engineers on Thursday next, deals with a vast amount of experimental work carried out at the National Physical Laboratory under the supervision of Dr. Glazebrook. We understand that the actual experimental work was performed by Mr. Rayner. The report deals with the question from two points of view, the first being the effect of heat on the electrical and mechanical properties of dielectrics, and the second the temperature distribution in the interior of the coils. The co-operation between the Engineering Standards Committee and the National Physical Laboratory in carrying out this work is exceedingly gratifying, and shows that the financial aid received from the Government in the establishment and maintenance of the laboratory is of practical service to the industry at large. The report will give ample evidence of the value of the researches to designers of electrical machinery, and will, we hope, tend to standardisation in the temperature limits allowable in such coils. We understand that the preface to the report has been written by Sir William Preece, the chairman of the Electric Plant Committee.

**Italian Railways.**—Bills relating to the working of the railways by the State have been introduced into the Chamber of Deputies. These provide for the Government undertaking the working of the State systems, which have been leased to two companies, whose concessions expire in July, and for the expropriation of the Southern Railways Company. It is reported that after the transfer has been completed the State will expend £20,000,000 in putting the railways on a good working basis, but no mention is made of electrification. The lessee companies conducted some trials a few months back with this end in view, the results being favourable to electric traction, for which the country possesses natural advantages. It was recognised, however, that the Government could not very well undertake the large expenditure involved without the co-operation of the companies, and the public incline towards the State working of the railways. This may account for the apparent shelving of the question for the present. Provision is made for considerable improvement in the position of the railway staffs, whose novel manœuvres have been described in the daily Press during the last two or three days. At first sight it seems an ingenious device to substitute such tactics for the intimidation sometimes practised by strikers, but by disregarding the convenience of travellers the employés made the fatal mistake of alienating the sympathy of the public, with the result that the movement has virtually collapsed.

**Electrical Investments.**—A glance at the share list of the electric lighting companies illustrates what a good investment the debentures and preferred stock of the representative concerns afford to the man who wants a return of 4 to 5 per cent. for his money coupled with good security. Taking a score of the leading metropolitan and provincial companies during the past year, their securities of the classes mentioned maintained a remarkably uniform level, notwithstanding that in some cases the shares were at a considerable premium. The stability of the securities is emphasised by the fact that this occurred in a year when consols fluctuated between 91⅜ and 85. The City of London Company's debentures and preferred stock were in especial favour, the former being, on the average, at a premium of nearly 25 per cent., while the preferred stock was never at a lower premium than 30 per cent. The debentures and preferred stock of the various companies carry dividends varying between 7 per cent. and 4 per cent. on the price of issue, but the return on the present prices averages about 4½ per cent., none of the securities varying much from this figure. Considering the comparatively short term of existence which these undertakings, unlike the metropolitan gas companies, have to provide against, and which may be expected to detract from their value in the eyes of the investor, the support accorded to their securities testifies to the confidence with which the public view the operations of electric lighting companies.

**Rating Government Telephone Wires.** — In December last we noted the fact that the St. Pancras Borough Council had passed the following resolution: "That the Postmaster-General be requested to consider as to making contributions in lieu of rates in respect of all Government telephone wires." The resolution was forwarded to Lord Stanley, M.P., and the Borough Council have now received from the Postmaster-General a copy of a letter which has been addressed to him on the subject by the Lords Commissioners of his Majesty's Treasury to the effect that the proposal involves an innovation upon existing practice which cannot be taken by itself. Before any changes can be introduced it will be necessary to examine other questions connected with the Government contributions in lieu of rates, and more particularly contributions in respect of properties subject to limited rating under special Acts, museums, and the like, and the cost of the fire brigade, and that the Government, if desired, would be prepared to move for or support the appointment of a Select Committee to enquire and report upon the whole system. The Borough Council have now decided to inform the Postmaster-General that they favour the appointment by the Government of a Select Committee. Surely, in this matter of telephone wires, any contribution in lieu of rates is equivalent to taxing local subscribers to lighten local rates. There can be no real gain from such a procedure, but it may require the report of a Select Committee to convince some people of this.

**The Ministry of Commerce.**—At a meeting of the Birmingham Chamber of Commerce the other day, it was reported that an unfavourable reply had been received from

Digitized by Google

Mr. Chamberlain anent the proposed Ministry of Commerce, which, after a period of peaceful repose since the committee of enquiry submitted its conclusions, was revived by the King's Speech. The right hon. gentleman stated that he could not see the advantage of calling the Board of Trade by another name, though amendments might be made in the organisation of the Department. It appears to us that the gist of the matter is embraced in the latter clause. Business men are not likely to feel greatly concerned about the designation of the Department, provided that it performs its duties efficiently. The new title would perhaps be the more appropriate, as disposing of the mythical "Board"; but this is a detail. If the alterations are not to go much beyond changing the title of the Department's presiding genius and increasing the emoluments of the office by 150 per cent., the outlook for increased efficiency is not brilliant. The scheme of reorganisation outlined by the Government, however, promises some useful reforms, not the least of them being the transfer of certain functions from the Home Office, which will avoid overlapping, and the removal of consular control from the Foreign Office. It is reported that if a Ministry of Commerce is decided upon, the first occupant of the office will be the Parliamentary Secretary to the Board of Trade (Mr. Bonar Law), who has fulfilled the latter position with considerable success. The minister will have the status of a first-class servant of the Crown, commerce being thus assigned a leading position in the Cabinet. A commencement might be made with the reforms by seeing that the Department's reports are compiled with a greater regard for accuracy, instead of being followed by a formidable list of errata, as has frequently happened of late.

**Electric Trams versus Motorcars.**—The astute gentlemen who preside over the destinies of the London United Tramways Company are evidently not among the believers in the supersession of the electric tram by the motorcar. In an interview last week, Mr. Clifton Robinson stated that within a few days contracts to the amount of £700,000 will be placed for the extension of the system. One result of this will be to bring the picturesque Surrey districts of Ewell and Esher within the range of a tram ride, the lines on the southern side of the river being linked with those on the Middlesex side by taking the rails over Kingston Bridge, for which the Board of Trade have given their consent. Another line will run from Kingston through Malden to Wimbledon and Tooting, where it will join the London County Council system. When these extensions are completed an important portion of the scheme for linking up the Metropolis and its environs by tramways will have been accomplished. Mr. Robinson summarises the rivalry between the two forms of traction in this succinct manner: "In my opinion the motor-omnibus cannot hope to compete with the electric tramcar. The working expenses of the tramcars average 6d. per mile against 1s. for the motor-omnibus. The electric car carries 70 passengers, and will run for 14 years, while the motor-omnibus carries only 32 passengers, and lasts only two years." Even if the life which Mr. Robinson allows the motorcar is rather too short, the electric tram has little to fear from that vehicle where anything like a frequent service is demanded, unless a radical change can be effected in its operating and maintenance costs, which, in the present position of mechanical science, does not appear likely. The motorcar may, however, have a useful sphere of utility before it, and if it brings the passengers along to the tram terminus from the less frequented localities, the trams will have cause to view it as an ally rather than an enemy.

**Fulham's Charges.**—The Fulham Borough Council considered on Wednesday a report from the borough engineer, Mr. A. J. Fuller, as to a proposed alteration in the charge for current for private lighting. Under the present system the charge is 5d. per unit for an average consumption of 12 units per 8-c.p. lamp per annum. If the consumption exceeds this, the price falls to 4d. up to 24 units, and beyond that the charge is 2d. per unit. We gather from the report that the objection to this scale is that the consumer has to pay at the 5d. rate for the first two or three quarters in the year, the reduction only coming into play at the last quarter. It will be seen that the system in use is a compromise between a flat rate and the maximum demand system. Mr. Fuller does not consider the latter system practicable, as he has found it lead to general discontent and cause great trouble. He also finds that the system now in force restricts the number of lamps which a consumer will put in a private house, in order that the consumption per lamp fixed may be high. He, therefore, recommended a reversion to a flat rate, and advocates a charge of 3½d. per unit. An alternative course left to the consideration of the Council was to charge 3d. per unit. This, Mr. Fuller calculates, would mean a loss for the first year, which would afterwards be recouped by the large number of new consumers obtained. It will be interesting to see in future years how the records of the load factor on the Fulham mains will compare with those of metropolitan boroughs where preferential rates are given to the long-hour consumer. We quite agree, however, with Mr. Fuller's contention that the price for electric light should be reduced to the lowest possible limit consistent with clearing, working expenses, interest, and redemption charges. The terms finally decided upon by the Council are as follows: a flat rate of 3½d. per unit, with a discount of 2½ per cent. on all bills over £2 per quarter, and 5 per cent. on all bills over £5 per quarter, if paid within 14 days. In this way the larger consumers will receive more favourable terms.

**City and Guilds of London Institute.**—The prizes and certificates awarded to students of the colleges and schools under the management of the City and Guilds of London Institute were distributed on Saturday at the Mansion House by the Lady Mayoress. The chair was taken by the Lord Mayor, and amongst those present were Sir John Watney (hon. secretary), Mr. Alexander Siemens, Prof. W. E. Ayrton, Prof. Silvanus P. Thompson, Dr. William Garnett, Mr. S. Stewart Gladstone (treasurer), and Prof. Unwin. Sir John Watney explained that the greater number of the students who received their awards that afternoon were evening students, who had attended one or more classes in the institute's colleges during last session. There were no evening classes at the Central Technical College, the work of that college being confined to providing systematic courses of day instruction, of a university character, in engineering and chemistry. At the close of last session 61 students from the Central Technical College, who had matriculated with distinction, were awarded the diploma of associate of the City and Guilds of London Institute, and with a few exceptions all these students had gone out into the world to commence their professional career as engineers. With regard to the extension to the Technical College, Finsbury, he stated that the work was making progress, and would, it was hoped, be completed before the end of next session. Mr. Siemens, who delivered the customary address to the students, said that when he first came to England, in 1867, there was hardly any technical college in the United Kingdom. Since then the subject of technical education had received an ever-increasing amount of attention, and nowadays everybody was alive to its value. The habits of observation, reasoning, and judgment should be inculcated

Digitized by Google

at every step during the whole course of studies. Such training, he observed, had the additional advantage that it prepared the mind for the constant stream of new discoveries that were crowding upon one another since the achievements of the last century had totally altered the conditions of living.

**British Association.**—The association have issued a notice in reference to the South African meeting, stating that members who propose to attend the gathering should send their names to the chief clerk not later than May 31. On receipt of their subscription they will receive a voucher entitling them to a reduction of 25 per cent. on passages booked at the offices of the Union Castle Steamship Line, and a certificate entitling them to a reduction of 50 per cent. on railway fares in South Africa. The council will assign to members in priority of application and seniority the limited number of free passes granted by the railway administrations. To participate in this advantage associates of former years must apply for full membership before May 31. Hotel expenses are estimated at 25s. per diem first class and 18s. second class. The acceptance of papers and the days on which these are to be read will be determined, so far as possible, by the organising committee of each section before the beginning of the meeting. It is therefore necessary, in order to enable the committees to do justice to such communications, that each author shall prepare an abstract of his paper, of a length suitable for insertion in the annual report of the association, which abstract, with the original paper, should be posted on or before June 15, addressed thus: "General Secretaries, British Association, Burlington House, London, W. For Section —." Authors who comply with this request, and whose papers are accepted, will be furnished before the meeting with printed copies of their abstracts. If it be inconvenient to the author for his paper to be read on particular days, he will be required to send information thereof to the recorder of the section in a separate note. Abstracts received after June 15 will appear in the annual report, but cannot be printed before or during the meeting. No report or abstract can be inserted in the annual report of the association unless it be in the hands of the assistant secretary before the conclusion of the meeting. The following are the titles of the sections and the names of the presidents who have been appointed by the council: Section A—Mathematical and Physical Science—Prof. A. R. Forsyth, F.R.S.; Section B—Chemistry—G. T. Beilby; Section C—Geology—Prof. H. A. Miers, F.R.S; Section D—Zoology—G. A. Boulenger, F.R.S.; Section E—Geography—Admiral Sir W. Wharton, K.C.B.; Section F—Economic Science and Statistics—Rev. W. Cunningham, D.D.; Section G—Engineering—Colonel Sir C. Scott Moncrieff; Section H—Anthropology—Dr. A. C. Haddon, F.R.S.; Section I—Physiology—Colonel D. Bruce, F.R.S.; Section K—Botany—Harold Wager, F.R.S.; Section L—Educational Science—Sir R. C. Jebb, M.P.

**The Judicial System and Technology.**—If our legislators are desirous of introducing a useful reform, they might well direct their attention to the constitution of tribunals for adjudicating upon cases involving technical questions. A letter on this subject recently appeared in a contemporary, and the writer made some cogent observations. Not long since Mr. Justice Ridley refused point-blank to try an engineering case, frankly confessing his ineligibility for that function. This state of affairs has, of course, long been recognised in the Admiralty Division, where nautical assessors come to the rescue of the learned judge. An arrangement of this kind is obviously the rational solution of a somewhat complex situation, for a judge, however capable a lawyer he may be, cannot be expected to be conversant with marine engineering—a remark which applies with equal force to other branches of technology. The Bar certainly includes in its ranks men who have devoted a large amount of attention to technical matters, notably Mr. Fletcher Moulton, who is not only an ornament of the legal profession, but is a member of the Institution of Civil Engineers. The advantage to litigants when one of these "specialists" ascends the Bench is, however, very limited, since there is no arrangement for assigning actions to certain judges because of particular qualifications. Patent Office officials are very rightly required to possess some technical qualifications, if not of a very advanced character, and there is an obvious need for similar knowledge being at the disposal of a high functionary who has often to decide complicated questions of infringement and other important technical matters. A few years ago a section of the King's Bench Division was constituted into a "Commercial Court." If the Bench always included a capable scientist among its members, it might be practicable to establish a "Technical Court," but this is rather too much too expect, as there is no particular affinity between law and science. The best method would therefore appear to be to follow the precedent of the Admiralty Court, and have experts in attendance to guide the judge upon technical points, as recommended by the correspondent referred to above. It is true that litigation is already expensive enough, but suitors would not be likely to object to any reasonable extra cost resulting from this innovation. That our judicial system has, with the exception mentioned, dispensed with such an arrangement hitherto, is certainly no reason for continuing the practice, as experience has shown that in many cases it is unsatisfactory to judge and litigant alike. The various institutions might do worse than adopt the hint of the above-mentioned writer, and consider the matter with a view to making representations to the authorities.

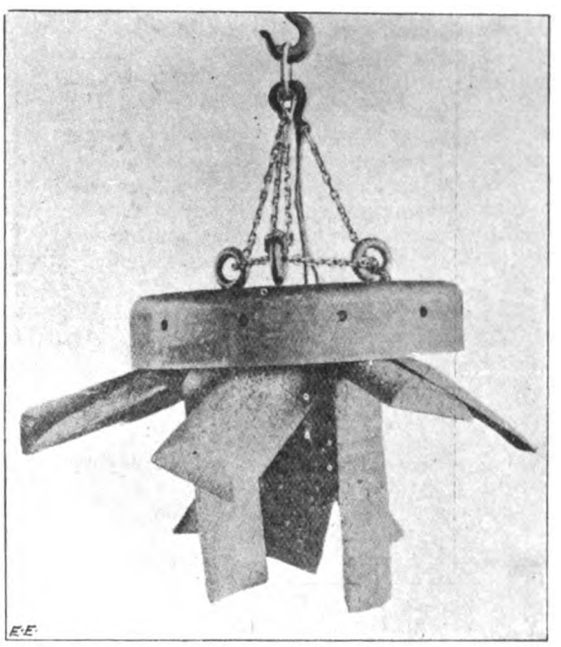
**Load Factor and Cost of Power.**—We have received an advance proof of an interesting paper to be read before the Canadian Society of Civil Engineers. The author is Mr. E. M. Archibald, B.Sc., and his method of treatment shows that he has carefully investigated the question. He points out, in the first place, the desirability of obtaining customers who have a steady load for a large number of hours per day, and that these should be offered lower rates than those who only require energy for a short time. He then proceeds to show by means of curves how much the cost of power is decreased with an increasing load factor, and consequently how much the charge for energy can be reduced to customers who require supply with a good load factor. The subject is investigated by means of curves, assuming a definite capacity of plant and peak load. Curves are then given to show how the total operating expenses vary with the load factor and with the cost of coal, which becomes the all-important item at high power factors. For the smaller station investigated, 900 kw. of plant is assumed, working first with condensers and then non-condensing. The author then proceeds to deal with a power station of twice this size, working condensing. In the smaller station he assumes that coal-handling apparatus, automatic stoking, etc., will not be warranted unless a load with a good power factor can be obtained. With the larger station labour-saving devices are included, and it is shown that the extra investment for providing these will reduce the cost of labour and fuel to a greater extent than the fixed charges are increased. In all the examples treated in the early part of the paper steam plant is assumed, but the last curves given are for a station working with gas-engines supplied

Digitized by Google

by means of producers. A comparison of the author's curves shows that, with the conditions he assumes, the gas plant is the more economical at high load factors, but less economical than steam at low power factors, due to the influence of the heavy fixed charges. It also follows, naturally, that the higher the cost of coal the greater the advantage of the gas-producer station over one using steam boilers and steam-engines. The figures assumed by the author are for Canadian conditions, but it is interesting to note that in his fixed charges he allows 5 per cent. interest on the capital outlay, 10 per cent. for depreciation of machinery, 3 per cent. for depreciation of buildings, and 2 per cent. for taxes and insurance. The depreciation is somewhat higher than is allowed as a rule in this country. The obvious conclusion from the author's curves, that a maximum demand system of charging is the correct one to adopt in all power supply, is not pressed home by the author; but in one set of curves he shows what the average charge for electrical power should be to consumers with different load factors.

**The Present Shrinkage of the Earth's Magnetism.**—A paper on this subject was read by Mr. L. A. Bauer before the American Physical Society, the February number of whose *Journal* contains an abstract of same. The author observes that the values of the earth's magnetic moment as derived by various analysts for the period 1843 to 1885 show a diminution for the interval of 40 years of about 1·6 per cent. Computations of the earth's total magnetic energy made by the author for the same period proved that the shrinkage in the portion equivalent to a uniform magnetisation was not compensated by a corresponding increase in the remaining portion of the earth's magnetism. As all of these results, however, were obtained on the basis of the distribution of the earth's magnetism as portrayed by the existing magnetic charts, which owing to paucity of data especially in the oceanic areas, are more or less inaccurate, the deductions regarding a possible shrinkage of the earth's magnetism could not be accepted as absolutely conclusive. In the present paper the results derived depend on actual observations between 1890 and 1900 at a series of land stations fairly uniformly distributed over the earth and lying between the parallels 60deg. N. and 60deg. S, the same number of stations having been selected in each magnetic hemisphere. From the mathematical analysis of the secular variation of the earth's magnetism between 1890 and 1900, it is found that the observed secular variation in the uniform portion of the earth's magnetism is to be ascribed to systems of magnetic or electric forces, two of which are as follows: (1) A system situated below the earth's surface, having a potential and acting in opposition to the earth's momentary field, hence demagnetising it. The magnetic axes of this system of forces besides being reversed with reference to that of the earth's momentary field is also displaced towards the west, so that its effect is to cause the north magnetic pole to move westward and southward and to diminish the earth's magnetic moment at the rate of about one twenty-two-hundredth part annually. (2) A system situated above the earth's surface, also having a potential, having its magnetic axis directed nearly transverse to the earth's axis of rotation. This system plays a most important part in the secular variation of the magnetic declination. The annual rate of shrinkage of the earth's magnetic moment for the period 1890 to 1900 is practically the same as that deduced on the basis of the magnetic charts for 1843 to 1885, adopting the mean of the two ratios we find that the earth's magnetic moment has been shrinking since 1840 at the rate of about one twenty-four-hundredth part of its prevailing value annually. At this rate the earth's magnetic moment will have dwindled to one-half its present value in 1,600 years. However, we have not yet sufficient grounds for such predictions. All we know is that a shrinking is occurring now, and the indications are that this shrinkage will be found to have been prevailing as far back as our available data extend. It is thus found that the secular variation of the earth's magnetism results not only from a change in the direction of the axis of magnetisation, but also from a change in the intensity of magnetisation.

**Electro-Lifting Magnets.**—The economies effected by electro-lifting magnets are the subject of an article in the San Francisco *Journal of Electricity, Power, and Gas.* The experience in steel mills and similar works where steel or iron in quantities is handled by means of cranes, shows that the saving in time and labour resulting from the introduction of electro-lifting magnets is sufficient to pay for the apparatus in from one to six months. A flexible twin conductor conveys the current to the magnet, which is suspended from the hook of the crane. A small switch operated by the crane-man is usually the only additional apparatus necessary. The amount of current used is small, being from one to 12 amperes, according to the service for which the magnet is designed.



As will be seen from the accompanying illustration of the magnet hoisting iron slabs and billets, the operation is very simple, the magnet being lowered upon the material and the switch closed, thus causing the magnet to attract the material. Having transported this to the desired spot, it is released by opening the switch. The magnets have been found of great value in moving small articles such as pig iron, scrap, rivets and bolts, and are extensively employed by the Illinois Steel Company, who have found the economy in time and labour so substantial that they have decided to introduce them in their works wherever possible. In general, the attachment of the load to the magnet and the detachment from same may be performed by the crane operator, no other hand labour being required, and the rapidity with which the articles are moved increases the service capacity of the crane. A single design of magnet is not adapted to handling all classes of goods, and the form of the articles should be carefully considered in constructing the magnets. The magnets are invariably tested to hold several times the specified load, and accidents are practically unknown.

## BRIDLINGTON ELECTRICITY WORKS.

The reputation of Bridlington is such that an apology is almost necessary for the reminder that it is a popular

THE MAYOR OF BRIDLINGTON, MR. C. E. FIELD.

MR. J. V. MAINPRIZE, CHAIRMAN OF THE ELECTRICITY COMMITTEE.

and delightful resort situated on the shores of a magnificent bay some four miles south of Flamborough Head, 47 miles from York, and 30 miles from Hull. The borough has a population of about 14,500 inhabitants, and consists of the old town and the quay. The former, with its fine Priory Church and picturesque surroundings, is closely associated with the past. The latter is of more modern construction, and is the business centre of the town. The persistent increase which has taken place during recent years promises to destroy the distinction between the two parts of the town, and unite them in a prosperous and enterprising whole. Bridlington is an ancient market town under a charter granted by King John in 1200, but the history of the town can be traced back to an even earlier period.

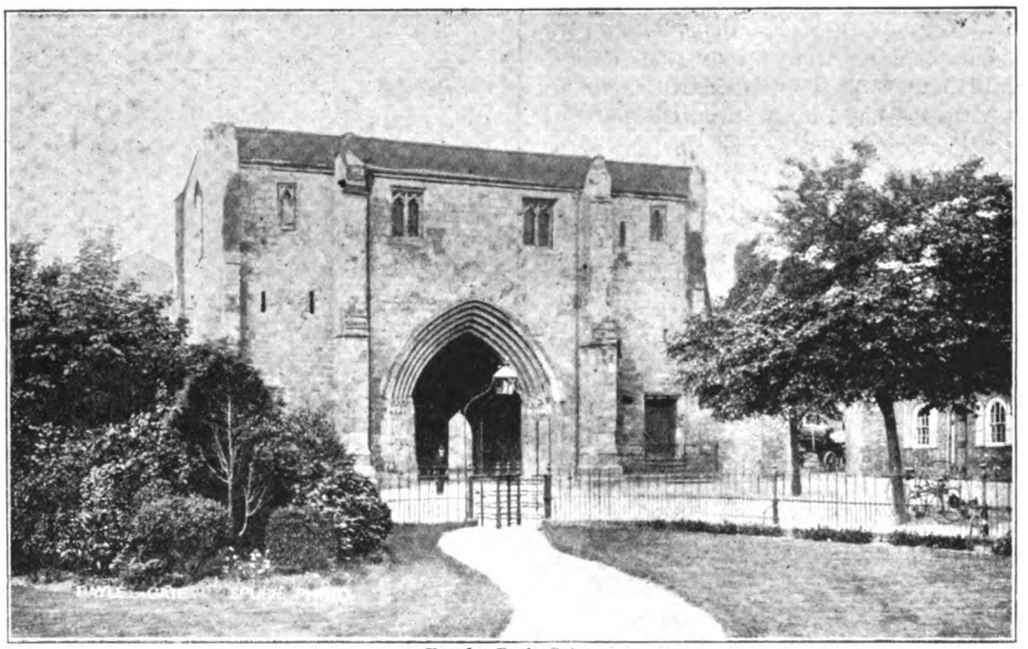

FIG. 1.—Bayle Gate.

MR. A. E. MATTHEWMAN, TOWN CLERK.

MR. F. H. MEDHURST, CONSULTING ENGINEER.

Many circumstances combine to prove the existence of a Roman station at or near the place. Bridlington was certainly a place of importance at the time of the Conquest, and increased throughout the twelfth and three succeed-

Digitized by Google

ing centuries, during which time the monastery, founded in 1136, attained a considerable degree of magnificence and power. The monastery was dissolved in the reign of Henry VIII., when the revenues were seized and the buildings demolished, with the exception of one portion,

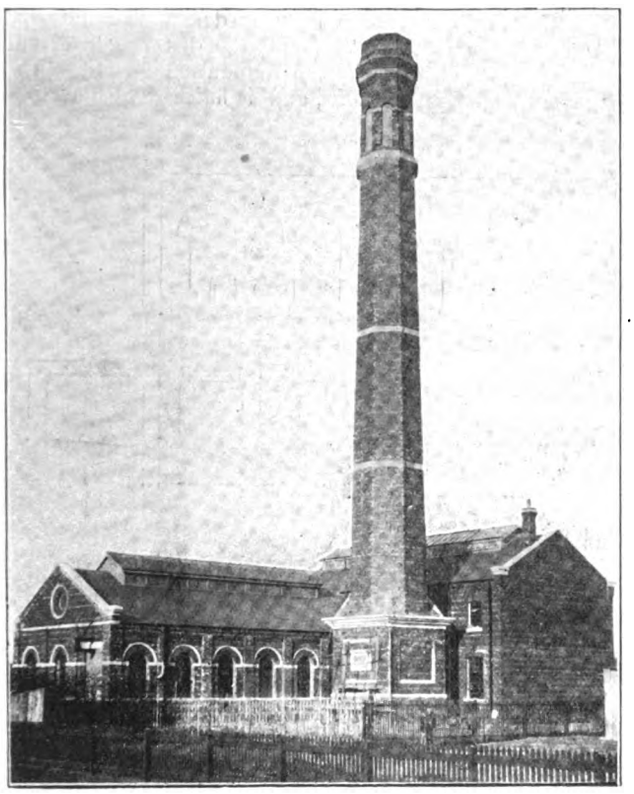

FIG. 2.—Exterior View of Buildings.

which served as a parish church, and the building now known as Bayle Gate (Fig. 1). This formed part of the outer walls of the monastery. The manor of Bridlington at one time belonged to the Priors. It was purchased in 1630 from Sir George Ramsey by the freeholders, who periodically elect from amongst their number 25 persons known as feoffees, of whom 13 are called lords and 12 assistant lords. Up to 1863 the lords feoffees had the general control of public matters, but in that year a local board was formed to carry on the government of the town. In 1895 the Local Board was superseded by the Urban District Council, and this in its turn gave place, on Nov. 9, 1899, to the Corporation, Bridlington being made a borough by Royal charter on that day. Amongst the memorable events of the past was a bombardment of the town during the Civil Wars in 1653, and in 1779 a sea fight in the bay between Government vessels and those of Paul Jones, the pirate.

Bridlington possesses a harbour, partly enclosed by stone piers. On the north side of the harbour the Royal Prince's Parade, opened in 1867, is now being extended, while to the south are the Spa Gardens, with fine promenades and a concert hall. The town and district offer many attractions to visitors—good boating, fishing, and bathing, miles of firm clean sands beloved of children, first-class bands, and a fine parade with gardens laid out on ground reclaimed by the construction of the sea-wall. The climate is bracing and equable, and the water supply excellent. The history of electric lighting at Bridlington does not lend itself to any extended treatment, though it is of interest to note that the lighting of the Royal Prince's Parade has for many years past been carried out by a gas-driven arc lighting set. So long, indeed, has this plant been in operation that the dynamo is one of the earliest type of arc-lighting machines.

The inception of the works to be described dates back to the summer of 1899, when communications were received by the then Urban District Council from several companies who were desirous of obtaining an electric lighting order for the district. Instead of approving any of these schemes, the Council decided to apply for a provisional order themselves, a course of action strongly advocated by Mr. W. C. Townsend, the chairman of the Electric Lighting Committee. The Council then invited Mr. F. H. Medhurst (of the firm of Messrs. F. H. Medhurst, Page, and Lloyd, of London and Manchester) to report on the whole subject, the result of his investigations strengthened their previous convictions, and the Bridlington electric lighting order was duly confirmed in the course of the following year.

In 1902 the question of establishing electricity works was again brought forward, and it was resolved to proceed at once with the construction of the works. Mr. Medhurst was appointed consulting engineer, and requested to prepare plans and specifications for a scheme of both public and private lighting on the three-wire, low-pressure

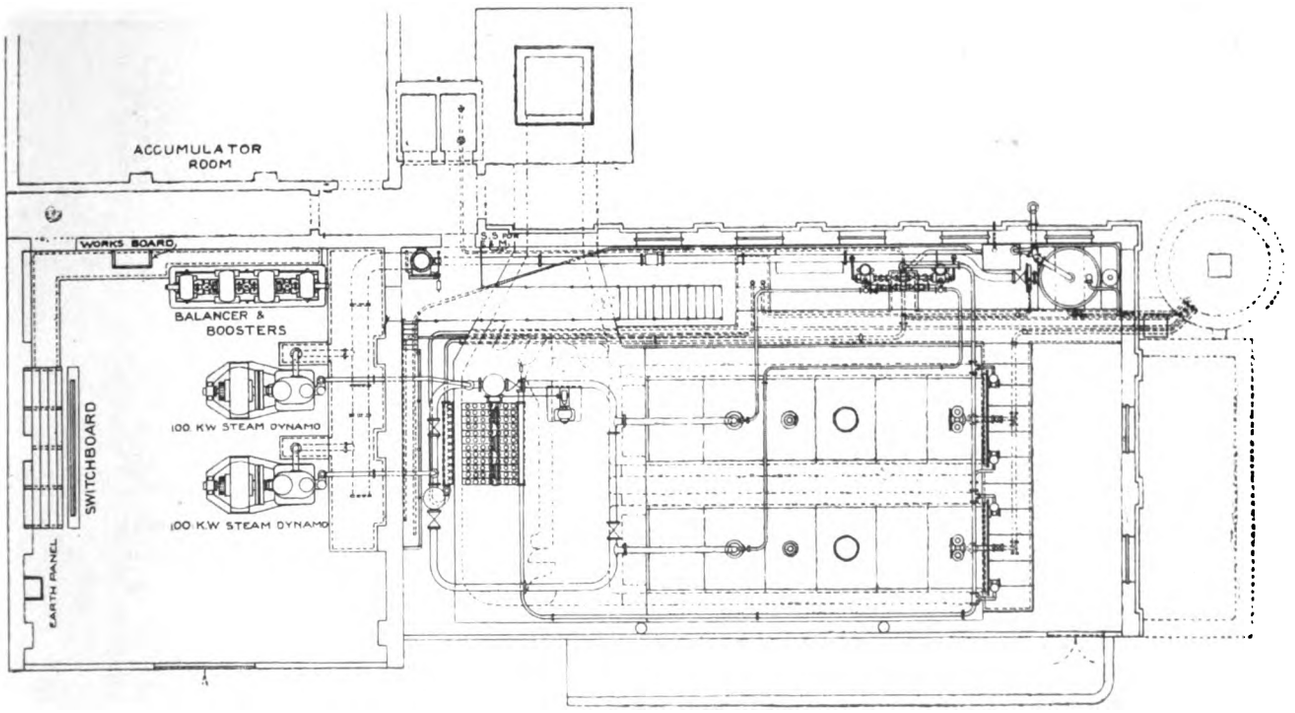

FIG. 3.—Plan, showing Arrangement of Plant.

system, with a pressure of 220 volts at consumers' terminals. Tenders were invited in March, 1903, and provisionally accepted. A pause of seven or eight months then ensued before the Local Government Board enquiry was held. The sanction of that Department to the borrowing of £26,481 was received early in 1904, and

Digitized by Google

it may be remarked that the estimates of expenditure have proved practically correct. The outlay is, in fact, almost identical with the estimates in Mr. Medhurst's report of 1900.

Work was commenced on the various contracts in January, 1904, and a glance at the names of the contractors given below will show everyone connected with the electrical industry that the Corporation have been well served, an impression which will be confirmed by an inspection of the works: Buildings and chimney shaft, G. Storr and Son, Bridlington, £5,238; boilers, Clayton, Son, and Co., Limited, £1,413; steam-pipes, etc., John Spencer, Limited, £1,429; steam dynamos, balancer booster, switchboard, Johnson and Phillips, £3,317; storage battery, Electrical Power Storage Company, Limited, £1,067; mains, Anchor Cable Company, Limited, £9,251; lamp posts and fittings, British Prism Globe Electrical Company, Limited, £2,597.

The buildings (Fig. 2) designed by Mr. Ernest R. Matthews, the borough engineer, are situate in a central position close to the Elms estate, recently acquired by the Corporation. Their general appearance is a credit to all concerned. Red Armitage bricks have been used in the ventilators in the roofs. The boiler-house and engine-room have temporary ends of galvanised iron, so that the buildings can be readily extended, an ample space for this purpose being available on the site.

The chimney shaft, 130ft. in height above the ground level, is a massive octagonal structure with a square base. The shaft is built on a block of concrete 23ft. square and 8ft. thick, reinforced with steel girders. The internal diameter of the shaft is 7ft., and the distance from the surface to the bottom of the foundation is 24ft. The base rises to a height of 20ft., and is finished with a stone cornice. The chimney stack is relieved by bands of stone at intervals of 30ft., and the top is treated in an ornamental style with white brick panels and a stone cornice, the whole being surmounted by a cap of the same material. Access to the engineer's office, meter-room, and lavatory on the first floor is obtained on the north side of the buildings. These rooms are over the battery-room, which is separated from the engine-room by the entrance lobby. The engine room is on the west side of the office block, and runs parallel with the boiler-house (see Figs 3 and 4). The latter section of the works is 33ft. 6in. in length, 63ft. wide, and 25ft. high. The floor is paved with concrete and has been sunk some 8ft. below that of the engine-room to facilitate the delivery of coal into the bunkers. The bunkers have a capacity of 25 tons of coal, and are roofed with concrete carried by steel joists. An inclined footway of blue Staffordshire brick leads to the ground

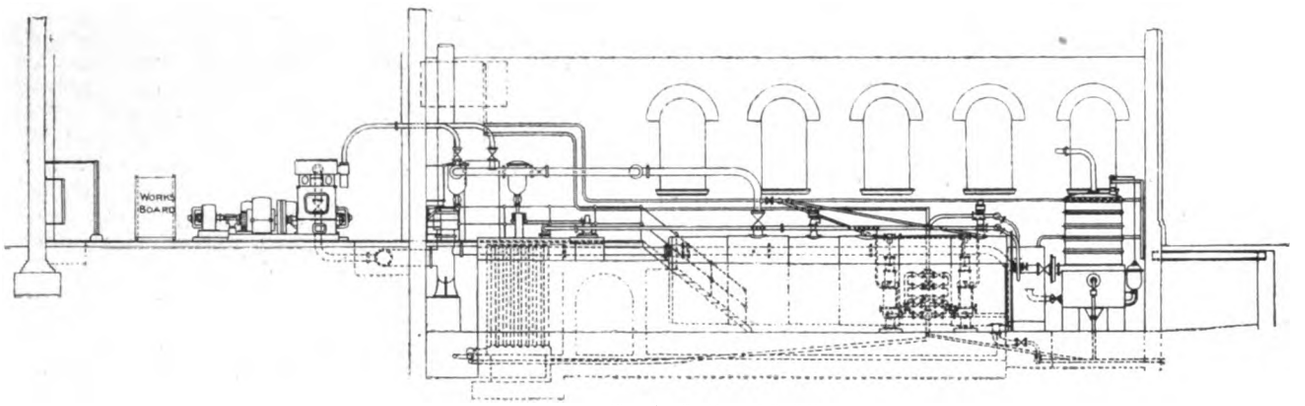

FIG. 4.—Section of Buildings.

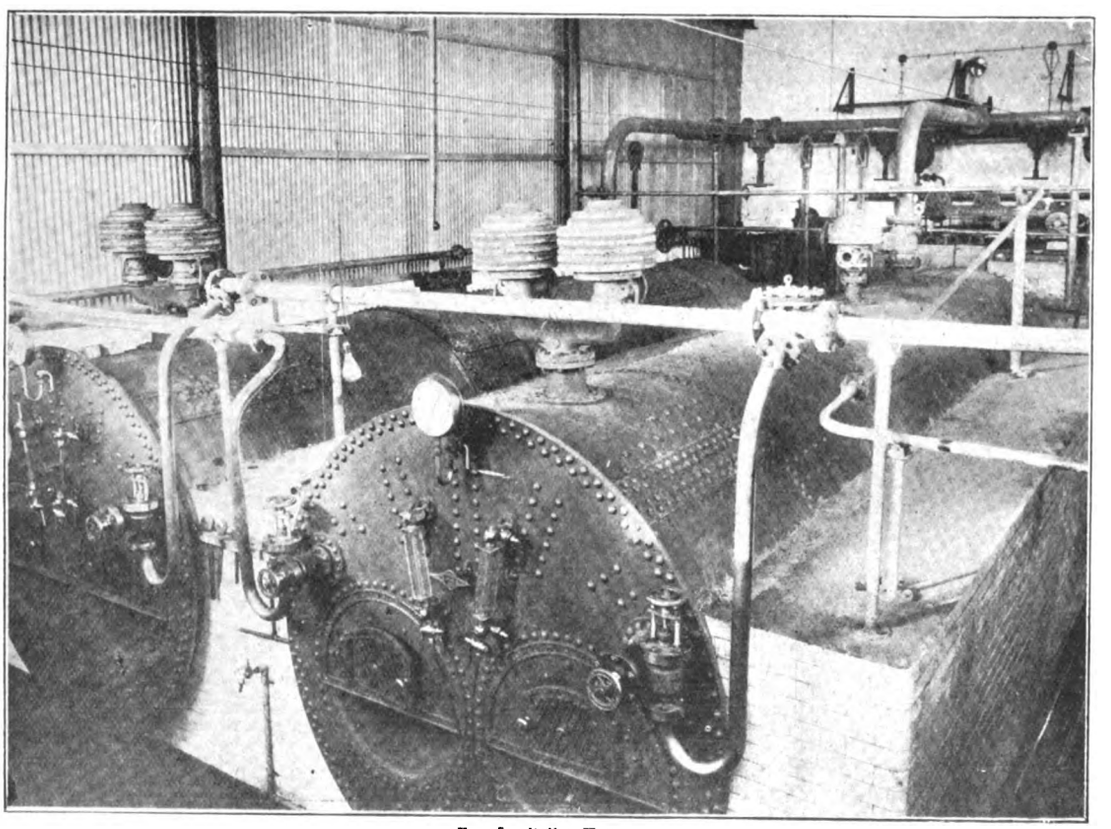

FIG. 5.—Boiler House.

construction of the work, and the exterior is ornamented with stringcourses and window mouldings of Robin Hood stone. Considerable attention has been given to lighting and ventilation. Large windows with semicircular heads and hopper ventilators are fitted throughout in addition to

Digitized by Google

level, and is used for the removal of ashes and clinker. Ventilation is obtained by louvre ventilators in the roof and by seven large windows with hopper ventilators.

The steam-raising plant (Fig. 5) comprises two Lancashire boilers. Each boiler is 7ft. 6in. in diameter and 30ft. in length, and is capable of supplying steam for both the steam dynamos. The working pressure is 135lb. per square inch, but the boilers have been designed to carry 150lb. per square inch, so that there may be an ample margin of strength to allow of some deterioration when the boilers get old without the necessity of reducing the working pressure. The boilers are seated on Poulton blocks, the brickwork is faced with white glazed bricks, and the boiler fittings are of Dewrance's and Turnbull's manufacture. A 96-tube Green's economiser is placed in the main flue, and its scrapers are driven by a 1½-b.h.p. motor. The feed water is pumped through this apparatus on its way to the boilers, and absorbs the heat from the flue gases, which pass between the sets of tubes to the chimney shaft. The temperature of the water can be increased by this arrangement from 212deg. Fah., at which it issues from the water softener, to 300deg. Fah. or more.

The boiler feed pumps are vertical compound Hall pumps, each designed to deliver 2,000 gallons of water per hour against a pressure of 150lb. per square inch. The exhaust steam from these pumps is taken to the feed-water heater. The pipe system has been arranged so that steam can be supplied to either or both the steam

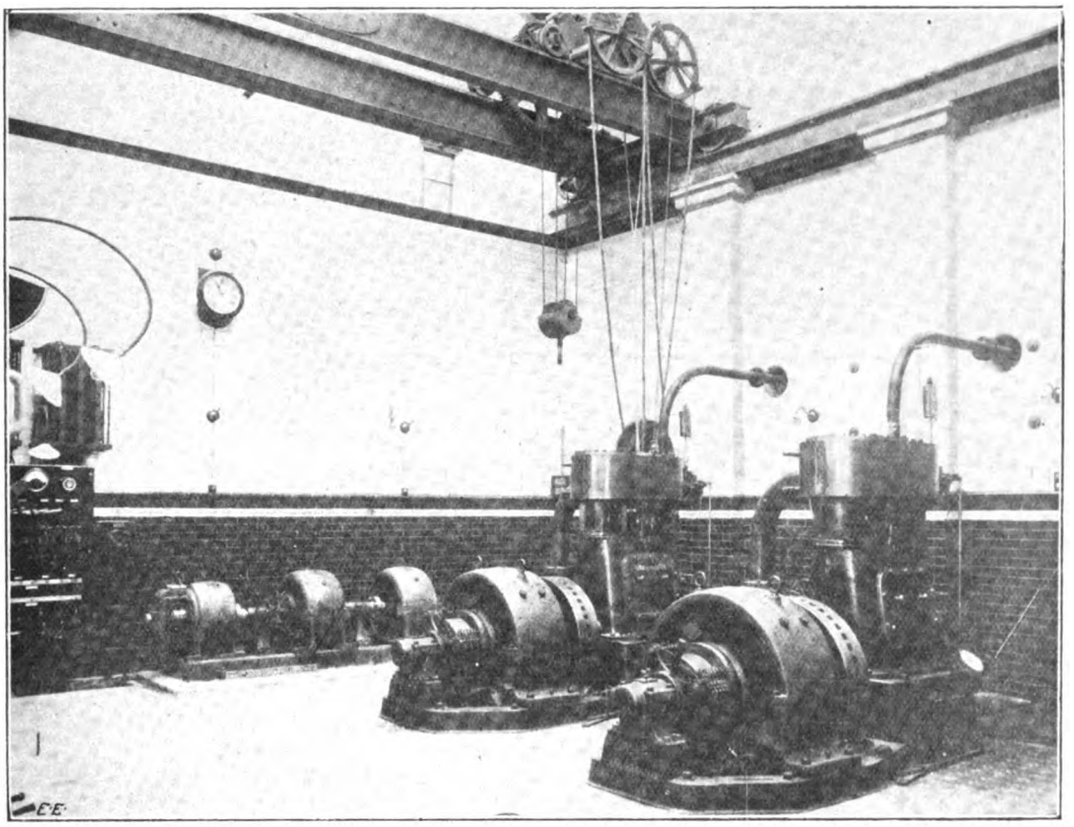

FIG. 6.—Engine Room.

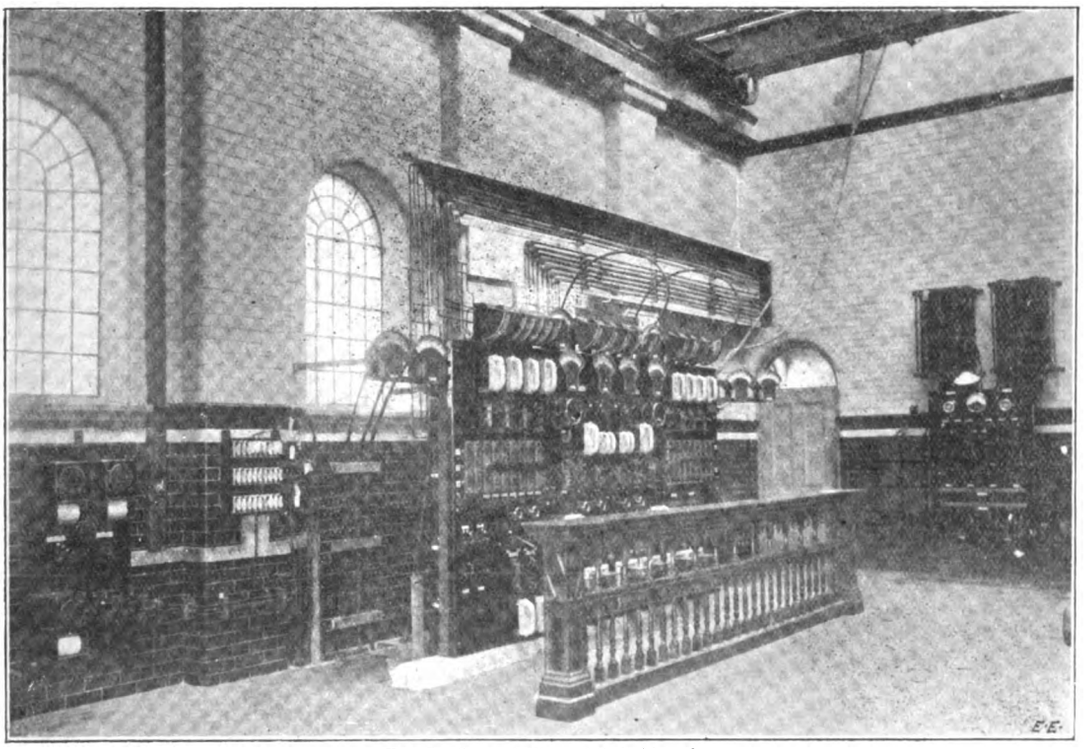

FIG. 7.—General View of Switchboard.

Digitized by Google

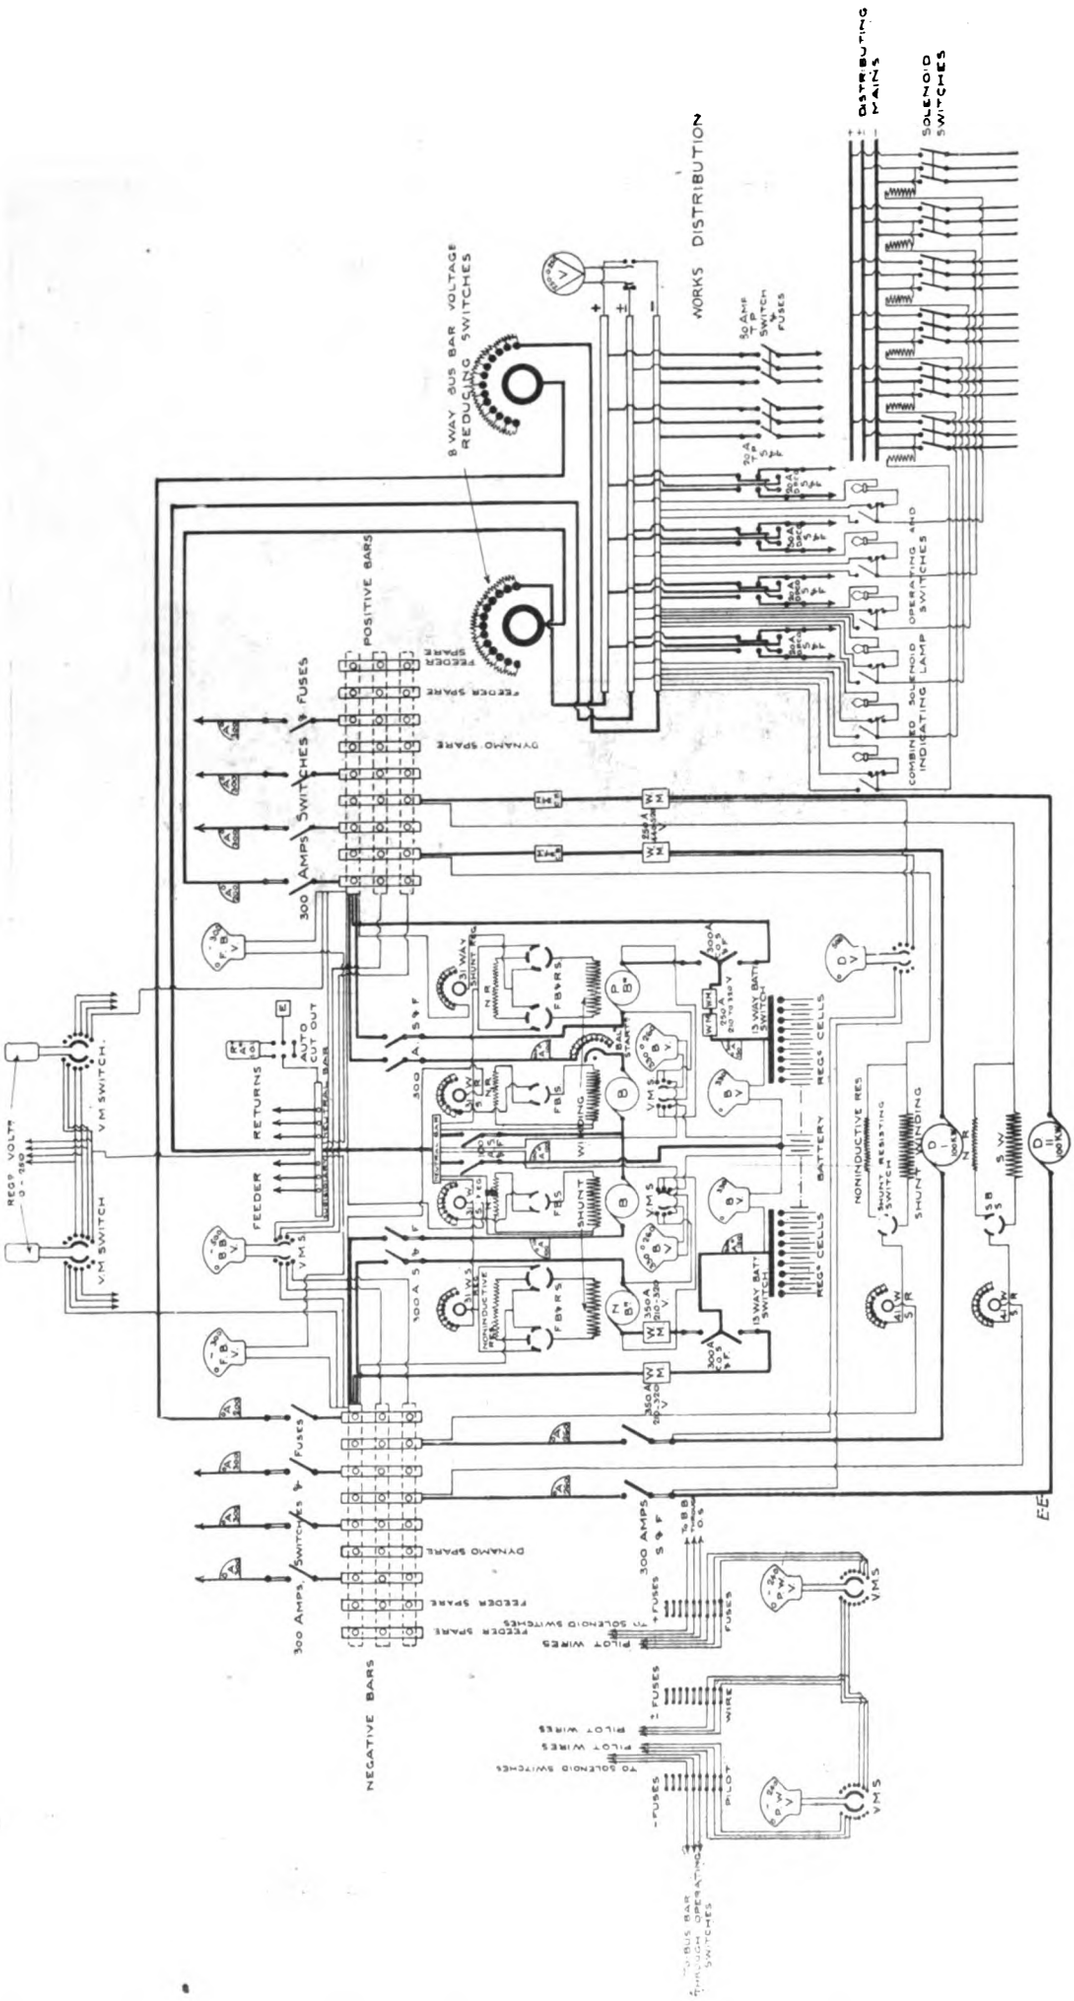

Fig. 8.—Diagram of Switchboard Connections.

dynamos from either boiler; the steam-pipes are of mild steel with welded flanges. These pipes are drained through contraction traps to the feed tank, and a duplicate feed-water service is provided for each boiler. The drains

Digitized by Google

from the boilers, economiser, and water softener are taken to a sump outside the boiler-house. The valves on the steam and feed pipe systems are made by Templer and Rance and J. Blakeborough and Sons. The pipework, including valve bodies and flanges, is lagged with removable mica coverings, canvas wrapped, and painted.

The water supply is taken either from the Corporation mains or from a tank placed above the men's lavatory. This tank is supplied by water pumped from a well by the feed pumps, as it has been found that there is an ample supply of good water available on the site for all purposes. From the tank it gravitates to the Boby-Chevalet feed-water heater and softener, or detartariser. This machine has been installed to reduce the hardness of 1,500 gallons of water per hour from 20 or more degrees to 4deg. of

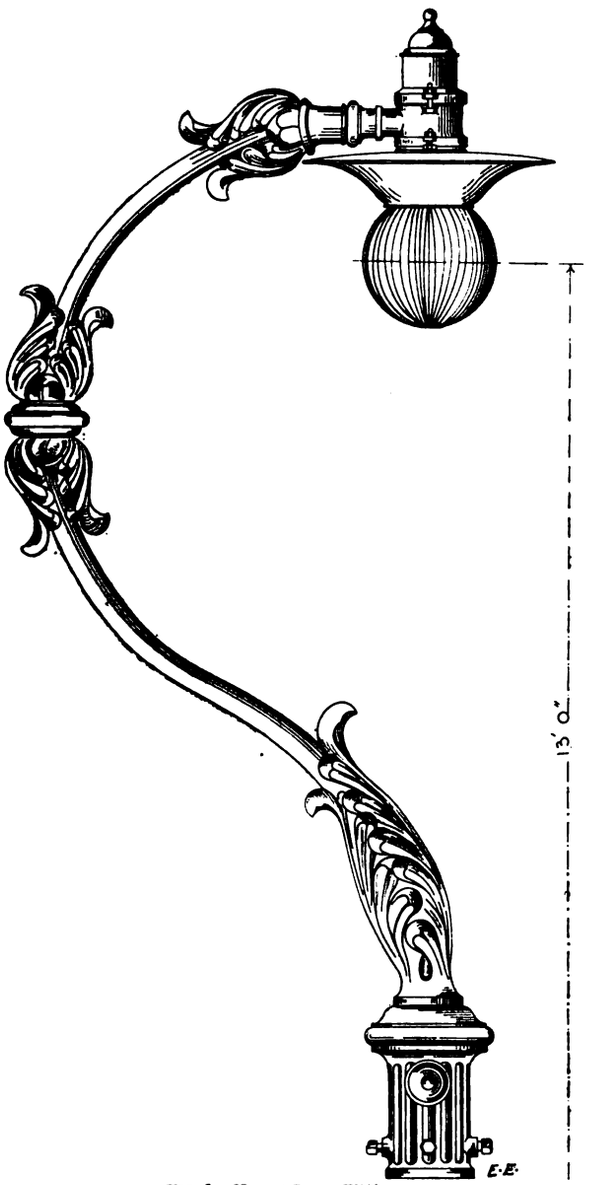

FIG. 9.—Nernst Lamp Fitting.

total hardness, and to raise its temperature at the same time to boiling point. The apparatus is worked by the exhaust steam from the dynamo engines, and consists of a series of trays in which the deposit from the feed water is thrown down by the heat from the steam. The machine is readily dismantled, and the trays when full are lifted by a travelling pulley block, passed through the door behind the heater, and emptied outside the boiler-house. This procedure saves time, and prevents an accumulation of litter and dirt in the gangway. An iron staircase from the north end of the boiler-house leads to a platform over the flues. Here are two doors, one communicating with the exterior of the building, the other with the engine-room.

The engine-room is 36ft. in length, 32ft. in width, and 25ft. to the springing of the roof, and presents a fine appearance. The walls are faced with glazed bricks to a height of 18ft.; the dado is of chocolate-coloured bricks, and is 6ft. in height. The walls above the glazed work are rendered with Parian cement and colourwashed. Mellowes glazing has been used in the roof, and the sashes in the lantern lights are controlled from the floor level. The floor is paved with Staffordshire encaustic tiles. A 10-ton overhead travelling crane, supplied by Marshall, Fleming, and Jack, spans the room, and the electrical equipment consists of two 100-kw. Allen-Johnson and Phillips steam dynamos (Fig. 6), with the usual accessories. The engines, each of 160 h.p., are of the double-acting vertical compound enclosed type, with forced lubrication, and their speed is 475 revolutions per minute. The dynamos are each capable of supplying some 4,000 lamps of 8 c.p. No condensing plant is installed at present. The matter, however, received due consideration in the first instance, and arrangements have been made in the lay-out of the works for the provision of this plant and a cooling tower as soon as the load warrants its adoption.

The balancing set stands on the east side of the engine-room. These four machines have a speed of 1,000

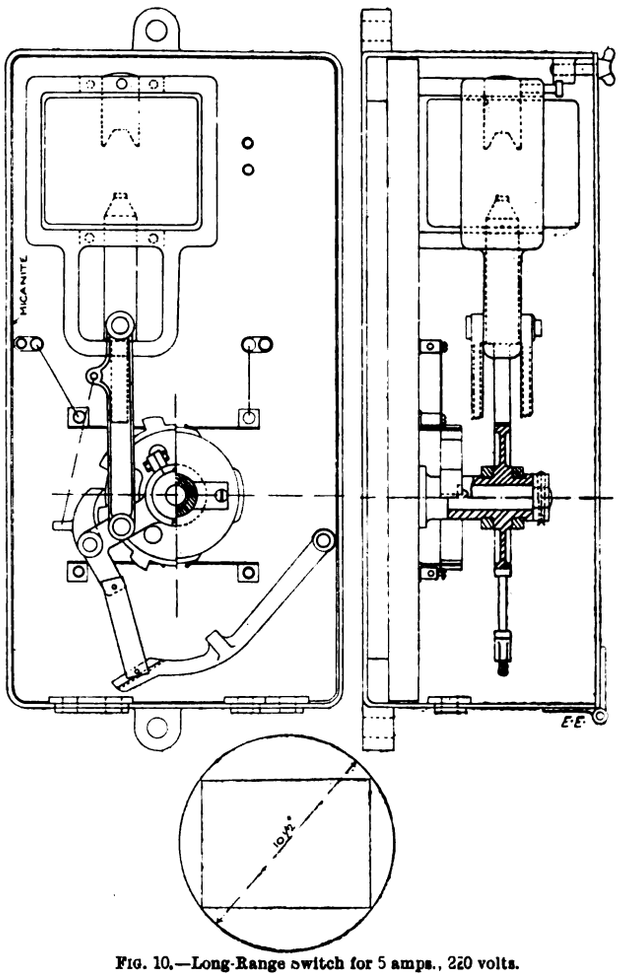

FIG. 10.—Long-Range Switch for 5 amps., 220 volts.

revolutions per minute. Their duty is to regulate the electrical pressure on each side of the system of mains and to assist in charging the storage battery.

The switchboard (Fig. 7) is erected some 4ft. from the north wall of the building. The board is built up of polished slate panels fixed to a metal frame, and is of neat and substantial design. It is equipped with the usual regulating and measuring instruments, and is of fire-proof construction. Bare copper connections run from the board to the storage battery. The main cables to the town and to the dynamos are brought to alternate copper bars on this board, so that any cable can be connected to either dynamo. The connections to the main switchboard are shown in Fig. 8. A smaller switchboard for controlling the street lamps and the lighting of the works is placed near the balancing set.

A very complete system of mains has been laid in the borough. Three feeder cables radiate from the works to different centres, or feeding points, and are there connected in suitable pillars to the distributing mains. The total length of mains for all purposes is 30 miles. Each

Digitized by Google

main is made up of three cables of stranded copper wire well insulated from each other. A lead sheathing is placed over the insulation, followed by a serving of jute yarn; two thicknesses of steel tape are then wound on spirally, and a further covering of jute yarn completes the cable. The mains are laid direct in the ground.

The street-lighting consists of 410 incandescent lamps of varying candle-power, and 32 arc lamps. Sixteen of the latter are 12-ampere open-type lamps of 1,000 c.p. each, and the remainder 500-c.p. 3-ampere enclosed lamps These lamps are of Messrs. Johnson and Phillips and the Reason Manufacturing Company's make, and will burn for 30 and 90 hours respectively without recarboning. The incandescent lamps are hung from graceful brackets fitted with special light-diffusing globes Some of these lamps are of the Nernst type (Fig. 9). The street-lighting is divided into four groups, and is switched on and off from the works. There are 26 "all night" lamps, 16 of which are arc lamps. These are switched on and off in the same way. Some 4,160 8-c.p. lamps are being supplied at the present time, or will shortly be connected, so that the undertaking starts with excellent prospects.

Although in the main the whole installation is laid down on lines which are well known to all engineers, there are one or two points in which the ordinary practice has been departed from, which are worthy of special attention. The water supply is one of the special points referred to. It was found when excavations for the foundations were in progress that at a depth of about 8ft. from the ground level a large supply of water was met with, and, in fact, this water interfered to some extent with the progress of the works. It was arranged to collect all this water by means of special drains into a large sump, and as the water was found to be of good quality it was decided to use it for feeding the boilers instead of pumping it away, as would otherwise have been necessary. This arrangement obviated the necessity of a well for which provision had been made. Another unusual feature is the method of controlling the street-lighting, the whole of which is switched on from the station. This is effected by six small switches on the works board, which in their turn operate long-range switches (Fig. 10) fixed in various parts of the town.

The borough has been fortunate in its Electricity Committee, who have throughout laboured hard for the success of the scheme under the guidance of their energetic chairman, Councillor J. V. Mainprize. The Mayor and Corporation have consistently backed up the efforts of the committee. The policy of the committee has been a happy mean between that excessive caution which in some well-known instances has greatly hampered the success of similar municipal schemes and the extravagance which has characterised others. Every step has been considered carefully, and nothing has been left undone which could attract consumers or help to make the scheme a success. In the spring an elaborate pamphlet was issued by the Corporation to all householders setting forth the advantages of electricity for various purposes. The whole of the street-lighting has been taken over from the gas company, a step of the greatest importance in the interests of the electricity scheme. The town clerk (Mr. A. E. Matthewman, B.A., LL.B.) and the borough engineer (Mr. E. R. Matthews, A.M.I.C.E.) have thrown themselves willingly into the project, while the consulting engineers (Messrs. F. H. Medhurst, Page, and Lloyd) have spared no pains to produce successful works by the adoption of the best modern practice in all departments. Mr. Arthur J. Beckett was selected in the spring of 1904 as clerk of works, from a very large number of applicants, to supervise the erection of the works under Mr. Medhurst, and on the completion of the works he was appointed by the Corporation as the first holder of the position of borough electrical engineer. His past experience in similar works has stood him in good stead, and the undertaking may safely be expected to flourish under his guidance.

In short, the installation of the works has been marked by a smoothness and absence of special difficulties which has been a source of satisfaction to the consulting engineers, and has led those responsible for the installation to form great hopes for its future.

We are indebted to the consulting engineers, Messrs. F. H. Medhurst, Page, and Lloyd, for the above description and loan of the photographs and drawings from which our illustrations have been prepared.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

*(Continued from page 230.)*

### Quadruple Winding Doubly Re-entrant.

Now in Fig. 12 we might (if there were room in the diagram) insert another winding exactly like that already drawn, with the spirals of the new winding occurring alternately with those of the old, just as we did in the cases of Figs. 1 and 10. This would give us 62 spirals upon the armature (in place of 31), a distance-pitch of $\frac{4}{62}$ (instead of $\frac{2}{31}$); and on the armature there would be two windings, each double, and each independent of the other. This additional winding would again double the number of commutator sections, and if the brush were wide enough would simply be placed in parallel with the original winding. We should describe this arrangement as a *quadruple multiple-circuit ring winding doubly re-entrant*, and we should denote it by $\omega\ \omega$. These symbols are in accordance with those used on page 187, and appear to explain themselves, since they denote two independent windings, each of which is in itself double. It will be noticed in the distance-pitch $\frac{4}{62}$ that the winding is quadruple, as shown by the numerator, and the number of spirals is 62, as shown by the denominator, and that these two numbers have a G.C.F. = 2, showing that the winding is only *doubly re-entrant*. Had there been 64 spirals with a distance-pitch of $\frac{4}{64}$, the winding would have been a quadruple winding four times re-entrant, and the armature would have been like Fig. 10, with two extra independent windings added.

### Drum Windings, Multiplex, Various Re-entrancy.

All this applies to ring armatures, and we will proceed to develop the corresponding drums. Using the same construction as before, we shall have 62 inductors as the equivalent of the 31 spirals, and just as in Fig. 12 we start from the spiral numbered 1 and pass to the next spiral but one, so in Fig. 13 (which shows the drum winding) we shall start from inductor No. 1, pass to one under a pole of opposite sign, and then return, not to No. 3, as in the case of a single winding, but to No. 5. In this diagram, where the inductors are numbered separately, the same arguments in favour of the number-pitches being odd apply as in the case of Fig. 8.

Following this scheme through, we find that arriving at inductor No. 61 we begin to pass into the second part of the winding, as shown by the connections 16 to 3, 3 to 20, and 20 to 7.

### Rules for these Drum Windings.

In the particular case illustrated the number-pitches are forward 17 and backward 13, and it will be remembered that in the case of a single winding $y_1 - y_2 = 2$. It is thus clear that one difference between a single and a double drum winding is that, instead of having $y_2 = y_1 - 2$, it becomes equal to $y_1 - 4$.

This rule will be seen to be exactly the same as that numbered 2A above—*i.e.*, $m$ has become in the general case not necessarily the number of *independent* wind-

Digitized by Google

ings, but merely the number of windings, where the word "winding" has the definition just given.

Of course, since the drum winding corresponds exactly to the ring, the re-entrancy will be governed by the same rule. It will, in fact, be the G.C.F. of $m$ and of the total number of spirals on the armature. Each spiral may be considered as consisting of two inductors with their connections, from which we get the rule as usually stated for multiplex multiple-circuit drums: *the re-entrancy is the G.C.F. of the number of windings and of half the number of inductors.*

In all other respects these multiple-wound multiple-circuit armatures, whether ring or drum, follow precisely the same laws as already laid down for the multiple-circuit single-wound armature. Thus the ring-wound armature of Fig. 10, if placed in a four-pole field, needs four rows of brushes, and in every respect fulfils the rules numbered 1, 2, 3, 4 on p. 114. Similarly, the arguments as to length of end connections, etc., used on p. 114 apply equally to multiple-wound multiple-circuit drums.

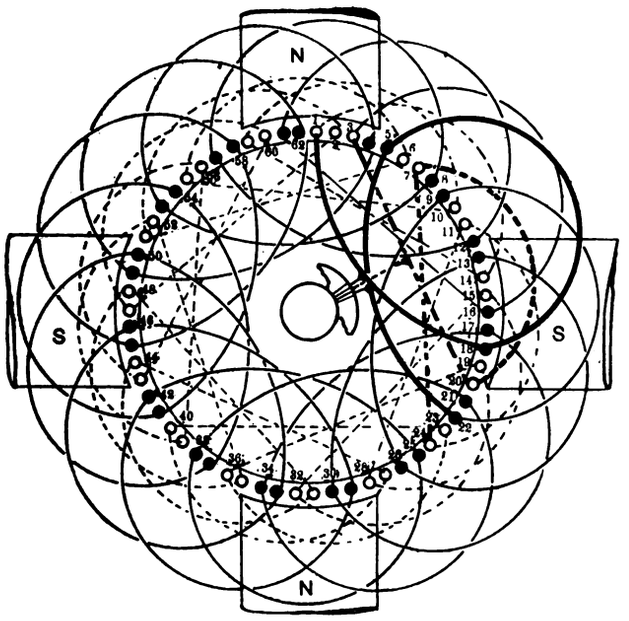

FIG. 13.

Now, as has been said, many writers on drum armatures draw a distinction between *lap* winding and *wave* winding. All the foregoing are lap windings, because having started from a certain inductor and crossed the armature, we *return* (or *lap* back) with a slightly smaller pitch toward the conductor from which we started. This "lapping back" is more clearly seen either by taking a small armature and actually winding a turn or two in place, or by drawing a development of a winding as is frequently done in other text-books. But we think that the system of constantly referring to the corresponding ring winding in the case of all multiple-circuit armatures, leads to a far better understanding of any particular problem than any system of projection or development.

We now append a *résumé* of the laws of multiple-circuit armatures, derived from all those rules previously developed.

**Laws of Multiple-Circuit Windings, Ring or Drum.**

Multiple-circuit armatures are of two classes, ring and drum.

*Ring Armatures.*—A ring winding consisting of $n$ spirals, or sets of spirals, placed evenly about the armature will be a single winding if the distance-pitch from one spiral to the next immediately in series with it is $\frac{1}{n}$ of the total circumference, whether the number of spirals is even or not.

If the *number of spirals is even* and the distance-pitch from one to the next immediately in series is $\frac{2}{n}$ of the total circumference, the armature will be double wound, having *two independent single windings*. It is, therefore, doubly re-entrant and expressed by the symbol o o. Or generally, if it have $n$ spirals having a distance-pitch = $\frac{g}{n}$ of the circumference, and $n$ is divisible by $g$, the winding will be a $g$-fold winding $g$ times re-entrant.

If, on the other hand, with a distance-pitch still equal to $\frac{g}{n}$, the number of spirals be not divisible by $g$, or only by some factor of $g$, say $h$, then we have a $g$-fold winding $h$ times re-entrant. All these windings will have as many sets of brushes as there are poles, and each pair of sets (positive and negative) adds $g$ parallel circuits to the winding.

In reckoning the distance-pitch, it must be remembered that the spirals are assumed to be uniformly distributed around the armature, this being a theoretical assumption. In many ring armatures the actual spirals are grouped in slots, but this need cause no confusion if, in arranging the winding, the smooth uniform armature is first assumed and the grouping arranged after.

Thus, if we have a four-pole machine with a ring armature consisting of 213 spirals, or sets of spirals, and the distance-pitch from one set of spirals to the next immediately in series is $\frac{6}{213}$ of the circumference of the armature, then:

There are two sets of positive brushes and two sets of negative brushes.

The winding is a sextuple winding triply re-entrant, expressed by the symbol $\omega\ \omega\ \omega$, because $\frac{6}{213} = \frac{3}{3} \times \frac{2}{71}$. Each brush must cover nearly six sections of the commutator, and the average number of circuits in parallel at any instant will be 24.

Of *multiple-circuit drum windings* we may say they are necessarily *lap windings*, and follow the same general rules as the ring windings above, being simplex, duplex, triplex, etc., according to the number of parallel paths per pole in the armature.

A duplex or multiplex winding may be singly or multi re-entrant, but this re-entrancy depends entirely upon the number of inductors.

There must be *in all cases* an even number of inductors, which must be a multiple of the number of commutator sections, and in the case of slotted armatures a multiple of the number of slots.

The number-pitches for any singly re-entrant winding must be odd, and consequently for each independent winding, or set of windings, the number-pitches *considered without reference to other windings upon the same armature* must be odd. From this it follows that, for instance, for a double-wound doubly re-entrant armature the number-pitches *may* be both even numbers; but generally odd numbers are taken.

The number-pitches for any number of inductors must differ by a number = 2 $m$, where $m$ is the number of windings.

The re-entrancy is = G.C.F. of $\frac{w}{2}$ and $m$, where $w$ is the number of inductors.

Digitized by Google

The forward number-pitch will usually be approximately equal to $\frac{w}{p}$, where $p$ is the number of poles.

The number of sets of brushes is equal to the number of poles, and each brush must cover a number of segments on the commutator greater than $m-1$.

No other formula whatever is necessary for these windings.

Taking as example an armature similar to the ring that we have just considered, we have a drum with 213 spirals or 426 inductors, the number-pitch (which is always more convenient in the case of drum armatures) is $y_1 = \frac{426}{4} = 107$ approximately, $y_2$ will be $= 107 - 2m = 107 - 12 = 95$. Thus it is a sextuple winding, and since the G.C.F. of $m$ $(=6)$ and $\frac{w}{2}$ $(=213)$ is 3, it is triply re-entrant, *exactly as the ring with 213 spirals.* If we wish to know whether an armature with this number of inductors might (with different end connections) be used for a six-pole field, we set about it as follows:

The forward number-pitch will be $\frac{426}{6} = 71$. If we arrange it as a single winding, the backward number-pitch will be 69; if as a double winding, it will be 67; if as a triple winding, 65. As a double winding the armature will be singly re-entrant, since there is no common factor of 2 and 213. As a triple winding it will be triply re-entrant, as 3 divides exactly into 213.

We have said that the forward number-pitch is an odd number approximately equal to $\frac{w}{p}$.

In the above instance we took it exactly $\frac{w}{p}$, but as a rule a better electrical result will be obtained if the mean number-pitch—*i.e.*, the arithmetic mean of the forward and backward number-pitches—is equal to $\frac{w}{p}$. This results in the forward number-pitch being a little greater than $\frac{w}{p}$, especially in the case of multiplex windings.

Thus, in the above example, the forward number-pitch would be better if taken 73 (instead of 71) with a backward number-pitch of 69 (instead of 67). This gives the mean number-pitch $= \frac{69+73}{2} = \frac{142}{2} = 71 = \frac{w}{p}$.

With the double winding $y_1 = 71$ and $y_2 = 67$ the mean number-pitch is only 68, but the other arrangement is better. The reason for this is as follows:

In a fairly uniform field with the ratio pole-arc ÷ pole-pitch large, if the mean number-pitch be less or greater than $\frac{w}{p}$ a certain differential action takes place, resulting in some inductors included between any pair of brushes generating an electromotive force opposite in direction to the current in that section of the armature. This may easily be seen by drawing out a drum armature with an extremely short mean number-pitch.

The greatest number of usefully active inductors is obtained always with a mean number-pitch $= \frac{w}{p}$. In some cases, however, the advantage gained by shortening the end connections more than counterbalances the disadvantages of the smaller mean number-pitch, particularly when the pole-arc is less than 80 per cent. of the pole-pitch.

An actual example, showing how the above laws may be applied in practice, may here be of interest.

A certain four-pole machine was required to give an output of 2 kw.—viz., 9 volts 220 amperes. On referring to the standard 2-kw. machine, it was found that there was room to fit a commutator large enough to carry the above current, and it was also known that the most favourable position on the magnetisation curve was where the number of magnetic lines passing through the armature per pole was $10^6$. The speed of the machine was 1,200 r.p.m., and the number of slots in the standard armature was 60. It was assumed that the electromotive force (allowing for fall of potential due to armature resistance, armature reaction, and possible belt slip) which must be developed by the armature was equal to 11·5 volts.

From the formula:

$$\text{No. of armature inductors} = \frac{\text{electromotive force} \times 10^8}{(\text{revolutions per second} \times \text{armature lines})}$$

we find that the number of armature inductors necessary will be 58, and the nearest number to this which is possible with the number of slots at our disposal is 60. Now, with a reasonable current density, the minimum size of solid wire which could be used would be No. 7 S.W.G., and the armature if wound with this gauge will have 60 inductors, a forward number-pitch of 15, with a backward number-pitch of 13, and a maximum number of commutator sections 30. But this small number of commutator sections will most certainly lead to serious sparking. We decide, therefore, upon a double winding giving double the number of sections. The winding becomes

| | |
|---|---|
| Inductors | 120 |
| Forward number-pitch | 31 |
| Backward number-pitch | 27 |
| Number of commutator sections | 60 |
| Gauge of wire (if solid) | No. 11 S.W.G |
| Re-entrancy double | symbol o o |

It will be noticed that besides the commutation advantages secured by this double winding, we have also a much easier gauge of wire to wind, and consequently a better distribution in the slots.

A double winding which is doubly re-entrant has always this advantage over a double winding singly re-entrant, that in case of an accident to one winding the other still continues to do its work.

This example only emphasises the value of a knowledge of these various winding schemes. When one becomes accustomed to dealing with all sorts of simplex and multiplex arrangements, it is astonishing to find how flexible a given machine may be in respect to the division of its output into volts and amperes The dimensions of the commutator, as a rule, are the limit, and the powers of any given design in this respect are much increased if the number of standard slots and sections is wisely chosen, thus enabling the same armature to be used for either a multiple or two circuit winding. This will become more clear after the study of the next chapter.

If after following the rules and explanations here given unforeseen difficulties occur in dealing with multiple-circuit drum armatures, we think such difficulties will immediately disappear if the course already recommended of setting out the corresponding ring winding be followed.

We shall, therefore, now leave these windings for what are termed *two-circuit or "wave" windings.*

## APPLICATION OF ELECTRICITY TO MINES.*

BY A. C. ANDERSON, STUDENT.

### PREAMBLE.

There is no longer any need to discuss the advisability of using electric energy for light and power in mining work. One can hardly pick up a technical paper nowadays without coming across a note to the effect that electricity is to be installed in some mine or that such an installation has established its superiority over other systems of driving. Steam is impossible owing to the prodigious condensation losses in lines of piping. Compressed air, electricity's only formidable rival for power, is still finding favour in some places for coal-cutting machinery, but even then the compressors are electrically driven, the compressed-air gear being purely subsidiary to, and a part of, the electric installation. Extensions are very easy on this system, as the compressors may be readily moved forward. At the Wharncliffe Silkstone Colliery, which has upwards of 800 h.p. in compressed-air plant installed, a change is being made in favour of electrical driving, as the efficiency of the present system is only about 30 per cent. In the case of the St. John's Colliery, Normanton, Yorks, also, electricity has proved more economical and convenient than compressed air. It has been argued that the exhaust from pneumatic motors has a beneficial cooling effect, but the proportion of the exhaust air to the main current flowing is so small as to hardly affect the temperature. The South Staffordshire Mines Drainage Commission, which commenced nearly two years ago to drive its surface pumps electrically, has found the results very satisfactory. It has reported that there has been less time spent in pumping, and that a further decrease is expected as steam is replaced more fully by electricity. Mr. Henry Hall (H M. Inspector of Mines for the Liverpool and North Wales district), in a report on mines and quarries issued by the Home Office, states that no accidents during 1903 were attributed to electricity, while rapid progress was made in its application to pumping, coal-cutting, and hauling. It would be a very excellent thing if the use of horses below ground could be entirely eliminated; they are most undesirable from the hygienic standpoint. Much has been done; both in the conversion of existing plant to electric driving and in the laying down of new installations. Satisfaction has been practically universal, and there can be no doubt that a great field has been opened for the enterprise of makers of electrical machinery for use in mines. In special circumstances, such as these, it must always be borne in mind that electricity is a "risk," like any other form of energy, and must be treated with due care. "Good work" should be the motto of an electric mining installation. The man who sacrifices efficiency and reliability to cheapness is courting disappointment and possible disaster. But given a sound, efficient system, carefully installed and properly handled, there cannot fail to be an appreciation of the advantages appertaining to electric transmission. Accidents occur, of course, but are almost invariably due either to bad workmanship in the construction of the plant or to carelessness on the part of those in charge of it, and are simply parallels of those which crop up in the use of any other system. Frequent reference is made below to the rules formulated by the Committee of Enquiry on the Use of Electricity in Mines, and throughout they are mentioned shortly as the "new rules."

### CHOICE OF A SYSTEM.

The mine owner or manager who wishes to instal electrical plant is immediately confronted with the question as to system. He wants the utmost efficiency and reliability, and these with a low capital expenditure and small maintenance costs. He will probably have received a large amount of contradictory advice as to the respective merits of direct current and three-phase alternating, and it is to be feared that the progress of electricity in mines is somewhat hampered by the inability of the non-electrical man to decide for himself on the best system for his special conditions. Opinion on this point is very divergent. Three-phase, though costly to produce, owing to the relatively poor power factor, is the cheapest to instal, given material and workmanship of equal quality.

From the results of experience it seems to have the greatest freedom from breakdown, with consequently reduced maintenance costs; moreover, it is very efficient in the generation, distribution, and transformation of energy in the main, but it is much hampered by line losses at low load and fall of pressure due to starting of motors. It is urged that by the use of induction motors sparking is entirely obviated, a point of paramount importance in fiery mines. Certainly the possible sparking at the commutator of the direct-current motor is got rid of, but there always remains the chance of a break in the mains or failure of the windings.

Moreover, the direct-current machine may be made gastight, and though sparking in such motors when driving coal-cutters may not be absolutely eliminated because of the excessive vibration, it is thereby rendered harmless. For haulage plants, motor-generators or converters are necessary with an alternating system, and batteries in the mains are out of the question. The small air-gaps in polyphase motors necessary for a good power factor necessitate the closest and most frequent inspection to prevent trouble. They are hardly suited for the drastic conditions of coal-cutting. Coal-cutters are also very disadvantageous to three-phase motors owing to the constantly varying load and consequent fluctuation in line pressure. This is sometimes so serious as to make it necessary to have separate plants for power and lighting. Such complication as this entails is very prejudicial to the employment of alternating currents. The excessive starting current taken by induction motors can only be made light of when the generating plant, etc., is relatively very large. With a well-designed squirrel-cage rotor a fair torque is obtained at starting, but the rush of the current is far greater than for a direct-current motor giving the same starting effort. A heavy line drop is thus inevitable unless a special expenditure is made in cables. Resistances cannot be done away with in connection with induction motors, but in place of a separate box they may be arranged in the rotor itself, or some pole-changing device may be adopted. This, however, will probably mean additional slip-rings and contacts. It would appear that fuses rarely blow on overloading of three-phase motors, as the windings exert a choking-coil effect, which keeps the current within certain limits. Variable speed with alternating motors is a most difficult problem, and proscribes their use to a large extent. It is an absolute necessity with fans, as the air supply must be capable of nice regulation. Moreover, one is rather restricted in the choice of speeds with three-phase motors. Alternating motors are very good when they can be run on constant load at constant speed, conditions met with in certain classes of pumping work, etc. By-passes can easily be arranged on the pumps to allow of gradual starting. A single-phase system, if it could be made practicable, would be most suitable for mining work. Three-phase alternating is quite unsuitable for locomotive traction in mines where trolley wires would be permitted, and no other form of alternating current is at present admissible for general use. It would be reasonable in some cases to transform from alternating to direct current by means of rotaries or motor-generators, more especially if the frequency of supply was 50, or thereabouts. For a large scheme, such as where several pits are fed from one central station above ground, an alternating system would unquestionably be adopted, at any rate for transmission. Continuous current is eminently suitable for large machines, such as winding and haulage gears, and large pumps, owing to great comparative ease of starting and regulating.

Speed variation is practically essential in most of the departments of mining work, and can now be accomplished very economically with direct-current machinery. In addition, a continuous-current system gives far better results on varying load (also an essential of mining work) than an alternating one. It seems to me that rather too much stress has been laid on commutator sparking. Arcing in switches is unavoidable in any case. It has been said—by Mr. Hall, I think—that the direct-current motor cannot be entirely enclosed, a fact cited as showing a distinct

* Paper read before the Birmingham Local Section of the Institution of Electrical Engineers.

Digitized by Google

advantage of the induction motor. There is no reason whatever why a continuous-current motor should not be completely enclosed if it is properly rated. For coal-cutting there is no motor giving a more efficient starting torque than the direct-current series type. When fuses blow with overloads on continuous-current motors driving coal-cutters, the men in charge, disliking the frequent stoppages, apparently have a knack of substituting larger and larger fuses, resulting finally in a burn-out of the armature, causing a serious waste of time. Unfortunately, this sort of thing is very difficult to put down. In the evidence given before the Departmental Committee on the Use of Electricity in Mines, it was stated on behalf of a company insuring electric plant at collieries, that 85·7 per cent. of accidents to dynamos and motors occurred in armatures or commutators, these mishaps being chiefly due to overloading. Mr. H. M. Hobart says that a continuous-current motor for coal-cutting would for a given output and speed have a smaller diameter, a much deeper air-gap, a higher efficiency, and a lower temperature rise than a polyphase motor for the same work. Further, the regulation would be much more suitable for lighting circuits.

The E.M.F. of an alternating system is much more flexible than that of a direct-current one; it is so easy to step up or down with static transformers, but it must be remembered that the frequency suitable for power is not suitable for lighting, a very important consideration, and one which by the introduction of further complication is likely to neutralise largely the copper economy incidental to the use of alternating currents. A direct-current plant for 500 volts, in the case of comparatively small plants, on the concentric system with earthed return is very good and elastic for all classes of work, but the choice of a system must really rest on the special circumstances of the particular case.

### Voltage, etc.

In the evidence rendered before the Mining Commission the majority of witnesses were agreed on limiting the pressure to from 500 to 600 volts at the actual workings. This seems really too cautious when compared with Continental practice. To quote one instance among many, at the Gneisenau Colliery an asynchronous motor receiving current at 2,200 volts is driving a pump situated 1,476ft. below the surface. The advantages of high-tension transmission in connection with mining are doubtful unless there is a large area to be supplied from one central station, necessitating considerable lengths of line on the surface. The new rules merely allow 650 volts as a maximum for motors or transformers up to 75 h.p. capacity. Consequently, when considering the question of single collieries with closely situated shafts, a 2,000-volt system, say, with its inevitable complication and increased first cost, owing to necessity for special insulation and transforming devices, is distinctly inadvisible, as not only will the economy in copper be swamped by the disadvantages named, but also a small proportion of the whole system will be worked at the high pressure. With a large and widely-distributed scheme, however, a three-phase high-tension system of transmission is admirable and absolutely necessary for the best commercial results; the considerable gain in copper much more than compensates for the extra apparatus necessary. With regard to the danger objections, it has been argued that the knowledge of the use of a high pressure tends to make men more careful. This would seem to be a somewhat neutral advantage. In alternating practice a low frequency of about 25 should be adopted for power circuits, and for lighting certainly not less than 45 to 50.

### Generating Plant.

In the ordinary way special consideration of this portion of the installation is hardly necessary, as it is nearly always placed on the surface, and is of the same nature as that in any other power station. But large size generators for mining work will most generally be required of the low-speed type, as colliery engineers much prefer to use horizontal engines for driving, as being machinery with which they are more familiar. High-speed engines of the type now almost universal in our central stations are, of course, perfectly suitable for mines, but it is somewhat difficult to persuade mining engineers to use them owing to the necessity of having a special staff of mechanics to look after them properly. Dynamos of over 250 kw. capacity would probably be coupled direct to the prime movers, machines of a less output being rope-driven. Without question all generators should be liberally rated. Machines intended for use below ground, including rotary transformers or motor-generators, have specially to be designed for ease of transport. They should be as absolutely reliable as possible, both electrically and mechanically, and should be subjected constantly to the most thorough supervision. The new rules have specially provided for the proper installation and care of the generating plant. It is to be isolated, an ample sufficiency of room is stipulated for each set, and all machines at a pressure higher than 250 volts are to have their frames efficiently connected with earth. It is to be hoped that there will no longer be any of that cramped huddling together of machinery which, unfortunately, so often characterises mining installations.

### Distribution.

The distribution system, comprising wiring and switch-gear, is from every point of view by far the most important factor in an electrical mining installation. The few isolated cases in which mining managers have actually condemned electricity as unsuitable have been almost entirely created by shoddy workmanship and thoughtless design in the wiring scheme. It is absolutely essential for the successful adaptation of electricity to mining that the system of wiring, with its controlling gear, should be as "solidly" installed as possible with the greatest care and the best material, due regard being paid in the design to any special circumstances. For continuous-current work concentric cables with the outer conductor earthed have proved very satisfactory, but the new rules prohibit earth circuits in the main, and the neutral point of a polyphase system may not be earthed until the district inspector of mines has been formally notified. All metallic sheathings and armourings should unquestionably be properly connected with earth. In an alternating system care must be exercised in the use of metallic armourings or the laying of cables in iron pipes, to minimise, as far as possible, inductive effects. Three-core cables should be used, not triple-concentric, and the algebraic sum of the currents must equal zero, as otherwise the inductive effects of the three cores will be unequal, and there will be a loss in efficiency. Moreover, in special cases, where for some reason direct-current and alternating mains have been laid in the same pit, great care must be taken to avoid the mutual effects of self-induction. The most favourable means of laying cables varies largely with circumstances. Bitumen-filled troughs are very good, but can very rarely be used in mining work without an additional armouring of the cables. Insulation consisting of paper or jute sheathed with vulcanised fibre or vulcanised bitumen with a double armouring of galvanised steel wires, is very good for difficult situations. Opinions, however, vary widely as to the protective covering to be adopted. Trailing cables for use with coal-cutters and portable drills present a very difficult problem. It is a hard matter to combine proper flexibility with sufficiently strong and reliable armouring. Some engineers use oak or teak casing in taking the mains down the shaft, others clamp with massive wooden cleats, and in the case of a brick-lined shaft, lewis bolts may be used to sustain the clamps. On the other hand, loose suspensions are often preferred, as giving the cable a better chance of withstanding mechanical shock. Joints in the cable are best made in connection boxes, which may, of course, at the same time contain switches or fuses. It is a moot point as to whether roof suspension is better than an arrangement on the sides or in the floor. It really depends on the relative strength and general suitability of these three alternatives. Certain it is that unless proper means are taken to prevent it, a fall of roof will probably break the cable suspended therefrom—a very dangerous possibility in a "gassy" mine. With a roof suspension some arrangement should be made such as that adopted at the Hulton Collieries, Bolton, where the cables are loosely suspended from the roof by

Digitized by Google

means of spun yarn, so that in the event of a fall no undue tension is put on another part. The floor would seem at first sight to be the best place for the mains, but it is frequently very uneven. It should not be possible for any circuit to be opened in the presence of an inflammable gas—that is to say, all boxes enclosing switches and fuses to be used in the dangerous sections of a mine should be gastight. Further, the switches are better immersed in oil. With regard to the general control of the scheme, it is best to arrange a disconnection box to ground cables at the top of the shaft and a distribution board with switches and fuses immediately at the bottom. Switchboards of the skeleton type, where there is really no "board" at all, are excellent for straightforward work, as every detail can be so readily inspected. Mr. Roslyn Holiday, of the Ackton Hall Colliery, makes his own switch-boxes for attaching to coal-cutter motors They are fitted with an accurately-machined cover and a cement joint. The switch handle works into a box through a gland. The voltage is 320, and there has been no sparking trouble. The more complex forms of gear, especially motor-starting rheostats, should be designed for the utmost reliability and ease of working. The movement of the switch arm over the contacts should be restrained in order to reduce the risk of an armature burn-out, an accident which should be rendered still more improbable by the use of proper protective devices in circuit with the machine. All metallic boxes, etc., should be earthed.

*(To be continued.)*

## SOME ELECTRIC LIGHTING TROUBLES WHICH MIGHT BE AVOIDED.

BY ALFRED H. MAYES.

Those who have had considerable experience of electric lighting installations can scarcely fail to have observed that the causes of breakdown or other trouble are comparatively few in number, and, consequently, the same class of fault presents itself again and again. Short-circuiting in lamp-holders is a prolific source of destruction to lamps, and frequently of far more serious damage. The cause is generally a stray strand from the end of the duplex conductor, which finds itself free from the remaining strands and manages to make contact with the opposite pole. The remedy for this trouble is simply to exercise more care in fixing the bunches of fine strands in their respective terminals. By far the most satisfactory plan is to burn off the insulation, which can be done without injuring the wires in the slightest degree, and then to tightly twist the strands into the semblance of a solid conductor, using the finger and thumb only for the operation. Should the pliers be brought into requisition for this purpose, the fine wires will certainly be bruised or broken, and the difficulty we are seeking to guard against will result.

The difficulty of obtaining a sufficiently high insulation resistance between the poles of the whole installation is not an unusual trouble, and is sometimes due to a little-suspected cause—that is to say, the employment of a cheap class of poorly-insulated duplex cord in some of the fittings. When one realises that the positive and negative poles of the system are closely twisted together, the necessity of high-class flexible cord is at once apparent, especially so in damp or exposed positions.

Serious loss and annoyance to users of the electric light is frequently caused by the "blowing" of sub- or main fuses. Whilst fully recognising the importance of not providing too much carrying capacity in fuses, it must also be borne in mind that if the capacity is cut too fine, that the premises may be plunged into darkness owing to a momentary and trifling increase in the supply voltage, and this frequently happens, causing much difficulty to the unfortunate consumer, who frequently has trouble in obtaining the services of an electrician to put matters right, especially should it occur late at night.

As anything tending to bring electric lighting into disrepute is strongly to the disadvantage of wiring contractors, attention to the foregoing hints will be amply repaid by increased satisfaction to users.

## INSTITUTION OF ELECTRICAL ENGINEERS.

The following candidates were elected at the ordinary general meeting on the 23rd ult. :

*Member.*—C. L. Edgar, Edison Electric Illuminating Company, Boston, Mass., U.S.A.

*Associate Members.*—J. Askew, 17, Moore-street, Preston, Lancs.; W. Briggs, 90, Camperdown-road, Scotstoun, Glasgow; J. W. Hadfield, Electricity Works, Castle-street, Barnstaple; D. Huntley, 70, Loveday-road, West Ealing; J. S. Morton, Corporation Electricity Works, Ashton-under-Lyne; G. R. J. Parkinson, 24, Wellington-road, Bilston; J. S. Peck, British Westinghouse E. and M. Company, Trafford Park, Manchester.

*Students.*—H. R. Ainsley, Faraday House, Charing Cross-road, W.C; E. Barraclough, 36, Hermitage-road, Crumpsall, Manchester; K. D. Bullpitt, The Mount, South Norwood-hill, S.E.; J. A. Cook, 12, Willowbridge-road, Canonbury, N.; H. Corney, 107, Jesmond-road, Newcastle-on-Tyne; T. C. Dunne, 5, Desmond-street, S. C.-road, Dublin; A. V. Ferguson, 6, Suez street, Warrington; H. O. M. Gammon, 25, Hawke road, Upper Norwood, S.E.; C. E. Garratt, The Uplands, Hagley, Worcestershire; E. W. Heathcote, Sunnyside, Erdington, Birmingham; L. B. Hewitt, Faraday House, Charing Cross-road, W.C.; C. Hobson, Kinrara, 93, Union-road, Clapham, S.W.; R. H. F. Houston, 1A, Ovington-square, S.W.; H. T. Jager, North View, Snakes-lane, Woodford Green, Essex; R. D. Jenner, 5, Bedford-street, Chorlton-on-Medlock, Manchester; D. Knowles, 8, Marshall-place, Cheetham, Manchester; T. S. Lacy, Saumarez, Sunninghill, Ascot; A. W. Lambourne, Bloxham House, Harborne, Birmingham; W. T. Massey, 4, Lee-grove, Salford, Manchester: M. Mercer, Bank Villas, Preston New-road, Blackburn; E. R. Myers, 6, Moreton-avenue, Stretford, Manchester; H. Pearce, Normanhurst, The Butts, Brentford; T. S. Pipe, South View, St. Saviour's road, Saltley, Birmingham; W. A. Pitts, 124, Cecil-street, Whitworth Park, Manchester; W. Rodger, 139, Morrin-street, Springburn; J. E. Roberts, 42, Albert-street, Rugby; H. M. W. Royce, 208, Plymouth-grove, Manchester; F. C. Russell, 303, Burton-road, Derby; C. E. Savage, Electric Power Station, Springsmire, Dudley; R. Savarimathen, Central Technical College, Exhibition-road, S.W.; R. Shaw, 7, Summerside-place, Bonnington, Edinburgh; T. M Taylor, Rosendale, Newcastle, Staffordshire; T. L. B. Westerdale, 13, Rectory-place, Woolwich, S.E.

## FORTHCOMING EVENTS.

FRIDAY, MARCH 3.

**North-East Coast Institution of Engineers and Shipbuilders (Newcastle).**—At 7.30 p.m., special meeting to consider the present Board of Trade Regulations for Certificated Marine Engineers, and to suggest certain modifications.

**Royal Institution.**—At 9 p.m., "Recent Advances in Wireless Telegraphy," by the Chevalier G. Marconi.

**Institution of Electrical Engineers (Leeds Section).**—Annual dinner.

**Junior Institution of Engineers.**—At 8 p.m., "Possible Improvements in Locomotive Practice," by Mr. W. Longland.

MONDAY, MARCH 6.

**Faraday Society.**—At 8 p.m., "Recent Developments in Electric Smelting in Connection with Iron and Steel," by Mr. F. W. Harbord.

**Society of Arts.**—At 8 p.m., "Internal-Combustion Engines" (Lecture IV.) by Mr. Dugald Clerk.

TUESDAY, MARCH 7.

**Institution of Civil Engineers.**—At 8 p.m., resumed discussion on Mr. R. W. Allen's paper, "Surface-Condensing Plants, and the Value of the Vacuum produced."

THURSDAY, MARCH 9.

**Institution of Electrical Engineers.**—At 8 p.m., report on experiments carried out at the National Physical Laboratory: "On the Effect of Heat on the Electrical and Mechanical Properties of Dielectrics," and "On the Temperature Distribution in the Interior of Field Coils," presented by Dr. R. T. Glazebrook, F.R.S.; "On Temperature Curves and the Rating of Electrical Machinery," by Mr. R. Goldschmidt.

FRIDAY, MARCH 10.

**Institution of Electrical Engineers (Manchester Section).**—At 7 p.m., annual dinner.

**Royal Institution.**—At 9 p.m., "The Structure of the Atom," by Prof. J. J. Thomson.

SATURDAY, MARCH 11.

**Junior Institution of Engineers.**—At 3 p.m., visit to the New Ritz Hotel, Piccadilly, to inspect the "cage skeleton system" of constructional engineering.

**Birmingham Electric Club.**—At 7 p.m., "Electric Lifting Machinery," by Mr. E. C. R. Marks.

**Royal Institution.**—At 3 p.m., "Electrical Properties of Radio-active Substances," by Prof. J. J. Thomson.

**Institution of Civil Engineers.**—On March 22, at 7 p.m., annual dinner at Merchant Taylors' Hall. Sir Guilford Molesworth, president, in the chair.

*Bound Volumes of* "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, July to December, 1904, now ready.*

## EVOLUTION IN ELECTRICAL DISTRIBUTION.

In the *London Gazette* of Nov. 25 last appeared the customary advertisement relating to application to Parliament for "power to establish stations and works for the generation and supply of electricity, etc., in the counties of Middlesex, Surrey, Essex, and Kent, and the administrative county of London . . ." This has been termed a mammoth power scheme, and it is. Its promoters have carried out a large scheme on the Tyneside, and we presume the experience thus gained leads them to the desire to tackle the Metropolis. The scheme may be good, bad, or indifferent; neither of these phases are we now going to discuss, much less to decide. The time, however, is ripe for the consideration of the subject generally, leaving special cases for the future. Assume for a moment that mammoth distribution schemes are in the natural order of things, and are better than aught that has gone before—that is, are more economical or efficient, for the product remains the same whether obtained from a large or a small installation. How is this advanced step in the evolution of the electrical industry going to affect what exists? Some of us, perhaps, are just old enough to recollect the inception of electric lighting, in the attempt and failure to light a street of Paris by battery power. For years after this lighting lapsed, except in a few instances for lighthouse purposes. Wilde, Siemens, and others worked to replace the battery by the dynamo, but electric lighting did not progress till Gramme on the one hand and Jablochkoff on the other provided, the one the machine, the other the candle. Then came a race of Titans. Who would be first, and who would succeed? The exhibition of 1881 at Paris opened the eyes of the world to the possibilities of the new system of lighting. There the arc was accompanied by the incandescent form of lamp, and experts had learned how simply and effectively the work could be done. We do not say the machines or the lamps were then perfect, but those who had studied the question knew the thing was possible, and that the experience gained in use would improve and hurry details towards perfection. The cry was, we can do it; let us do it; and the storm of opposition was roused. Gassites opposed the use of public money and laughed to scorn the possibility of electricity ever successfully contending with gas. The supporters of electricity were emphatic, but money to really test the matter was not easily forthcoming. We do not suggest that those who preached the perfections of gas were not in earnest, for history tells us that when in the early part of last century the attempt was made to introduce gas lighting, the opposition was just as violent and just as uncompromising. It may not be out of place to quote lines written nearly half a century ago about the opposition to gas lighting:

> "Only half a century since,
> Fifty years or so,
> Safely through our London streets
> At night, you could not go;
> Oil lamps, and Charlies,
> Strove with thieves and night;
> The public got the worst of it,
> And called for better light;
> When straight a cry was heard,
> 'No popery—no mass—
> Our glorious Constitution—
> No gas—no gas!'"

Time passed, money for small and for private installations was forthcoming—these invariably showed that the faith of electrical engineers was well grounded. At last, after herculean efforts, municipalities began to realise that companies or themselves would have to undertake the work of generation and distribution, for the demand for this kind of light was growing, and the multiplication of small plants was inefficient and uneconomical. We thus

Digitized by Google

come to schemes initiated and carried out for lighting whole districts. At the present time such installations run well into hundreds. The new departure practically argues even these schemes are too small, and that they should be replaced by larger schemes. Supply in bulk is the watchword. What of it? It must be remembered here that a step in progress is accentuated by the demand for power, and that this demand is rapidly overshadowing the demand for electrical energy for merely lighting purposes. The subject is a large one, and cannot be dealt with wholly in a short article. Take two points. Assume half a dozen towns, say within a circle of a dozen miles radius, each having its own electricity works, each having embarked £100,000 in those works. A promoter comes along and suggests a mammoth scheme to supersede the half-dozen. His contention is that he can supply in bulk to these centres cheaper than they can generate for themselves. Is it a necessity of progress that these half-dozen works go the way of the many little private installations, and be more or less consigned to the scrap heap, and the cost written off as a bad debt? Of course, the answer depends on simple arithmetical calculations which as yet have not been clearly proved. The other point we can refer to is whether really a mammoth scheme is more economical than a smaller one, though of considerable size. The answer to this is also an arithmetical calculation, which must be solved for each particular case, but we can at once say that in many cases the mammoth scheme would have no economical advantage over the smaller schemes. If the aid of Parliament is to be invoked, the greatest precautions should be taken to safeguard capital already involved unless it can be unmistakeably proved that the new step is sufficiently economical to counterbalance the loss involved.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### TELEPHONE PURCHASE.

SIR,—On Feb. 24 you were good enough to grant me space for a letter on this important subject, in which I demonstrated that (1) the proposed agreement meant the continuance of high rates till 1911 at least, without any indication as to what would happen thereafter, and (2) that it would make ducks and drakes of the existing municipal exchanges. I now propose to show that it is calculated to do the same with the Post Office itself. The maximum and minimum schedules of rates between which the company may oscillate at will constitute the ingenious device for compassing this end. The maximum schedule enables the company to maintain its high rates in non-competing centres; the minimum enables it to undercut the corporations and victimise the Post Office. One would imagine that the object of a minimum schedule would be to prevent the company undertaking unremunerative business to the injury of its successors, if not of its competitors. If this is not its object, what possible excuse can be advanced for such a schedule? Well, under the proposed minimum schedule the company is empowered to make contracts for two-party lines, and party lines serving three, four, or more subscribers for a first and last charge of ½d. for each outward call (inward calls being free), provided the receipts per subscriber do not fall below 20s. per annum. Thus a two-party line may produce £2 per annum, a three-party £3 per annum, and so on. No limit is placed on the length of such a line, which may extend to five or ten miles. Sir William Preece, in giving evidence for the Post Office before the Select Committee of 1898, said (Question 5,376) that on a five-party line it would be necessary to receive £4 per annum from each subscriber, or £20 in all, in order to make a profit of 12s. per subscriber per annum. That is to say, the working expenses would amount to £3. 8s. per subscriber per annum. He says that a yearly rental of £2, with 1d. calls amounting to another £2, are required to make such a line pay. Under the minimum schedule in the agreement the total receipts from such a line may be only £5, equivalent to a loss of £15 on Sir William Preece's figures. For a two-party line costing at least £40 to construct, according to Post Office figures, and costing at least £5. 5s. to work and maintain, the proposed income is £2! The Post Office charge for a two-party line is £3 per annum for each party, and 1d. per call (with a minimum of 30s. per annum), which gives them a certain revenue of 10s. in excess of Sir William Preece's estimate. The cheapest telephone system working is probably that of the States of Guernsey. The accounts of the Guernsey undertaking for 1904 show that the average working cost per telephone in the island was £3 1s. 11d. Supposing Guernsey let their telephones at 20s. per annum each, the handsome profit they would make would become a deplorable loss. So the company is to be free to build up a business of an absolutely ruinous character, and in 1911 to say to the Post Office, "These lines have cost us £40 each; please pay us back that amount." And the Post Office will be obliged to do so, less depreciation. Their first act will then no doubt be to give notice to such unremunerative subscribers to terminate contracts, but the taxpayer will have paid for plant which will lie derelict and useless. The prime intention of the minimum schedule is no doubt to enable the company to undercut the corporations, as I have already pointed out, but it also permits it to torpedo the Post Office itself. In 1869, when the telegraphs were purchased, the amount to be given depended on the mileage of wire existing at the date of transfer. There are officials in the Post Office to-day who were then employés of the various telegraph companies, and who still boast of the great deeds they performed in erecting hundreds of miles of useless wire between the date of agreement and the date of transfer for the Post Office to buy at three or four times its value. Similarly, when 1911 looms near the possibilities afforded by the minimum schedule for erecting plant will be sure to present themselves. Cheap telephones will have a tremendous spurt, and there will be a large if not choice assortment of 20s. subscribers, at £40 or £50 per line, for the Post Office to buy! But this is not all. Under Clause 9 (3A) *any* charges which the company may have in force at the date of the agreement are legalised, in spite of the schedules. In non-competing centres charges in excess of the maximum schedule exist; in competing centres charges below even the amazing minimum schedule are rife, all of which may be continued till 1911 and then handed over to the Post Office.

Other objections may and will be taken to this loose and ill-digested agreement, but consideration for your space deters me from touching upon more than one—I do hope that the clause referring to the company's staff will be reconsidered. Salaries have ruled very low, work has been hard, responsibility has been great. Hundreds have spent their best years—many count a quarter of a century—in the service. It is said—I know not how truthfully—that their own superannuation fund will not be available. But certainly, under Clause 8, the Post Office proposes to cast them adrift, or at least to give compensation, if at all, as a mere favour and not as an obligation. Surely this is not just and not what the British public would desire.—

Yours, etc, A. R. BENNETT.

## DIESELHORST-MARTIN TELEGRAPH AND TELEPHONE CABLES.

Following is a description of the Dieselhorst-Martin system of making dry-core telegraph and telephone cables. We understand that these cables are being used in very large quantities by the British Post Office, as it is recognised that only with cables made on this system is it possible to superimpose circuits with entire freedom from cross-talk.

The cores are made up of more than one pair by successive twinning operations, thus: (A) one insulated con-

Digitized by Google

ductor twisted with another insulated conductor to form a pair; (B) two pairs, made as in A, twisted together, to form a core of four wires; (C) two four-wire cores, made as in B, twisted together to form a core of eight wires; (D) two eight-wire cores, made as in C, twisted together to form a core of 16 wires; and so on. The length of lay is varied throughout, and a number of 4, 8, 16, etc., wire cores may be stranded into a cable, all being alike, or some of one and some of another size, while pairs or larger cores may be wormed between the main cores of the cable.

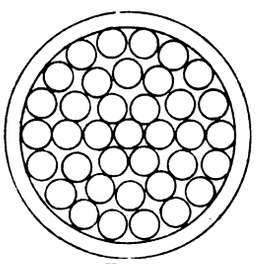

FIG. 1.

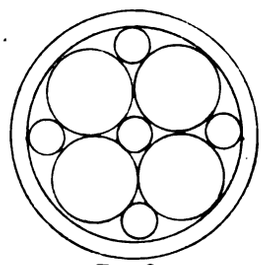

FIG. 2.

A 74-wire cable made up in the ordinary way is shown in section in Fig. 1. It is made up as follows: centre, 1 pair; first layer, 6 pairs; second layer, 12 pairs; third layer, 18 pairs—total, 37 pairs. Compare the above with the 74-wire cable made up on the Dieselhorst-Martin system (Fig. 2). This cable is made up as follows: centre, 1 pair; first layer, 4 16 wire cores; worming first layer, 4 pairs—total, 37 pairs. One of the 16-wire cores is shown in diagrammatic form in Fig. 3, which shows how the conductors are twisted together.

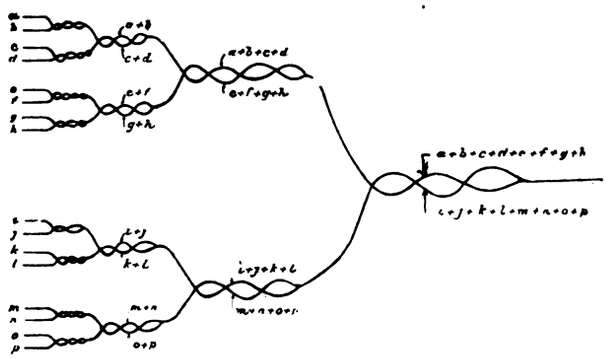

FIG 3.

If each conductor weighs 100lb. per mile, we may obtain from any one core of 16 wires the undermentioned loops: eight loops with conductors of 100lb. per mile, four loops with conductors of 200lb. per mile, two loops with conductors of 400lb. per mile, one loop with conductors of 800lb. per mile. It is important to notice that the loops of any one group will not interfere with the loops of the same or any other group, since they are twisted independently with different lengths of lay. The four 16-wire cores shown in Fig 2 might also be used as two loops of 1,600lb per mile each, or as one loop of 3,200lb per mile. It is found that, in any operation of bunching or grouping as described above, the increase in the electrostatic capacity is small compared with the decrease in the electrical resistance, the increase in capacity measured between wire and wire being only about 30 per cent.

The following table, showing the decrease in K.R. as the grouping proceeds, is compiled from the results of actual tests.

L = one conductor of the loop. $L^1$ = the other conductor of the loop.

| L. | $L^1$. | Resistance of loops in ohms per mile. | Electrostatic capacity per mile between conductors. | K.R. per mile of loop. |
|---|---|---|---|---|
| $a$ | $b$ | 11 | ·056 | 616 |
| $a+b$ | $c+d$ | 5·5 | ·073 | ·402 |
| $a+b+c+d$ | $e+f+g+h$ | 2·75 | ·098 | ·270 |
| $\left\{\begin{matrix}a+b+c+d+\\e+f+g+h\end{matrix}\right\}$ | $\left\{\begin{matrix}i+j+k+l+\\m+n+o+p\end{matrix}\right\}$ | 1·375 | ·135 | ·186 |

By the successive twinning system of constructing cable core, therefore, circuits of lower K.R. than one pair may readily be obtained, and because of the differential twinning of the components, the circuits so obtained will be free from overhearing. In addition to the advantage of being able to obtain loops of low K.R., the cores made by successive twinning may be used for superimposed circuit working without overhearing between the various parts. Fig. 4 indicates how 15 circuits may be obtained from a 16-wire core, and it will be seen that the 74-wire cable shown in Fig. 2 would provide for 65 circuits at least, as compared with 37 circuits if made up in the ordinary way (Fig. 1). The superimposing may take place over the whole length of cable as shown in Fig. 4, or over one part only.

The number of combinations obtainable is too great to be fully discussed here, but all of them consist of modifications or extensions of those shown. One other point may, however, be mentioned. In all telephone systems inconvenience is felt for want of circuits between one exchange

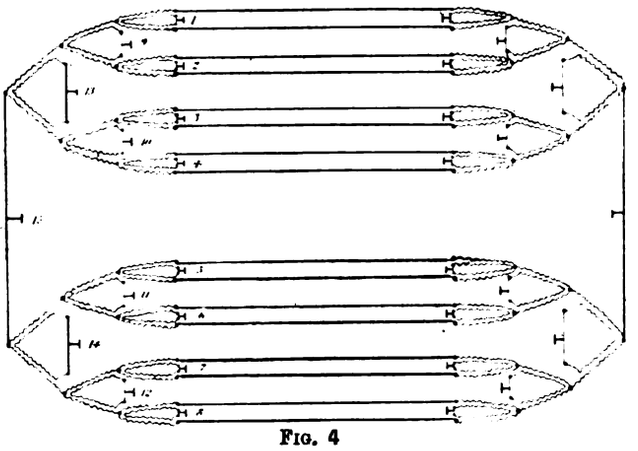

FIG. 4

and another for switching through purposes (called junction circuits). At present the number of these circuits cannot be increased without laying additional cables, but if a cable made up as described were employed between one exchange and another, additional circuits could be obtained by superimposing after each pair in the cable had been made use of.

Thus it is evident that, whereas in an ordinary dry-core cable the circuits to be obtained are the equivalents of the number of pairs of wires, the number of circuits in cables made on the Dieselhorst-Martin system is much greater than the number of pairs of conductors, and great economy may therefore be effected by the employment of such cables.

It remains to add that Messrs. Siemens Bros. and Co., Limited, 12, Queen Anne's-gate, London, S.W., to whom we are indebted for the particulars given herewith, are the manufacturers of these cables; also the sole licensees for the same.

## SOME NOTES ON THE RUNNING OF A PRIVATE LIGHTING AND POWER PLANT.*

BY P. T. BLISSET, ASSOC.MEMB.

(*Concluded from page 269.*)

The cost of maintenance for turbo sets should be very little, the biggest item, perhaps, being new brushes and the renewal of the commutator, say, every four years. It may be safely said that the cost of repairs and oil together for them is not one-sixth of that for the Willans engines.

Any comments on the running of Mather and Platt generators are not necessary, as no complaint is ever heard concerning them. The middle-wire current is dealt with by two balancer sets, which were made up of old 210-volt generators.

The power wiring has been done chiefly by the staff on the works, and some time ago was carried out with lead-covered and armoured cables fixed by means of teak cleats. Although this style of wiring gave comparative safety, it was impossible to pull the cables quite straight, and it was difficult to bend them neatly round sharp corners. Much of the armoured cable was afterwards put into wood troughs and covered with a teak capping, the smaller cables being put into specially heavy pitch-pine casings. For the heavier cables, say $^{37}/_{16}$, the wood troughing with cleats every 2ft. makes a very good job, and if the troughing is well coated with shellac inside to keep

* Paper read before the Dublin Local Section of the Institution of Electrical Engineers, Feb. 9.

Digitized by Google

moisture from coming through, the arrangement has been found to stand well under very trying conditions, braided cables only being used. Braided cables have been drawn into galvanised iron screwed tubes, but the drawing-in part is very difficult with cables of over $^{7}/_{16}$. There is a great temptation to thread the pipe fittings over the cables and then screw them up, resulting in the cables being twisted and badly damaged.

coming in and going out near the axis of the hinges need have no slack in them. A diagram (C) of a pair of fuses and meter are shown which illustrates this idea. When anything went wrong in a circuit, it was very difficult for anyone not knowing the geography of it to find where all the various fuses were.

As distributing boxes, with their many more or less weak connections, is where trouble is often found, the importance of

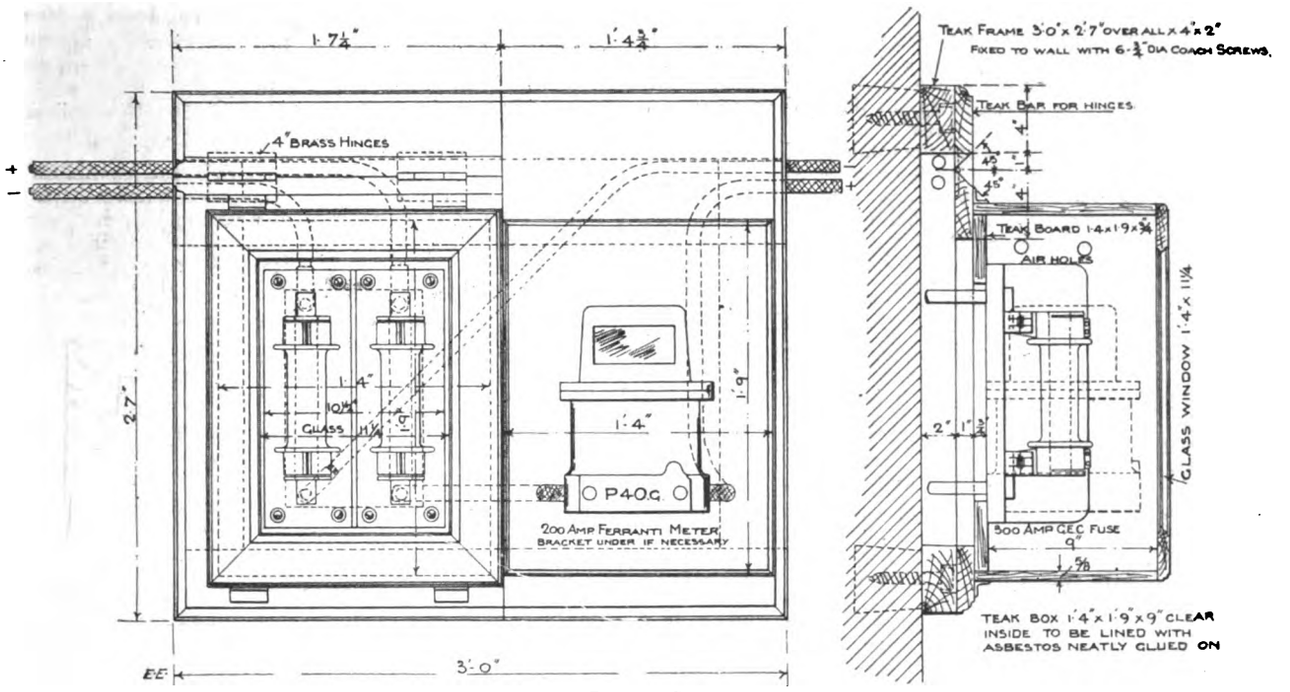

DIAGRAM C.

The draw-in system, perhaps, exists more in theory than anywhere else, and though a large variety of junction and draw-in boxes are supplied, it has not been possible to arrange the circuits so that the cables could be drawn in unless it was an easy run. Long straight runs for cables have been fixed to porcelain cleats—an old arrangement which is very satisfactory.

The cable fixings inside and out of factories are generally the worst-looking job about the place, and as their safety is of

very ready access to both front and back should be recognised. Cables sweated into cable eyes (sometimes badly) have been known to fall out from the melting or softening of the solder. No weight of cable should, therefore, be allowed to hang on a cable eye into which it is only sweated. In a running plant, where so much depends on the distributing system, these small details are of more importance than is thought by those who design small electrical gear.

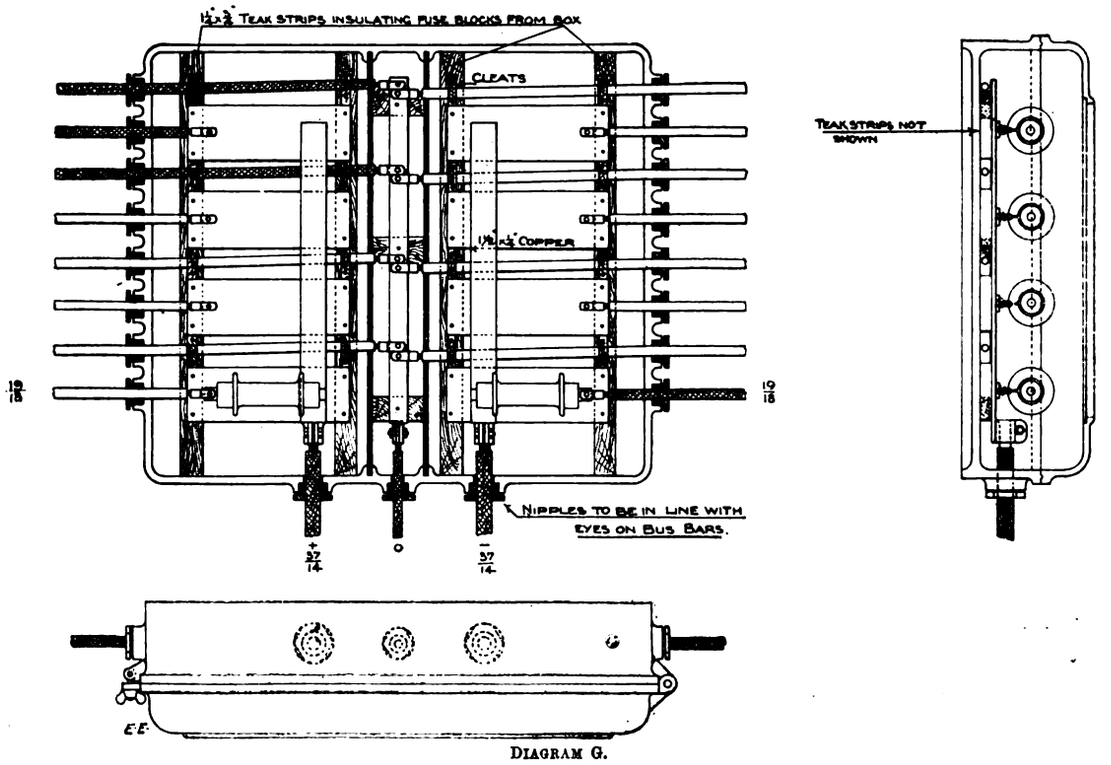

DIAGRAM G.

the greatest importance, carrying, as they do, the energy of the whole concern, it is surprising that more attention has not been bestowed upon them. When cables come to a distribution or fuse box, they should preferably be brought into it direct on to front-connected switches or fuses, or, if back connected, should be brought in at the side of a frame on which is mounted a door, hinged horizontally, and carrying the fuse or switch gear, so that the back connections are accessible, and the cables

Small gear as supplied in the ordinary way by manufacturers is usually too light for the usage it has to put up with. Screws, etc., are generally put where they cannot be tightened up without taking off much covering. Highly-polished hexagon nuts, etc., are fixed where a spanner cannot be got on them, and results in the pliers being used. Brassfinishers' nuts, being of various sizes, do not usually fit ordinary Whitworth spanners. Little troubles like the above result in many connections becom-

Digitized by Google

ing loose, and there is no reason why electrical apparatus could not be as standardised as far as these details go as ordinary engine work.

Of the various types of fuses tried, the switch type with the porcelain handle appears to be the best. The hollow handles should, however, be lined with plaster or asbestos; porcelain handles with no lining being extremely dangerous to anyone putting in a fuse with "a short" on the line, which is likely to burst the handle, the arc inside the handle causing it to expand suddenly. The damper type of fuse cannot be seen when blown, and in the larger sizes the holders are burst. Copper wire appears to be the best to use for fuses except for very small currents. In the majority of switch fuses the spring contacts are easily bent, and no provision is made to prevent the fuseholder from falling out when the contact springs are bent.

The number of first-class motors for continuous current on the market at present, makes the selection of suitable motors easier than a few years ago. In the matter of efficiency there is not much to choose between any of the good makers. The importance of the mechanical design of most of them has been well considered, some, however, being rather badly arranged for changing the armature. It is not much good to arrange the top half of the motor to lift off in a few seconds and find that it takes 10 minutes to disconnect the shunt. There is no reason why the shunt connections should not be made automatically when the top is lifted on, as is done in some of the motors.

There is a great difference in the winding of armatures, some being very much more difficult to get a coil out of than others. Certainly the best kind is the "former" wound type for repairing, the individual coils being bound together very hard. Some makers of armatures use very soft coils, and not only does the insulation get rubbed off the wires, but the coils are very difficult to get into the slots. A great many breakdowns of armatures are due to the wires flying out at the commutator end, where they are sweated into the bars. They should always be bound down with piano wire binding, or some better connection provided. Some breakdowns are due to careless handling in putting the armatures into the carcases, but this can only be expected when it is such a difficult job in some cases. The unfortunate part of this kind of fault is that it takes time to develop. As sometimes the spindles of motors get bent or damaged, it is a great advantage to have the coil mounted on a sleeve which can be drawn off the spindle. A weak point in the insulation of armatures is at the outer end of the commutators, as there is generally a thickness of mica only between the end of the commutator and the spindle.

TABLE E.—Efficiency of Shunt-Wound Motors.

| Motor makers. | Horse-power. | Revs. per min. | Commercial efficiency per cent. at Full. | ¾ load. | ½ load. | ¼ load. |

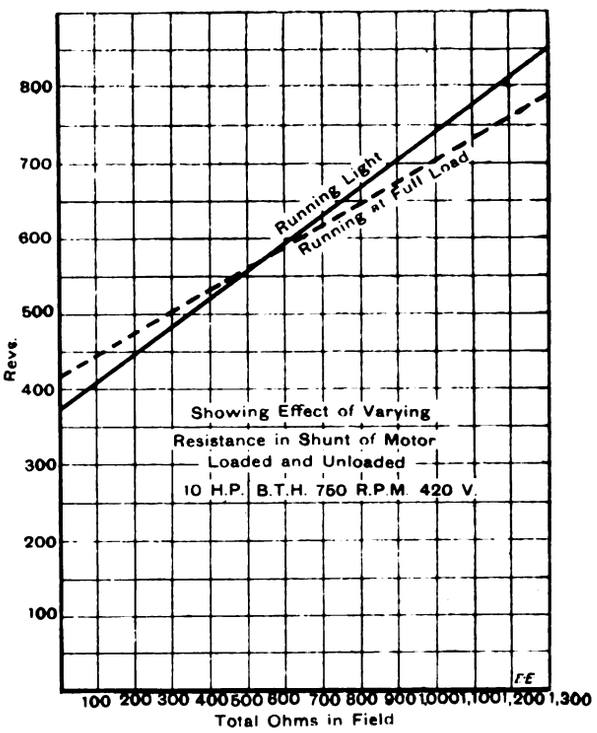
Practically all the motors used are of the enclosed type and coupled direct on to the machinery they drive. Of course the slow-speed motor is an expensive one for its power, but there is no doubt that it is a more satisfactory arrangement. As there are 204 motors in use, varying from ¼ h.p. to 15 h.p., with a total horse-power of 1,363, it speaks well for electrical driving, under the worst conditions when it can be said that there are rarely more than two or three armatures under repair. Spare armatures are kept for all motors, and a breakdown causes little delay. The majority of the motors being well above their work, breakdowns from overloading rarely occur. There is no serious loss in efficiency when working under full load, and with small motors particularly it pays to put in a much larger motor than actually required, as this is about the only way of preventing breakdowns on small motors. A table (E) is given which shows the results of the tests made on some of the motors used, from which it will be seen that the efficiencies do not decrease much at the smaller loads. It will be noticed also that the efficiency of the high-speed motors is not quite as good as the moderate-speed. The temperature rise inside the motors varies from 32deg. F. in the slow and moderate speed motors to 88deg. F. in the highest speed. Great temperature rises in motors affect the speed by heating the shunts, weakening the fields, and raising the speed. This difficulty, however, is got over by taking a few series windings round the fields to increase their strength.

As speed regulation by means of altering the field strength is becoming common, a curve showing an experiment on a 10-h.p. motor will perhaps be interesting (see Curve F). It will be noticed that the alteration in the speed is much greater when running light than with a full load. The upper part only of the curve was found by experiment, about one-third of the lower part being produced from the upper. Twenty-five-horse-power motors are being installed with a variation in speed of 275 revolutions per minute to 600, one half being done by shunt regulation on the 420-volt circuit and the other half on the 210-volt circuit.

The best form of brush gear is found to be the parallel frame arrangement with a spring across the diagonal, which is certainly better than the gear provided with a rectangular slot hole in which the carbon slides. Unless considerable pressure is put on the brushes, they are liable to stick, and too much pressure causes great wear of the commutator.



CURVE F.

Motor-starting gear is, perhaps, one of the most troublesome arrangements—far more than are the motors. The makers of this kind of gear have not brought their branch up to the same standard as the motor builders. Resistances are seldom properly divided. Insulation from the frames is often not good, and generally the resistance coils are not heavy enough to stand the starting current long enough. The starters adopted are made to stand the starting current for about a minute without injury, so that if the circuit breaker or fuse goes whilst starting, the motor can be started again without waiting for the resistance to cool down. The ordinary man does not think of waiting for cooling, and often results in the burning out of small capacity resistances. The asbestos tubes used for winding the coils on are liable to get moist, and when wet there are leakages to the frame, from which bad shocks are to be had. Many of the handles for switches and starting levers are ridiculously small, and, as they have fairly rough work to do, should be made much heavier. The card-wound type of resistances used were very unfortunate in breakdowns, and have nearly all had to be replaced by other types. The insulating material being porous absorbed moisture, which caused much of the trouble. Some of the resistances supplied were insulated with a kind of paper tarred over, and which set fire when the resistance warmed up.

Circuit breakers were used on the distributing mains and many of the motor panels, but it was found that a very small short would pull out a large circuit breaker: they were therefore replaced by fuses. Circuit breakers on motor panels were not satisfactory, as they did not always come out at the right time, and sometimes got stuck if they were not used for some time.

All motor panels are provided with double-pole switches, fuses, and an ammeter with a full-load mark on it. The ammeter should be of the dead-beat type, and is a great advantage at starting, showing if anything is wrong with the motor or the gear driven. It is important that all connections to starting gear should be accessible from the front,

Digitized by Google

and that the starters can be changed quickly. The complete panels should be enclosed in a case to keep all contacts clean, especially the starting contacts, which, when dirty, sometimes cut the greater part of the resistance out at one jump. Coal dust on the slates has sometimes caused an arc between two terminals. As starting gear for motors is responsible for the greater number of failures, their importance should be appreciated, and though much has been done recently in making starting gears more substantial, there is room for great improvement in the designs.

Although the wiring question has been discussed for years a satisfactory system has not been found. Much thought has been put into the perfecting of the various tube systems, and no doubt these are very good where there is no moisture, which is the greatest enemy to wiring systems. Unfortunately, the tubing systems have been a failure when there is much moisture or variation of temperature. Brazed steel conduit was used, and it was found that moisture collected in pockets, due to condensation, which soon destroyed the insulation of the wires. The enamelling of the tube was not good enough to resist corrosion for long, and rusted through in some cases in less than two years. The "draw-in" system for light wiring may be possible in dwelling-houses, but where the runs are round joists and girders or other difficult runs, it is practically impossible to draw the wires in, and consequently the tubes have to be slipped over the wires. Tubing unless fastened on to girder work very carefully is likely to get loose and the ends of the tubes cut through the insulation. Galvanised screwed tubing has been used with fairly good results, but is expensive and has the condensation trouble. The steel tubing used in offices and dwelling-houses was in some cases installed by local contractors, whose men made sure that the wires could never be drawn out of them, perhaps with the object of covering up some very bad work which has begun to show itself. A large quantity of concentric wiring was installed, and, according to the claims made for it, the system would have been a perfect one for wet situations. Unfortunately, this, too, had to be replaced by entirely new wiring. The concentric wires were lead sheathed, but could not have been perfectly watertight, as faults are continually occurring, as many as six or eight in a length of a foot. A fault soon burns itself out, blowing the fuse which is replaced, and goes on for another day or two, where another fault occurs, perhaps quite close to the first, as when burnt out the insulation test is fairly good, but has left a large hole in the wire somewhere. As this sort of thing going on continually is very dangerous from a fireman's point of view, it was decided to abandon this system. The watertight distribution boxes used sometimes got filled with water, which was soon boiled and fuses blown. A peculiar thing with these fuses was that if one blew several more would do so at same time, probably due to induction in the line supplying the box.

For moderately dry situations a specially heavy pitch-pine casing (fixed by carpenters) has been very successful. The capping was screwed on to the casing at the outside instead of the middle as usual. In this way a fairly tight joint can be made if thick paint is used to make a joint. Casing can be finished off very neatly, and wiring carried out on this system has given little or no trouble. Switch and fuse distributing boxes used with casing should have all the switches in one row, and the complete box hinged at its upper horizontal edge, so that the wires coming down from the casings come straight on to the terminals at the back without any slack or crossing wires, the hinges being provided to allow of easy access to the back of the board and prevent the usual entanglement of slack wire.

The cleat system of wiring for light has been tried with success, and although this form of wiring is not looked upon favourably by insurance companies, it has proved itself up to now to be as safe as the other systems, and has certainly many advantages. It can be done very neatly, and in much less time. Unfortunately, porcelain fittings for this kind of work have not been obtained, and various makeshifts have been used in consequence. Junction and cross-over boxes could be made, but the prices are prohibitive for small quantities. There appears to be a good opening for manufacturers to take this matter up, and an extensive use of wiring on porcelain cleats would be likely to be made, especially for factories. The accompanying diagram (G) of a fuse box for cleat wiring gives an idea of how such a system as this could be made very reliable for wet situations.

The result of experience with lighting of large areas broken up with columns, joists, etc., has led to the conclusion that groups of incandescent lamps are more economical to run and require less attention than enclosed arc lamp lighting, arc lamps being always a source of more or less trouble, especially in steamy places. Perhaps arc lamps of the open type may be successful for street-lighting, but for interior lighting on 210-volt circuits the losses in the lamp are so great that probably a new three-watt incandescent lamp can show as good an efficiency as a small arc lamp. If the cost of trimming and maintenance are considered, the cost of arc lamp lighting may come out more than incandescent.

In conclusion, I have to thank the firm, who do not wish their name made known, for allowing me to bring these notes before you, and trust that much of it will not be too commonplace for your discussion.

## TRADE NOTICES AND NOVELTIES.

### Battery Telephones.

The accompanying illustrations (Figs. 1 and 2) show respectively a battery telephone table set suitable for offices, hotels, etc., and an intercommunication table set. Particulars of both these sets are included in a handy little catalogue of battery

FIG. 1.—G.E.C. Battery Telephone Table Set.

ringing telephones and accessories just issued by the General Electric Company, 71, Queen Victoria-street, E.C. They are quite new, and will doubtless be appreciated. We need not enumerate here the further contents of the catalogue in detail. Suffice it to say all the instruments listed have been specially designed to meet the demand for cheap indoor and short-distance apparatus. Only such accessories are included as are most suitable for use in conjunction with the instruments illustrated, so as to prevent the possibility of wrong selection.

FIG. 2.—G.E.C. Intercommunication Battery Table Set.

A comprehensive set of diagrams showing how to connect up the instruments is added at the end of the catalogue.

### Electric Cranes

Messrs. Royce, Limited, Manchester, have recently issued a revised and enlarged edition of their catalogue of electric cranes and auxiliary apparatus. This is a very excellent production of its kind. Fig. 1 herewith is a reproduction of one of the numerous illustrations which the catalogue contains. It shows a "Royce" electrically-driven transporter, adapted for dealing with loads of from 10cwt. to five tons. Two motors are provided, one for each of the motions of hoisting and travelling.

Digitized by Google

This particular transporter is designed for running on curved tracks, and is fitted with swivelling bogies for that purpose. The hoisting motion is fitted with an automatic electrical brake, which can be released by hand from the driver's cage, and loads lowered without current when necessary. An overwinding safeguard is also provided, and the gearing throughout is machine-cut. For the rapid handling of material and conveyance of

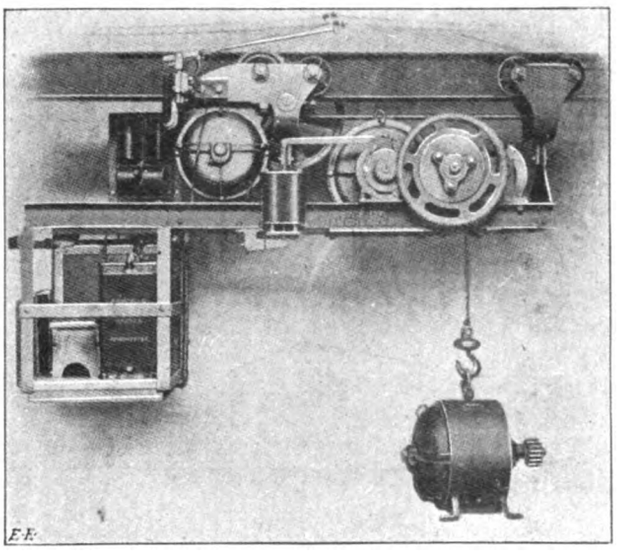


FIG. 1.—Royce 5-ton Electrically-Driven Transporter.

the same from one point to another, transporters of the above type are extremely useful.

## ELECTRICAL EXHIBITION.

A meeting of station engineers, under the presidency of Mr. W. H. Patchell, was held on Monday at the instance of the National Electrical Manufacturers' Association, when the proposed electrical exhibition, to which we referred in our issue of the 17th ult., was considered. After Mr. Patchell had explained the position, the following gentlemen were elected to represent supply stations on the executive: Mr. W. H. Patchell (Charing Cross and Strand Company), Mr. Cunliffe Owen (Metropolitan Electric Supply Company), Mr. Sydney Dobson (St. James's and Pall Mall Company), and Mr. Sydney Baynes (St. Pancras Borough Council).

The Municipal Electrical Association has been asked to nominate a representative, so that the supply station interests will be served by three company and two municipal men. The promoters suggest that the supply stations shall contribute £3 000. Already some 70 firms have promised to exhibit, and excursion trains will be run from the provinces.

## PERSONAL.

The King has been pleased to appoint the Hon. Alfred Erskine Gathorne-Hardy to be a commissioner under the Railway and Canal Traffic Act, 1888, in the room of Viscount Cobham, resigned. Mr. Alfred Gathorne-Hardy takes the position of chairman of the Light Railway Commission (unpaid) in the place of the Earl of Jersey, resigned.

The Southend Town Council have appointed Mr. J. Milton, A.M.I.E.E., mains superintendent and general assistant, as temporary assistant electrical engineer for six months, at a salary of £150 per annum.

The Newcastle City Council have appointed Mr. Ernest Hatton, manager of the Salford Corporation tramways, as manager of the Newcastle tramways, in place of Mr. A. E. Le Rossignol, resigned, at a salary of £700 a year.

Mr. W. H. Brown, of 7, Lothbury, London, E.C., has been elected a director of the London United Tramways, Limited.

The Grimsby Public Lighting Committee have increased the salary of Mr. Channon, chief assistant, from £150 to £175, and that of Mr. Horton, chief clerk, from £120 to £150.

The Ayr Tramways Committee have appointed Mr. William Grant, tramway manager, Rotherham, manager of the Ayr Corporation tramways in succession to Mr. Frederick Coutts, at a salary of £200 per annum.

## APPOINTMENTS VACANT.

**Depot Foreman,** Exeter Corporation Tramways. Salary, £2 a week. Applications by March 10. See advertisement.

**First Assistant Electrical Engineer,** City of Wakefield. Salary, £150 per annum. Applications by March 14. See advertisement.

## POST OFFICE ENGINEERING DEPARTMENT, LONDON.

The second annual dinner of the above department was held on Friday, Feb. 24, 1905, in the Victoria Hall, Hotel Cecil, Strand, Mr. J. Gavey, C.B., M.I.C.E., engineer-in-chief of the Post Office, again presiding. The guests of the evening included Mr. H. Babington-Smith, C.S.I. (secretary); Mr. J. C. Lamb, C.B., C.M.G.; Mr. J. Ardron; Mr. A. F. King; Sir Robert Hunter; Mr. S. C. Hooley, I.S.O.; Mr. J. C. Badcock, C.B.; Captain R. H. H. Boys, R.E., D.S.O.; Dr. Walmsley; Mr. A. M. J. Ogilvie; Mr. J. W. Willmot; Mr. W. Bosomworth; Mr. G. Morgan; Mr. A. W. Heaviside, I.S.O.; and Mr. W. J. Etheridge; the company numbering about 200. Lord Stanley, the Postmaster-General, who was attending his Majesty's second Court of the season, was prevented from being present.

After the loyal toasts had been duly honoured, **Mr. Lamb,** in the absence of Lord Stanley, in proposing the "Engineering Department," said: As your chairman has told you, gentlemen, it is the unavoidable absence of the Postmaster-General that procures me the honour of addressing you to-night and proposing the toast of the evening; but while it procures me this honour it leaves me in some embarrassment, because Lord Stanley has not handed me his notes or given me any indication of what he was going to say; and, therefore, I am afraid I shall be but a sorry substitute. But I am sure that I am speaking for him truly when I say that he cordially wishes you every prosperity, and that he regrets his absence quite as much as you do. If envy were a permissible thing, I think I might envy you engineers your association with those brilliant men, past and present, who have done so much to improve and facilitate and quicken communication in the world; who have invented instruments of the most marvellous kind for simplex, duplex, quadruplex, and multiplex telegraphy; for high-speed telegraphy; for telegraphy which will produce your writing at the other end; and for telegraphy which will turn Wheatstone signals into Roman characters. But I think my envy might go further, because I see opening before you another field that you did not dream of years ago—a field in which you are to be associated with the men, both past and present, who have worked wonders for the transmission of power and energy in the world and for rapid transport. In the past you have been associated with men like Morse and Hughes and Cooke and Wheatstone and Graham Bell and Marconi; and now you find yourselves associated also with men like Watt and Stephenson, and with those who are now applying electricity to the things to which those men applied steam. Well, I think we might all envy you engineers when we see this wonderful development of your field of industry. It is a development not merely in the outside world, but it is in the Department itself; your sphere within the Post Office is being extended and enlarged; you are ceasing to be telegraph engineers; you are becoming more and more general engineers. But I think I appeal to your hearts more when I say that you are all proud to be telegraph men, not telegraph engineers, but telegraph men; and here I detect no envy in my mind, because I am one of yourselves. I am a telegraph man. I began in the Post Office in 1864, I became a telegraph man in 1868, and have been one ever since, and I have given my whole heart and soul to telegraphs, and am proud of it. Well, gentlemen, speaking to you as one of yourselves, I say that we telegraph men have a sphere which is larger than that of any other body of men in the world. It is larger than that of the soldier; it is much larger than that of the ordinary Civil servant. We are not limited to our own Empire. We go out in friendship and harmony to every corner of the world, and we find people ready to receive us as brothers. It has always been to me a pride and consolation that no matter where I go I find men who understand me. Even when I speak in broken language they apprehend what I mean and are ready to welcome me, and this is the case with telegraph men all over the world. Now, gentlemen, when I was young and unwilling to go to bed, my father used to say to me

"Oft' fitted the halter, oft' traversed the cart,
And often took leave, but seemed loth to depart."

That was a little thing which was said about gentlemen who were sent to Tyburn. I am rather in the position now of the gentlemen who were carted off to Tyburn. They generally made a last dying speech and confession, and that is what I am doing. It is an accident—the accident of the absence of the Postmaster-General—that procures me the honour of making this speech; and in that respect I differ from the men who went to Tyburn, because it was generally not an accident which procured them the honour—the accident in their case generally happened afterwards. But, accident or no accident, I am very much in the position of those gentlemen, for I don't suppose I shall have the pleasure of being present at one of these dinners again, and therefore I take the opportunity of wishing you from the bottom of my heart an affectionate farewell. I now ask you to drink—you gentlemen here who do not belong to the engineering department—I ask you to join me in heartily drinking the health of the engineering department.

**Mr. Gavey,** in responding, said: Gentlemen,—In the first place I know that I am only voicing your feeling of regret when I say how sorry we are that the Postmaster-General is unable to be here to-night. Lord Stanley, by his soldierly frankness, has endeared himself to all with whom he has come into contact, and I am sure we feel that there is something missing in the evening's programme. On the other hand, I may say on your behalf that we are very proud to see the permanent chiefs of great departments and the heads of so many branches around our table to-night. I think that for the benefit of the service as a whole the heads of the great administrative departments of the Post Office, and the hands and brains that they direct in the shape of executive officers, should come into contact whenever it is possible. In a great service like the Post Office it is only on special occasions like

Digitized by Google

this that such community is possible, and I hope it is a pleasure to the administrative heads to meet you to-night; and I am sure it is a pleasure to the executive officers to see those gentlemen enthroned on high, of whom they can only form a definite opinion on occasions like this. At a meeting of this kind they see that these great officers are, after all, men with passions like themselves, and I hope when some of you gentlemen, disappointed that suggestions of yours or appeals of yours are not acceded to, that you will not come to the conclusion that they are rejected by beings who are stocks and stones, but by sympathetic officers who look carefully and considerately into everything you put before them. Now, gentlemen, the thread of my thoughts has been diverted into a painful channel, by what I can only assume to be our friend Mr. Lamb's species of valedictory address. I may say that I listened to the latter part of his speech with considerable pain and with very great regret. Those who, like myself, have been associated with the telegraph service for very many years, can hardly look back to the period of State control without the recollection of seeing the magical letters "J. C. L." at the bottom of papers. As time has gone by my appreciation of Mr. Lamb's talents, of his extraordinary knowledge of the telegraphs, not only of this country, but of the whole world, has grown day by day. In fact, I think that he is absolutely the supreme authority on telegraphs throughout the whole of the world. If the time has arrived, or is about to arrive, when he bids farewell to the service, I hope, and most sincerely hope, that he will not bid farewell to this company or to its successors. I trust that for many years to come we, or our successors, may be favoured with his presence at meetings of this kind, when we can look back to the past with pleasure and look forward to the future with appreciation. Now, gentlemen, we have adopted the practice, or, rather, we started the practice last year, of briefly reviewing what we had done during the year, and I think it may not be considered inappropriate if I continue that practice. I am glad to say that our progress, both telegraphically and telephonically, appears to be very satisfactory. From the telegraphic point of view, I think I may say that the Post Office telegraphs is certainly in the forefront, or if that may be considered too ambitious, I may say that it is not behind any other telegraphic service of the whole world. I have had the pleasure from time to time of meeting the higher officials of the telegraph administrations both in Europe and America, and they have all said to me that we had nothing to learn from them. Now, if you accept that statement with a grain of salt, and if you discount it to allow for the natural courtesy of the host to the guest I think we may say, or rather we may assume, that we are certainly not in the background, but in the front. The telegraph administration of this great department has always done everything to foster and encourage progress. In the course of the last year or two a number of experimental trials of the most advanced type of telegraph apparatus have been carried out. We have, in addition, forwarded that great work of the underground telegraphs of the North, and at the present times our lines may be said to be complete to Carlisle, and to be on the verge of completion to Glasgow. In other words, during the last few years we have laid something like 30,000 miles of underground wire to steady and to make absolutely free from all climatic disturbances the great trunk-line service of the country. This work is to be continued so long as our paymaster, the Treasury, finds the funds. I am glad to say that those funds are provided for next year, so that for one year at least this progress is absolutely sure. In the matter of the extension of the London telephone service, which perhaps more closely affects many of the gentlemen who are here present, I am glad to say that we have made very solid and very steady progress. You will all remember that it was in February, 1902, that the first London exchange was opened with 250 subscribers. I find that on Feb. 22 of this year we had joined up 25,138 stations, and in the present year of that number 8 803 stations were provided. In the case of the trunk-line service, the adjunct to the local service, or perhaps I should say the local service is the adjunct to the trunk-line service, if we speak of the importance of the relative services and not of their numbers, we have to record continued growth. In 1897, shortly after the Post Office had acquired the trunk lines erected by the Telephone Company, and had commenced the extension of the service throughout the country, there were 47,855 miles of trunk line in use. At the end of last financial year there were 102,752 miles erected, and the Post Office is steadily erecting from seven to eight thousand miles of trunk wires every year. Now, gentlemen, I come to another point which no doubt has exercised your minds more or less, and in which you have, no doubt, felt a considerable amount of interest. The agreement between the Post Office and the National Telephone Company has now been laid before Parliament, and you are, no doubt, generally acquainted with its contents. You will have observed, of course, that the final acquisition of the company will take place in 1911. As an old warhorse, who sniffs the battle from afar, I may say that, personally, I might have wished to have had my little share in that great transfer, but the fates and the wisdom of our chiefs have decided otherwise. So far, however, as you are concerned, and more especially the younger men that I see around me, I should like to offer a word of suggestion and a word of advice. I have a settled conviction that we are only on the threshold of this very great enterprise. The magnitude of the work that you gentlemen will have to carry out in future years is perhaps only appreciated by a few. To give you an illustration of what I mean, I should like to refer to the abnormal growth of telephones that has taken place in the United States within the last few years. For instance, I was in America in 1898, and in New York at that time there were 26,031 telephone exchange stations, the term station, of course, being well understood by all. I have recently received a letter from the general manager of the New York telephones, who tells me that at the end of the year 1904 that 26,000 had increased to 140,000 stations in New York, and you will bear in mind that New York proper is not the greater New York, including Brooklyn and New Jersey. It is a little bit of an island 10 miles long by about three miles broad, with a population of about two millions. Again, taking the report of the American Bell Telephone Company, I find that in 1899 throughout the United States they had 465,000 subscribers' stations. In 1904, after an interval of five years, they had 1,525 000 stations. Now, in this country the rapid growth of the telephone is of comparatively recent date, and the problems which you gentlemen will have to solve in the future will increase in magnitude as the square of the number of subscribers, and not as the numbers themselves. Think, gentlemen, what you will have to consider in the year 1911. It will not be a question of intercommunication between 100,000 subscribers—it will be a question of intercommunication between a quarter of a million, with probably the possibility of having to provide intercommunication between half a million 10 years later. It means that you will have to apply the highest technical and scientific knowledge that it is possible for men to obtain in order to do this work in a satisfactory and an economical manner, and what I want to suggest to you gentlemen, if you will not consider it an impertinence, and if you will not think that I am acting too much as the schoolmaster, is that before the transfer takes place you should fit yourselves, by keeping abreast with all the technical knowledge of the age, to take the position which you ought to occupy when that great transfer takes place. We have now in preparation at headquarters a species of technical summary of the theoretical principles on which telephony is based, and the lines on which the work ought to be done in the future. With the consent of our chiefs, I propose to have this printed and issued shortly, and I invite your careful attention to it, not by any means as a complete work, but rather as an index, a sort of direction post, pointing out the various paths in which you should carry out your investigations. Gentlemen, I am afraid I have rather transgressed the etiquette of an after-dinner speech. I ought to have been light and airy—I have been heavy and ponderous, but I hope the occasion justifies the character of the address.

**Mr. J. W. Woods**, the superintending engineer of the metropolitan central district, in proposing the toast of "The Visitors," said: Mr. Chairman, Gentlemen,—The members of the Post Office engineering department are always pleased to gather together in this quiet and homely way, and, like hospitable Britons, we like to have our visitors with us to taste our frugal fare. I confess that we are sorry that one visitor, Lord Stanley, has been unable to be with us to-night; we should have liked to tell Lord Stanley how much we appreciate him as Postmaster-General. As engineers, we realise that everything human, as well as everything material and physical, has its limitations—the higher the altitude the more the stress of the storm is felt, and consequently the more the structure needs to be stayed. The Postmaster-General's position is exalted, but is well supported. We have already heard, and heard with regret, that Mr. Lamb will soon be leaving the service. I realise, and I am sure you realise, that the service will lose a very true friend when Mr. Lamb goes. As I have said, the Postmaster-General's position is buttressed and supported by secretaries, and we are very thankful, indeed, that Mr. Babington-Smith, the secretary, has again come and graced our meeting. We realise the arduousness of his position, and how difficult it must be to meet every necessity of such a position, but, again, Mr. Babington-Smith is well supported by his secretaries (Mr. Lamb, Mr. Ardron, and Mr. King), whom I see before me, who are all supporting, very definitely and loyally, a chief who is worthy of their support. I am almost afraid, gentlemen, to mention another name, but there is an illustrious gentleman opposite me—Sir Robert Hunter. Naturally you would expect that I should be very diffident, indeed, in saying anything about so legal a gentleman, but we do sincerely thank Sir Robert Hunter for being present, and we realise that in Sir Robert Hunter the Postmaster-General is well supported on the legal side. Before me I see also Mr. Hooley, the controller of stores. Now, gentlemen, I think you will agree with me that there are many present who have looked upon the controller of stores as almost supernatural — an abstract being who has been prayed to and prayed for many a time, and about whom many things, wise and otherwise, have been said. It is a great boon for the younger members of the engineering branch to have seen the genial personage, Mr. Hooley, and to realise that he is a gentleman such as they scarcely expected. We honour Mr. Hooley because he has brought a department, on which every other department has to lean to a certain extent, to a state of great perfection. We are delighted to see Mr. Hooley at our table, and we thank him for the hard work that he has done since he has been the head of the stores department. I am delighted also to see Mr. Badcock, representing the postal side. What should we do without the postal side of our department? We should scarcely be able to live, and we are thankful to see Mr. Badcock here. I see also my good friend, Mr. Preston, on the other side. We have to rub shoulders very often with Mr. Preston. Do not imagine for one moment that there is friction. We rub shoulders in the sense that we each put our shoulder to a wheel, and thus make the whole thing go. If you will allow me, I should like also to refer to two grey-headed veterans, Mr. Heaviside and Mr. Fleetwood. We greet them most heartily, and we trust that when our time comes to "sit down" we shall look as hale and hearty as our two friends. I think you will agree with me, gentlemen, that I have demonstrated my inability to adequately express your views and your thanks to the visitors. What I have lacked in eloquence I have no doubt you will make up in heartiness in drinking the toast of "Our Visitors."

**Mr. Babington-Smith** said: Mr. Chairman, Gentlemen,—I have to thank you very warmly both for the way in which the toast of "The Visitors" has been proposed by Mr. Woods and received by you, and also for your genial hospitality to us to-night. I thank you on my own behalf, and I thank you on behalf of my colleagues who are here as your visitors to-night, and on behalf of those distinguished strangers who are also your guests. I may mention specially Dr. Walmsley, to whose instruction the engineering service of the Post Office is much indebted. I may mention Mr. Murray. I am not sure whether I ought to call him a visitor, for I am glad to say that now

Digitized by Google

he has at least one foot in the engineering service of the Post Office; and I speak also on behalf of the representatives of the distinguished firm of Siemens, to whose co-operation in telegraphic matters the Post Office is also so much indebted. Gentlemen, it is a very great pleasure to all of us to be here as your guests to-night, and to take part in what Mr. Woods has described as this family occasion. Your service, gentlemen, is sometimes maligned. I have heard it said sometimes that you obstruct the streets. That is a calumny to which I have never paid any attention—except this evening, when for the first time I was somewhat inclined to echo it. On my way here to join your gathering my cab was stopped—I don't know for how many minutes—by a block in the traffic, and when at last I was able to move on I recognised certain familiar brown structures which I have heard described as "wigwams," and I recognised that your work, or perhaps I should say our work—for I am afraid I cannot divest myself of a share in the responsibility—had caused obstruction in the traffic. But these, gentlemen, are passing incidents to which we pay no attention. You belong to the party, not of obstruction, but of progress. Your chairman has spoken of progress in the past. The engineering service of the Post Office is, if I may so describe it, a fine growing boy; and with growing boys the only difficulty is that they outgrow their clothes so fast. Mr. Woods mentioned Mr. Hooley with respect, tempered, shall I say, with awe; and I should like to say incidentally that the only complaint I have to make of Mr. Hooley is that he outgrows his clothes so fast. We bought recently a large site in the centre of the City—the Christ's Hospital site—consisting of more than three acres of land. When we had bought this land, Mr. Hooley came to us with a mild request to be allowed to put down a few stores in a corner of the site. I passed there a fortnight afterwards on my way to the Post Office, and I found the whole three acres covered with enormous drums of cable. How long they are going to remain there I don't know; but I think that when we want to build on that site we shall have some trouble with Mr. Hooley. Gentlemen, the history of your service in the past has been a history of progress. That progress has been watched over from its infancy, I may say, by my colleague, Mr. Lamb. He assisted at the birth of the telegraph service of the State; he has watched over its growth, and though to our very great regret we are soon to be deprived of his great talents and his long experience, he may rest assured that his name will always remain associated with the great service of which he has for so long been a distinguished member. The record of the service, gentlemen, has been a record of progress in the past, and it will be a record of still greater progress in the future; of progress upon the present lines, of progress in the development of new inventions. Your chairman has mentioned an agreement recently concluded, which, if it is confirmed by Parliament, as I hope it will be, will mean that the telephonic service of the Post Office will see a very great development some years hence. Not all of us, but I hope a great many of us, will assist at that development, and I should like to take this opportunity of saying that if that agreement has been made upon sound lines, if in settling the many technical points which arose in the negotiation of that agreement any satisfactory solution has been reached, it is in a very great measure due to the keen scientific and large-minded insight with which your chairman advised the authorities of the Post Office on those technical problems. Gentlemen, I have only once more to thank you very heartily in the name of your visitors for your kind welcome to-night, and to wish all prosperity in the future to the engineering department of the Post Office.

The musical programme, under the direction of Mr. H. J. Hoggarth, was of an exceptionally high order.

# LEGAL INTELLIGENCE.

## ACTION FOR DAMAGES DISMISSED.

In the King's Bench Division Mr. Justice Ridley and a special jury tried an action to recover £1,000 damages from the East Ham Council for injuries alleged to have been received by the breaking of an electric wire while the plaintiff, Henry Neal, a cycle maker, of 19, Meanley-road, Manor Park, was travelling on an electric car.

Mr. McCall, K.C., and Mr. Blaiklock appeared for the plaintiff. Mr. Montagu Lush, K.C., and Mr. Higgins represented the defendant Council.

**Mr. McCall, K.C.**, in opening the plaintiff's case, said it was a difficult and complicated one. On Sunday morning, Sept. 13, 1903, plaintiff left his house with his nephew to go to Woolwich. They got on a car which was not covered, and sat on the extreme seat on the left-hand side on the top. While they were travelling towards Beckton one of the overhead wires snapped. The broken wire struck plaintiff on his head and shoulder, burnt a hole in his cap and coat, and gave him a shock. The iron trolley pole also struck him. The immediate effect was to make him dizzy, and for a time he was unable to realise what had happened. He returned home and was laid up. Later in the day he took some tea, was then seized with a violent sickness, and a doctor was sent for. In his youth plaintiff had a slight accident to his left eye, but the effect was not serious. Since the accident on the tramcar his right eye was almost useless, and his eyesight had gone from bad to worse. He had been quite unable to carry on his business, and he had had an attack of locomotor ataxy, which prevented him from earning his living. There was no hope of plaintiff ever being able to follow any trade in which good eyesight was essential, and there was little hope that in the future he would be able to use his limbs without great effort and without great pain.

The Plaintiff bore out his counsel's statements, and corroborative evidence was given.

**Mr. Lush, K.C.**, in opening the case for the defence, said it was a painful thing to have to say, but the whole of plaintiff's case was a preposterous tissue of exaggerated mis-statements. The plaintiff at the time of the accident was sitting on the back seat of a car crowded with passengers, when a wire broke and fell upon the shoulders of the travellers. The only man who complained of being hurt was the plaintiff. Another passenger called admitted no shock or injury, only a coat burnt, for which she was compensated. The whole of plaintiff's case rested entirely upon his own evidence. If he had not been telling the truth in that court, it was perfectly consistent that he had not been injured at all. Plaintiff said he was hurt by a pole, but his doctor said his injuries would be caused by a wire. The plaintiff and his wife said that his system was so shattered that he could not walk, and only limped. A witness would be called to prove that he had seen plaintiff since the accident walk to his business. It was childish nonsense for the plaintiff to say he could not walk. Counsel then adverted to the fact that plaintiff had not produced any books in support of his assertion that his business yielded a profit of some £400 per annum.

Several witnesses having been called on behalf of the defence to prove the facts, and technical and medical testimony having been tendered, the jury returned a verdict for the Council, with costs, the judge expressing his complete concurrence.

We are glad to see that the Council succeeded in resisting this claim, which excited serious criticism at the hands of the expert witnesses for the defence.

## ARC LAMP PATENT.

After a protracted hearing, judgment has been delivered in the case of the Jandus Arc Lamps and Electric Company *v.* Arc Lamps, Limited.

The dispute centred around a patent granted in 1893 to Mr. L. E. Howard for an invention to prevent the carbons from being rapidly consumed, which the defendants were alleged to have infringed. The grantee enclosed the two carbon points in a very small glass cylinder, which was as nearly as possible hermetically sealed, so as to materially increase the life of the carbon. The patentee found that the nearer he could get the glass to the carbon the longer the life of the carbon. This idea was further developed in an amended complete specification.

The main defence was lack of novelty.

**Mr. Justice Kekewich**, in summing up, said that the essentials of the patent were a glass envelope, small but not too small, and joints, tight but not too tight. The specification indicated 3in. diameter or less, while in practice the plaintiffs had found 4in. better. The defendants had worked this divergence for all it was worth, but his Lordship held that the smallness was sufficiently indicated. Howard, unlike Beardsley, had recognised the value not only of tight joints, but of small globes, and his patent was, therefore, valid.

Judgment for plaintiffs, with costs.

## NORWICH CORPORATION v. NORWICH TRAMWAYS COMPANY.

The company's appeal from the decision of Mr. Justice Phillimore, who awarded the Corporation £53. 13s. 10d., as reported in this journal at the time, for street repairs, came before the Court of Appeal last week, when counsel argued points of law.

# COMPANIES' MEETINGS AND REPORTS

## KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING.

The eighteenth ordinary general meeting was held last week, Colonel Crompton presiding. Particulars of the report appeared in our issue of the 17th ult.

The **Chairman** said that the Company's high position as regarded economical management was maintained, but they were still groaning under the heavy load of municipal rates. The outlook for the future was satisfactory. The price which the Company charged their consumers depended entirely upon the number of hours during which the plant could be utilised. So long as electricity was only adopted for lighting purposes, the use of the plant was limited to about 12 per cent. of the total hours of the year. In other countries, notably in America, the electric lighting companies were able to utilise their plant during the daylight hours to a very considerable extent by supplying electricity for motors and for uses other than lighting. The Board and the staff had been fully aware of the great advantages which would follow, both to the public and to the shareholders, from the increased use of electricity during the daytime; and no effort had been spared to get a day load. There were signs that the domestic uses of electric power were on the increase.

The report was adopted.

## LONDON UNITED TRAMWAYS.

The third ordinary general meeting of this Company was held on Tuesday at the offices of the Company, Mr. Charles T. Yerkes (chairman) presiding.

The **Chairman**, in moving the adoption of the report (which we published last week), first reviewed the financial aspect of the undertaking, and then dealt with the affairs of the Company generally. The Company are doing all they can to provide double lines wherever possible, and have already derived benefit from the conversion of some of the single lines. The company's working has now been standardised so as to secure the maximum of economy consistent with efficiency. Since the last meeting the line from Southall *via* Hayes and Hillingdon to Uxbridge, and also the connecting line from Hammersmith-broadway *via* Askew-road, have been successfully put into operation, and the

Digitized by Google

result of the working of these lines since June last has fully realised anticipations. The directors believe that a very large development of traffic will now rapidly take place along the fine stretch of country between Southall and Uxbridge. The directors are concluding contracts for the building and equipment of the authorised extension of the system in Kingston, Surbiton, the Maldens, and Wimbledon, and between Brentford and Hanwell. The work of construction will be proceeded with forthwith, and the lines, it is expected, will be completed and put into operation during the course of the year. These lines will link up important centres of population, putting them in through communication with the rest of the Company's system, and with the London County Council's electric tramway system at Tooting. Mr. Yerkes concluded by moving the following resolution: "That the directors' report and statement of accounts be received and adopted; that the payment of the dividend on the preference shares having been made, and, being hereby confirmed, a final dividend of 6 per cent. per annum be paid on the ordinary shares for the half-year ended Dec. 31 last, making 6 per cent. for the year, and that such dividend be payable on and after the 4th prox."

**Mr. Clifton Robinson** seconded.

A **Shareholder** expressed the view that the reserve fund was inadequate.

The **Chairman** replied that the amount was only the nucleus of a reserve fund.

The report was unanimously adopted.

Mr. W. H. Brown (of Messrs. Speyer and Co.) was elected a director in the place of Mr. Samuel White.

**Mr. Yerkes** intimated his intention of resigning the chairmanship, owing to other engagements, but he will continue on the board of directors.

A resolution was carried authorising a maximum of seven instead of five directors.

An extraordinary general meeting was then held, and the following resolution passed: "That the following Bills be, and the same are hereby, approved, subject to such additions, alterations, and variations as may be made in the Bills by Parliament, and approved of by the directors: (1) 'A Bill to extend the time limited by "The London United Tramways Act, 1901," and "The London United Tramways Act, 1902," for the construction of tramways and the acquisition of lands.' (2) 'A Bill to empower the Great Northern, Piccadilly, and Brompton Railway Company to construct new railways in extension of their authorised railways and for other purposes.'"

## NERNST ELECTRIC LIGHT.

The adjourned general meeting of shareholders of this Company was held on the 26th ult. at the Westminster Palace Hotel, under the presidency of Mr. Bernard M. Drake, chairman of the Company.

The **Chairman** stated that the business before the meeting that day consisted of the appointment of a director and the election of auditors. As shareholders were aware, the two names before them for the directorship were Mr. Wallis-Jones (the director retiring in rotation) and Sir H. Seton-Karr, who was put forward by Mr. Oppenheimer. After a lengthy discussion, Mr. Oppenheimer's amendment was defeated, and Mr. Wallis-Jones re-elected.

The retiring auditors (Messrs. Deloitte, Dever, Griffiths, and Co.) were unanimously re-elected.

**Mr. Langham Reed** proposed a vote of thanks to the chairman for the way in which he had fulfilled the arduous task of presiding at that meeting.

**Mr. Zusman** seconded the motion, and the vote having been accorded, the proceedings terminated.

## NATIONAL TELEPHONE.

The half-yearly meeting of this Company was held in London on Tuesday, Sir Henry Fowler, M.P., presiding. Particulars of the report appeared in our last week's issue.

The **Chairman** reviewed the financial results, and then dealt with the arrangement just entered into with the Postmaster-General. As soon as the agreement had been ratified, he said, the directors intended to take the opinion of counsel as to what were the real legal rights of the various classes of debenture stock and shareholders. It was their intention to spend a great deal more capital, and to extend their business as far as possible. When the agreement became operative the directors would at once consider the wisest course for raising the capital and the mode of raising it. Shareholders might depend on it that the Board would see that they got 20s. in the £ for all their capital in 1911.

A **Shareholder** asked: Will the compensation we are to receive from the Government result in the return of the whole of the capital of the Company?

The **Chairman**: You ask me the most important detail of all, and as the matter is *sub judice* I cannot answer it. However, we have done the best we could.

The report was adopted.

## YORKSHIRE ELECTRIC POWER.

The fourth half-yearly meeting of the Yorkshire Electric Power Company was held on Monday at the Hotel Metropole, Leeds, Mr. A. G. Lupton presiding. Particulars of the report appeared in our last week's issue.

The **Chairman**, after reviewing the position, remarked that it was very dangerous to prophesy, but the Company had made a beginning in supplying their customers, and were entering into contracts at what, to any one accustomed to lighting prices, seemed exceedingly low prices, which, however, he believed were no smaller than other companies were asking. They had settled agreements with customers for supplying current to the extent of 900 h.p. They were about to supply three local authorities—Pudsey, Liversedge, and Mirfield—they had other negotiations in hand, and he had the greatest confidence that by the end of the year they would at all events have doubled the supply of 900 h.p. already agreed upon. The directors had under consideration a scheme for hiring-out motors.

**Mr. Robert Armitage** (Lord Mayor of Leeds) seconded the motion, which was agreed to without discussion.

Messrs. H. A. Earle, H. C. Embleton, and W. P. J. Fawcus were re-elected directors, and Mr. Ernest Crewdson was reappointed as one of the auditors for two years.

## CHELSEA ELECTRICITY SUPPLY.

The annual general meeting of this Company was held at Winchester House last week. Mr. J. Irving Courtenay presided. Particulars of the report appeared in our last week's issue.

The **Chairman** said that the equipment of the generating station at Alpha-place had been completed; but to provide for the further generating power required, the building of a section of a new generating station in Manor-street, adjoining the present Alpha-place station, would be carried out during the present year.

The report was adopted unanimously.

At an extraordinary meeting which followed the Company was authorised to introduce a Bill into Parliament for the extinction of the founders' shares.

Subsequently, Mr. W. Reginald Davies presided over a meeting of the holders of founders' shares, who agreed with the resolution passed at the extraordinary meeting.

## BAKER STREET AND WATERLOO RAILWAY.

At the half-yearly meeting of this Company, held under the presidency of Mr. T. J. Hare, the report, of which we gave particulars in our issue of the 17th ult., was adopted.

## CAMBRIDGE ELECTRIC SUPPLY.

The thirteenth annual meeting of this Company was held at the registered offices in Cambridge last week, Mr. D. Munsey, chairman of directors, presiding. The report, of which we published particulars last week, was adopted.

## W. T. HENLEY'S TELEGRAPH.

The report for 1904, to be presented at the meeting on the 6th inst., states that the net profit is £46,521. After payment of directors' and auditors' fees, debenture interest, and income tax, and making the usual allowance for depreciation of buildings, plant, machinery, etc., there remains £38,263, making, with £27,585 brought forward, a total of £65,848. The directors have transferred £1,000 to the debenture redemption sinking fund, and recommend a dividend on the ordinary shares at the rate of 15 per cent., including the interim dividend of 5 per cent. paid on Sept. 1 last. These payments will, together with the preference dividend, amount to £39,337, leaving £26,511 to be carried forward.

## NORTHWICH ELECTRIC SUPPLY.

The seventh annual report of this Company states that for the past year there were 388 consumers, and the number of lamps in use was equivalent to 18,123 8 c.p., as compared with 351 consumers and 16,678 8 c.p. in 1903. This table includes motors, which now aggregate 227·05 h.p. There is an increase in revenue for current supplied of £190, and from other sources £9, making a total increase of £199. The power load has considerably increased, 39,110 units more than the previous year having been supplied for this purpose, a result fully justifying the policy of charging a low price in order to improve the load factor. The total expenses, however, have been considerably swollen by the cost of opposing rival schemes

## TELEGRAPH CONSTRUCTION AND MAINTENANCE.

The annual meeting of this Company was held on Monday, Sir R. G. W. Herbert presiding. Particulars of the report appeared in our last week's issue.

The Chairman, having reviewed the year's work generally, moved the adoption of the report, which was unanimously agreed to.

In reply to a shareholder, the **Chairman** said he was allowed to tell the shareholders that the Company had made arrangements for the construction of the new Atlantic cable, and that the work would be put in hand before the end of the year.

## CITY OF LONDON ELECTRIC.

The report for 1904 states that the year's capital outlay was £55,827 The total revenue was £256,858. After charging all expenses, adding £21,882 brought forward, transferring £1,220 interest to the debenture stock premium debenture fund, £306 to the staff superannuation fund, £45,000 to reserve, and £500 to reserve for leasehold redemption, and paying the dividends already announced, for which warrants will be posted on 8th inst., there will remain £21,877 to be carried forward. The Company's Extension of Powers Bill and the East London and Lower Thames Electric Power Bill, which has been taken over by the Company's directors, have passed the Standing Orders, and will be introduced into the House of Lords.

Digitized by Google

## CARLISLE TRAMWAYS COMPANY.

The annual meeting of this Company was held at Carlisle on Monday, Mr. T. D. Lingard presiding.

The **Chairman** said that the high prices paid to the Carlisle Corporation for electrical energy had handicapped the Company, and the continuation of a 10 minutes' service in winter instead of a quarter-hour service cost them an expenditure of over £600 to make £200 in extra fares. It was the desire of the Company to oblige the citizens, but it was absolutely impossible to continue the 10 minutes' service while the Corporation were so exacting in their prices. They could have paid a small dividend this year, but the directors thought it better to carry a sum forward.

The report was adopted.

## NOTTING HILL ELECTRIC LIGHTING.

The annual report of the directors made up to Dec. 31 states that the gross revenue for the year was £34,565, showing an increase of £5,120, and the total net profit was £19,890, an increase of £4,872. From the net profit have to be deducted depreciation, renewal, and reserve fund, £2,750; debenture interest, £2,450; and Kensington and Notting Hill joint debenture stock interest and sinking fund, £8,227. The directors recommend the usual dividend of 6 per cent. on both the preference and ordinary shares, and propose that the balance of £3,353 be divided in accordance with the articles of association, one-half, amounting to £1,676, being credited to the founders' shares and the other half to the ordinary and preference shares. This will enable a further 1 per cent. to be paid on both ordinary and preference, with a distribution of £3 per share on the founders' shares. An interim dividend of 3 per cent. was paid to the holders of the ordinary shares on July 1, and the balance of 4 per cent. will be paid forthwith, together with the distribution on the founders' shares. The preference shares having received their full 6 per cent., the 1 per cent. bonus will be added to the interim dividend on these shares, to be paid on July 1 next.

## FALKIRK ELECTRIC CONSTRUCTION.

The first statutory meeting of the shareholders was held at Edinburgh last week. The directors reported that 940 shares of £100 each had been allotted. The total cash received by the Company to date in respect of shares allotted amounted to £17,200. The payments were £15,808, including £4 520 in subscriptions for shares in the Falkirk and District Tramways Company held by the syndicate or its nominees. The preliminary expenses connected with the flotation of the Company were estimated to amount to £1,000, of which sum £800 had already been paid.

The report was adopted.

## BLACKPOOL AND FLEETWOOD TRAMWAYS.

The ordinary half-yearly meeting of this Company was held in Manchester last week, Mr. George Richardson presiding.

The report, of which we gave particulars in our issue of the 10th ult., was adopted.

## NEWCASTLE AND DISTRICT ELECTRIC LIGHTING.

At the annual meeting of this Company, **Mr. J. D. Milburn** stated that 3,259,389 units were supplied last year, as against 2,649 841 for the preceding year. The directors had cemented their connection with the Elswick works, which was proving valuable.

The report was adopted, and a dividend of 8 per cent. per annum for the half-year declared.

## IMPERIAL TRAMWAYS.

The annual general meeting of this Company was held on Saturday at Bristol, Sir George White presiding. The report, of which we gave particulars last week, was adopted.

## ABERDEEN SUBURBAN TRAMWAYS.

The report by the directors for the half-year ending Jan. 31, 1905, recommends that the balance of £1,357 4s., standing at the credit of profit and loss account, should be carried forward, and dealt with at the close of the next half-yearly account. The Company will by that time have had the experience of a full year's working of the line, and may determine, in the light of that experience, how the balance then at credit of profit and loss should be dealt with.

## BRITISH ELECTRIC TRANSFORMER.

The report for the year ending Dec. 31, 1904, to be presented at the meeting on the 6th inst., states that the result of the year's working has been satisfactory. The accounts show that after paying all manufacturing costs and the expenses of administration there remains a net profit of £12,030. 7s. 9d.; which, with the amount brought forward from last year—viz., £1,572. 13s. 4d.—makes a total available balance of £13,603. 1s. 1d., which the Board recommend shall be allocated as follows: depreciation reserve, £1,500; reserve fund, £2 000; preliminary expenses written off, £1,500; payment of preference dividend of 6 per cent. (£537. 12s. paid Aug. 1, 1904), £1,150. 11s. 8d.; payment of a dividend of 7½ per cent. on the ordinary shares, £4,957. 12s.; carry forward a balance of £2,494. 17s. 5d. The two new bays mentioned in last year's report have been completed and fitted with the necessary plant. This extension of the works has been of great value, and has enabled the Company to deal with the increased volume of business. In spite of the general depression in trade the works were fully occupied, and running overtime during the whole year.

## NEW COMPANIES REGISTERED.

**Light Electric Motor Company.**—Capital, £6,500. Object: to acquire and carry on the business of the Light Electric Motor Company, of 164, Howard-street, as manufacturers of electrical specialities and electric power and light contractors.

**Webster Electrical Engineering Company.**—Capital, £10,000. Object: to take over the business of an electrical engineer carried on by C. W. Webster at Laycock's Mill, Thornton-road, Bradford. Registered office: Laycock's Mill, Thornton-road, Bradford.

**Electrical and Hardware Company, Limited (83,661).**—Capital, £1,000. Object: to manufacture and deal in electrical and other lamps, bulbs, bells, batteries, etc.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Salamanca.**—The Municipality requires tenders for public electric lighting. Tenders by March 14.

**Hoylake.**—The Council invite tenders for 250-kw. steam alternator, with piping, etc. Tenders by March 21.

**Bucharest.**—The Telegraph Department require 3,000 kilos of sulphate of copper. Tenders by March 7.

**Salford.**—Tenders are required by the Corporation for the alteration of storage batteries. Tenders by March 4.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**Leeds.**—The Corporation require tenders for the complete equipment of two sub-stations. Tenders by March 14.

**Verin (Spain).**—The Municipal Authorities require tenders for installation of public electric lighting. Tenders by March 9.

**Barcelona.**—The Municipality require tenders for arc lighting of La barriada de San Gervasio de Cassolas. Tenders by March 15.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station.

**Bucharest.**—The Post and Telegraph Department require tenders for 14 000 large, 8,000 medium, and 3,000 small insulators. Tenders by March 16.

**Fulham.**—The Borough Council invite tenders for the supply of electrical stores for year ending March 31, 1906. Tenders by 4 p.m. on March 15.

**Zurich.**—The Swiss Electricity Works (Schweizer Electricitätswerke) require tenders for 294,600 incandescent electric lamps. Tenders by March 15.

**Madrid.**—The Post and Telegraph Department, Carretas No. 10, require tenders for 32,000 zinc cylinders for Collaud batteries. Tenders by March 15.

**Plymouth.**—The Corporation invite tenders for the supply of electricity meters, transformers, and cables (paper insulated). Tenders by March 18. See advertisement.

**Bucharest.**—The Roumanian Government Railways require tenders for telegraph poles as follows: 2,000 7m. long, 2,000 8m. ditto, and 500 9m. ditto. Tenders by March 10.

**Johannesburg.**—The Corporation require tenders for 30 direct-current arc lamps with lanterns. Tenders by March 15 to Messrs. Mordey and Dawbarn, 82, Victoria-street, S.W.

**Stoke Newington.**—The Council invite tenders for the supply, delivery, and erection of sub-station plant and mains. Tenders by 4 p.m. on March 8. See advertisement in previous issue.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Shoreditch.**—The Council invite tenders for their yearly contracts in the electricity works and other departments. Tenders by March 14. Full particulars in our advertisement columns.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Madrid.**—The Post and Telegraph Department, Calle de Carretas 10, require tenders for telephone and telegraph apparatus, estimated at 35,337·50 pesetas. Tenders by March 10. This includes 50 Morse receivers.

**Lowestoft.**—The Corporation invite tenders for one water-tube boiler with superheater, brickwork settings, and accessories, together with the necessary pipework. Tenders by March 9. See advertisement in previous issue.

**Manchester.**—The Tramways Committee of the Corporation invite tenders for the supply of cement, chippings and broken stone, veterinary services, and general stores. Tenders by March 6. For full particulars see advertisement.

**Dax (France).**—Tenders are required for a concession to erect and work electric lighting of the town for 35 years. Particulars may be obtained from the Secretary to the Municipality of Dax, Province of Landes, France. Tenders by March 6.

**Swindon.**—The Corporation invite tenders for annual supply of incandescent and Nernst lamps; cables; fuse boxes, service boxes, and

Digitized by Google

feeder pillars; lubricating oils and grease; and direct-current meters. Tenders by March 21. See advertisement.

**Great Western Railway.**—The directors invite tenders for the supply, delivery, and erection of plant in connection with their electricity generating station at Park Royal and proposed sub-stations and distributing centres at various places. Tenders by March 13.

**Wimbledon.**—The Urban District Council invite tenders for the supply of (3) engine-room stores, (4) cables, (5) joint-boxes and jointing materials, (6) transformers, (7) meters, (8) oils, (9) incandescent electric lamps, carbons, and accessories, (10) iron castings. Tenders by March 4.

**Madrid.**—Der Compania Electrica Madrilena de Traccion propose to extend their electric tramways from the Barquillo-street to Olivide-place. The concession for the works will be dealt with by the Public Works Department, Madrid, April 2. Tenderers for same must deposit a guarantee of £96.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Stockport.**—The Corporation invite tenders for the team and manual labour and the supply of sand, drain boxes, and drains (only) in laying the permanent way of about 3½ miles of double line of tramway, including laying of special work in junctions and crossovers. Tenders by noon on 13th inst.

**Newport (Mon.).**—The Electricity and Tramways Committee invite tenders for 300-kw. continuous-current high-speed tramway generator (engines of enclosed type), 200-kw. continuous-current high-speed steam balancer (engines of enclosed type), boiler, switchboard, stores, etc. Tenders by March 6. See advertisement.

**Edinburgh.**—The Corporation invite tenders for the annual supply of arc lamp carbons, cast-iron pavement and road boxes, electricity meters, house service fuse-boxes, earthenware troughing for laying electricity cables on the solid system, bitumen, and arc lamp globes. Tenders by March 13. See advertisement.

**Gloucester.**—The Electricity Supply Committee invite tenders for three Lancashire boilers and accessories, one 600-kw. generating set and accessories, electrically-driven surface-condensing plant to deal with 30,000lb. of steam per hour, steam, exhaust, feed, drain, condensing water, and sundry pipes, valves, etc., and an electrically-driven boiler feed pump, the whole bound up in one specification. Tenders by March 16. See advertisement.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**South Shields.**—The Electricity Supply Department invite tenders for the supply, delivery, and erection of the following plant: (Contract No. 67) one multitubular marine-type boiler, with chimney and mountings; (68) two medium-speed open-type vertical engines for two 550-kw. direct-current traction generators; (69) two 550-kw. direct-current traction generators; (70) traction switchboard; tramways department—(Contract No. 4) electric tramcars, complete with "Brill" trucks, for the Corporation. Copies of specifications, conditions, form of tender, also form of contract, can now be obtained from Mr. J. H. Cawthra, M.I.E.E., borough electrical engineer, South Shields, on payment of £2. 2s. for each contract, which sum will be returned on receipt of a bona fide tender for each contract. Tenders to Mr. J. Moore Hayton, town clerk, Court-buildings, South Shields, by noon on March 13.

**Johannesburg.**—The Municipal Council are prepared to receive tenders for 100 electric tramcars, two electric water-cars, one five-ton travelling crane, one electric car traverser, and various workshop tools, including erection at Johannesburg, to Specification No. 10 of their consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W. Copies of the specification may be seen on and after Jan. 7 at the Council Offices, Johannesburg, and at the Consulting Engineers' Offices in London, and may be obtained on payment of five guineas, which will be returned on receipt of a bona fide tender. Duplicate copies of the specification may be bought for 10s. each (not returnable). Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W., and must be received by them not later than March 6. The Council will not be responsible for any expenses incurred in tendering.

## RESULTS OF TENDERS.

**Stoke-upon-Trent.**—The Town Council have accepted the tender of Crompton and Co. for a 22-h.p. motor, at £74. 17s., subject to 2½ per cent. discount.

**Derby.**—The Electric Lighting Committee have accepted the tender of the Sunbeam Lamp Company for the supply of incandescent lamps during the ensuing year.

**Southend.**—The Town Council have accepted the tender of W. E. and H. B. Davey, at £1,558. 13s. 2d., for the extension of the boiler-house at the electricity works.

**Leith.**—The tender of Messrs. M. P. Galloway, Limited, has been accepted by the Tramways Reconstruction Sub-Committee for the supply of centre poles and accessories to be used in the electrical reconstruction of the tramway system, at £4,471.

**Brighton.**—The Lighting Committee of the Town Council recommend that the tender of Siemens Bros., at £2,350, be accepted for the supplying and laying of low-tension cables from Fishersgate-terrace, Southwick, to the point of supply to Aldrington.

**Salford.**—The Electricity Committee have received tenders for the supply of cables from the British Insulated and Helsby Cables, Callender Company, Dennis and Co., Electrical Company, W. T. Glover and Co., W. T. Garnett, and Henley's Telegraph Works Company.

**Grimsby.**—The Sub-Committee have recommended that a water-purifier be purchased from Messrs. Lessen and Hjort for the sum of £315, that motors be supplied by Crompton and Co., and that the tender of the Keighley Electrical Engineering Company for motor starters be accepted.

**Rochdale.**—The Corporation have accepted the tender of the British Thomson-Houston Company, Limited, Rugby and London, for the supply, delivery, and erection at the electricity works of high-tension three-phase switchgear and extensions to the low tension continuous-current switchboards.

**Erith (Kent).**—The Urban District Council have accepted the following tenders: (Contract 5) overhead line equipment, etc.—Brush Electrical Engineering Company, Loughborough, £4,217; (6) underground feeder cables, etc.—Callender's Cable, etc., Company, Belvedere, Kent, £2,590. 4s.; (7) rotary converters, etc.—British Westinghouse Electric, etc., Company, Norfolk-street, Strand, W.C., £1,545 5s.; (8) main high and low switchboards, etc., Kelvin and J. White, Limited, Glasgow, £1,047. 10s.

**Leith.**—The Electric Lighting Committee of the Town Council have considered tenders for a boiler, a dynamo, and a switchboard, required in connection with the extension that is being made at the electrical station to provide additional power for the working of the new tramway cars. The contract for the boiler was placed with Babcock and Wilcox, at £2,287. For the dynamo there were 83 tenders, and the committee made a selection, which, however, is subject to an arrangement. The 26 tenders for the supplying of a switchboard are before a sub-committee with powers.

# BUSINESS NOTES.

## TRACTION.

**Leeds.**—The Corporation have adopted the alteration in fares mentioned in our last issue.

**Geneva Tramways Co.**—The receipts for January amounted to £76,016, against £444 last year.

**Derby.**—The section from the corn market to the Market-place has been inspected by the Board of Trade.

**Llanelly.**—The Urban District Council are depositing a formal petition against the Electric Traction Bill.

**The Machynlleth Light Railway.**—The Board of Trade have confirmed this order subject to a few conditions.

**Manchester.**—A sub-committee has been appointed to visit the route between City-road and Moss Side, with a view to constructing a line.

**Linlithgow.**—It is reported that the District Committee have refused their consent to the proposed electric tramway between Edinburgh and Queensferry.

**Yardley.**—It is stated that the City of Birmingham Tramways Company have approached the District Council with a view to substituting a motor 'bus service for the prospective electric trams to Shirley.

**West Cumberland.**—The Bill to further extend the period for the completion of the tramway has been found to comply with the Standing Orders of Parliament, and has been sent for second reading in the House of Lords.

**Kirkcaldy.**—At the meeting of the Town Council Mr. Francis, burgh surveyor, recommended an extension of the service, including the doubling of certain lines. The Council have instructed Mr. Francis to report upon the cost.

**Glasgow.**—The extensions of the Glasgow system from Johnstone to Kilbarchan and of the Paisley Company's system to Barrhead are likely to proceed it appears, the Renfrew Council having now waived their stipulation as to double lines.

**Bradford Road.**—The British Electric Traction Company, who asked for an extension of their license to use steam on the Bradford Road lines for another 12 months, have been informed by the Board of Trade that only six months can be allowed.

**Gisburn Light Railway.**—The Light Railway Commissioners announce that the promoters of the Barnoldswick and Gisburn light railway order have abandoned their application, the reason being inability to make arrangements with either of the existing railway companies.

**South Lancs. Tramways Co.**—The company decline to issue season tickets on their system. The greater proportion of tramways revenue, it is pointed out, is derived from the working classes, and, as these cannot prepay their fares, the adoption of contracts would create a favoured class of passengers.

**Edinburgh.**—Matters of general policy in connection with the extension of the tramway system in and around the city were under discussion by a sub-committee, with the result that the town clerk has been instructed to prepare a full report on the situation, enlisting the services of Prof. Kennedy, if necessary.

**Yarmouth.**—The arbitrator, Mr. Graham Harris, has fixed the amount which the Corporation is to pay the Gorleston Tramway Company for their undertaking at £13,400, together with the cost of the fodder in stock at the depôt. The Corporation are to pay the costs. The Corporation were asked £19,000 for the undertaking.

Digitized by Google

**Aston.**—An accident occurred on the newly-opened Small Heath route on Saturday night, when two cars were approaching each other from opposite directions. They were about six yards apart, when a horse and four-wheeled van went between, and became wedged. The van was driven by a man in the employ of the Corporation health department, who was arrested.

**Hastings.**—The company's Bill has been referred to the Standing Orders Committee in respect of non-compliance in regard to the Bexhill section. The suggestion for a conference between the company and the Hastings Corporation has been revived. Good progress is being made with the work of construction. A formal meeting of the company was held last week, when it was stated that everything was proceeding satisfactorily.

**Coventry.**—On the Standing Orders Committee of the House of Commons considering the report of the Examiners of Private Bills, it appeared that the Standing Order requiring the consent of the local road authority had not been complied with in the case of the Coventry Electric Tramways Bill. There was no appearance entered by the parliamentary agents, and it was intimated that the Bill will not be proceeded with.

**Greenock.**—The Greenock and Port Glasgow Tramways Company has appealed to the High Court, London, against the decision of the Board of Trade awarding the sum of £602. 19s. 9d. as the proportion of profits due to the Corporation, and also ruling that the company is to account for two sums of £75 set aside for maintenance and £1,500 placed to depreciation. The plea of the company is that the Board of Trade acted *ultra vires*.

**Italy.**—The *Gazzetta Ufficiale* publishes decrees authorising the Leghorn Tramways Company to construct and work an electric tramway in that city; authorising the Carthagena Tramways Company to substitute electric for animal traction on the lines between Carthagena and San Antonio Abad, Dolores, Barris, Peral, and Santa Lucia; and authorising the Roman Tramways and Omnibus Company to substitute electric for animal traction on the tramway between the Piazza del Popolo and Ponte Milvio.

**London County Council.**—The receipts for the week ended Feb. 18 amounted to £12,878, against £9 653 for the corresponding week of last year, and from April 1 to £588 357, against £456,442. The invitation from the Shoreditch Borough Council to support a request that the County Council should experiment with motorcars for its northern system has met with a lukewarm reception from the Stoke Newington Borough Council. The second reading of the County Council's Tramway Bill has been postponed until the 7th inst.

**North Metropolitan Tramway Co.**—At the meeting of this Company Mr. G. Richardson, who presided, stated that there was no doubt the time was coming when locomotion in the streets would be altered, perhaps in favour of motor 'buses as against horse 'buses. So far as the company was concerned, the point that would affect them was when they would be able to get a suitable motorcar which would run upon the rails. The directors were carefully watching developments, so that at the proper time they would run these motorcars instead of those propelled by electricity.

**Rochdale.**—At a meeting of the Tramways Committee it was decided to commence the reconstruction of the line along Bolton-road to the borough boundary at Heywood Cemetery on, or if possible before, March 13, and as soon as the work there is done the men will be transferred to the Littleborough section. A deputation of the Whitworth District Council waited on the committee, and asked them to take into favourable consideration the question of extending the lines and running into the Whitworth district. The committee decided to go fully into the subject at a future meeting.

**South Australian Tramways.**—In pursuance of the article on this subject in our last issue, we note that the private tramway companies have retained the services of Sir Josiah Symon as their legal adviser during the negotiations, and have appointed Mr. H. F. Rymill as arbitrator on their part. The Government have not yet announced their choice. When both arbitrators are appointed, application will be made to the Supreme Court for directions as to procedure. We are informed that a tracing of the lines in question may be inspected at the offices of the Agent-General for South Australia, 1, Crosby-square, E.C.

**West Bromwich.**—The following resolution is to be moved at the next meeting of the Council: "That the General Purposes Committee be empowered to take proceedings against the tramways company to enforce the terms of their agreements and leases with the Corporation." What the Corporation complain about is that the tramway company are running a 10 minutes' instead of a seven minutes' service of cars between Carter's Green and Great Bridge, and also Carter's Green and Wednesbury; and, further, that they have failed to carry out their agreement in not providing proper shelters for the convenience of passengers.

**Cardiff.**—At a meeting of the Tramways Committee last week the estimate for the year ending March 31, 1906, was submitted. From this it appeared that the estimated expenditure was £110,643. 3s., as compared with £112,385. 14s. 2d. for the year ending March, 1905, while the revenue was estimated to be £115,709, as compared with £118,366 for the year about to end. There was, therefore, a decrease both in the revenue and the expenditure, but the revenue showed an estimated balance over expenditure of £5 065. 17s. The figures for the year just ending were, however, only estimates. The estimate was adopted.

**Edinburgh.**—The Corporation have decided to apply for sanction to an electric tramway from Tolleross along Gilmore-place to the Edinburgh Hydropathic, thence back to the city by Slateford and Fountainbridge; a line from the top of Broughton-street to the burgh boundary at Pilrig-street, and from Canonmills to join the line at Bellevue. The Council declined to grant permission to a private syndicate to construct an electric tramway from Fountainbridge to Slateford. They approved of an application by the National Electric Construction Company for a new order amending the Portobello and Musselburgh Tramways Orders.

**Falkirk.**—There has been some little friction between the tramway company and the Corporation. The company propose to take energy in future from the Scottish Central Power Company, whose right to supply same is disputed by the Corporation, who now offer to provide power on the following terms: 2d. per unit for the first 100 000 units, and 1½d. thereafter, with a minimum consumption of 100,000 units per annum, the supply to be given by meter at the generating station, and to be direct current at from 500 to 550 volts; the maximum demand not to exceed 150 kw., and the hours during which supply is to be given to be within 5 a.m. and 11 p.m. on weekdays.

**The Underground.**—A successful experiment was made on the Metropolitan Railway on Monday night after the ordinary traffic had ceased. An electrically-propelled train was run from Neasden to Baker-street, where it crossed to the company's portion of the Inner Circle line. From Baker-street the train proceeded to Notting Hill-gate and thence to Aldgate, after which it returned to Baker-street. An extraordinary general meeting of the Underground Electric Railways Company of London, Limited, was convened for yesterday for the purpose of passing resolutions authorising the directors at their discretion to raise or borrow or secure the payment of any sum or sums of money for the purposes of the company, not exceeding £4,000,000, in addition to the amounts which they are at present authorised to borrow, etc.

**Aberdeen.**—At a meeting of the Tramways Committee a discussion ensued as to the issuing of celluloid tokens and season tickets. The consensus of opinion was to the effect that celluloid tokens should only be issued at their face value—namely, 12 for 1s.—as in all other corporations in the south it was found that this was the system on which they were given out, no reduction being given even for the purchase of a number of those tokens. It was also considered that season tickets on the various routes were in a number of cases issued at too low rates, but in view of the close of the financial year in May, before which any rearrangement of fares over the whole system must take place, it was resolved to call a special meeting next month to consider the three questions of the issuing of celluloid tokens, season tickets, and the extension of ½d. tickets, or, alternatively, a universal 1d. fare.

**Wellingborough.**—The Wellingborough and District Tramroads and Electricity Supply Bill came before Mr. Campion, examiner of Bills for Standing Orders, at Westminster, last week, for proof of compliance with the Standing Orders of Parliament. There was no opposition at this stage, but with regard to the withholding by Northamptonshire County Council of their consent to the new lines promoters contended, upon certain technical grounds which they advanced, that the consent of the County Council was unnecessary. The examiner, however, decided against the promoters, and intimated that he would report non-compliance with the Standing Orders of the Committee of the House of Commons. Councillor Joseph Wilson has given notice of a motion, "That the Tramways Committee be requested to consider and report upon the desirability of introducing self-propelled motorcars or omnibuses to work in conjunction with, or apart from, the present system of electric cars."

**Municipal Tramways.**—At a further conference held of representatives of municipal tramways, held at the Westminster Palace Hotel, the clauses in Railway Bills as to the running of omnibuses were considered, and it was decided to obtain a modification of those clauses as far as possible, so that the omnibuses should be limited to running to and from the stations of the companies. The question of the erection of guard wires over the trolley lines in places where telegraph and telephone wires crossed the trolley lines was also considered. As the law stands at present, if the tramway promoters were first in the field, and the Postmaster-General subsequently desired a telegraph wire to be erected over a trolley line, the tramway promoters were called upon by the Board of Trade to erect guard wires at their own expense. This the promoters considered to be an unfair and inequitable arrangement, and it was determined to request the Board of Trade to receive a deputation on the subject, and also upon the question of certain regulations recently issued by the Board of Trade on the subject of the construction of cars and other matters connected with tramway equipment.

**Leicester.**—At a special meeting of the Town Council on Tuesday, Councillor Flint, chairman of the Tramways Committee, presented the report for the year. The total receipts, including rents and bank interest, were £79 900, and the working expenses £47,993, leaving a gross profit of £31,907. They had paid in interest and sinking fund £18,849, leaving a net balance on the year of £13,088. By way of comparison, Councillor Flint stated that the gross receipts in 1903 were £47 599, signifying an increase of £31,126 for the past year. The working expenses in 1904 amounted to £47,993, and in 1903 to £38 850, an increase of £9,143. The passengers carried in 1904 numbered 18,394,183, against 10 813 430, an increase of 7,580,753. The car miles run were 1,850,479, against 960,934. It will be remembered that mixed traction has been in use this year, owing to reconstruction for electric working, and Councillor Flint gave some interesting figures in relation to the two systems. With horse traction the receipts averaged per car mile 10 41d., while for the electric cars the average was 9 70d., this being accounted for by the longer distance which the electric cars carried passengers, and by the lateness of the season when they commenced running. The working expenses were all in favour of the electric car. The horse traffic cost 8·85, while the electric traffic cost only 4 82, a difference in favour of the electric traffic of 4·03. The committee proposed to devote the balance of £13,000 to a reserve fund for maintenance and repairs instead of creating a depreciation fund. In conclusion, Councillor Flint alluded in appreciative terms to the efforts of

Digitized by Google

the staff, particularly Messrs. Mawbey, Lucas, and Smith. An amendment in regard to the appropriation of the balance was submitted by Councillor Kemp, who thought it ought to be devoted to reducing the capital account. Eventually the report was adopted unanimously.

**South Shields.**—At a meeting of the Town Council on Wednesday a deputation was received from the South Shields Property Owners' and Ratepayers' Association on the question of motor omnibuses *v.* electric trams. The leader of the deputation said that it represented not only the Property Owners' and Ratepayers' Association, but also a representative body of ratepayers, and they asked the Council, before committing themselves to the laying of tramlines, to seriously consider the desirability of adopting some other system, such as motor 'buses, which would be more up-to-date, more appropriate, more adaptable, and cheaper than electric trams. The memorial had been signed by 730 ratepayers of the borough, but this did not adequately represent the feeling of the town on this question. The petitioners, therefore, asked that an exhaustive enquiry founded on expert and unbiassed evidence, should be held, so that South Shields might have the best and most up-to-date system of locomotion. Alderman Readhead, in supporting the memorial, remarked that three reasons were given for the adoption of motorcars—viz.: (1) Less cost in the purchase and working of motor 'buses; no cost of street widenings or laying of lines; and overhead gear not required. (2) Freedom of motion, there being no necessity for motor 'buses to keep to any particular route or routes; their ability to run outside the borough; less interference with traffic; and less danger to the public. (3) That other electric tram companies are now adopting motor 'buses in substitution for such trams, and that if the Council adopt electric trams some private company may compete against them with motor 'buses. He suggested that the Council should acquire three motor 'buses at an estimated cost of £3,000, which could be run over the Westoe-lane and Stanhope-road routes, and they would then be able to judge whether or not it would be advisable to adopt them generally instead of the trams. Councillor J. Grant, speaking on the Tramway Committee's report, referred to the discussion in committee on the question of motor omnibuses, remarking that the reason the committee rejected the motion in favour of an enquiry was that at that time they had no data to go upon, and all the statements then made were purely hypothetical. Everyone knew what an electric car could do, but no one could tell them the extent of life of these motor 'buses. He pointed out, in contradiction to statements which had gone abroad, that the total costs of the tramway system would not exceed £129 000. An animated discussion ensued, Alderman Rennoldson remarking that the Council had no power to run motorcars. Councillor Barlow supported a resolution for an exhaustive enquiry into the matter, on the ground that the motorcar was making great strides, and eventually this was agreed to, the report to be presented at a special meeting in two or three weeks' time.

**Dalkeith and Bonnyrigg.**—At a conference between representatives of the Dalkeith and Bonnyrigg Town Councils and representatives of the Edinburgh Suburban Electric Tramway Syndicate in regard to the proposed electric tramway from Edinburgh to Dalkeith and Bonnyrigg, Provost Chisholm submitted a memorandum of suggested conditions and provisions, which had been approved by the Dalkeith Town Council the previous day, and of which the following are the chief: The company to be bound within one year from the date of the passing of the provisional order to substantially commence the work of laying down the tramways, and within two years from said date to complete the tramways and open them for the public conveyance of passengers. The tramways within the burgh to be laid as a double line, except in such portions as may be adjusted with the Council, and the precise position of the lines also to be adjusted with the Council or their surveyor. The size, position, design, and construction of all posts, standards, wires, supports, and other apparatus must be first approved of by Town Council, but such approval not to be unreasonably withheld. The Council or their lighting contractors to be entitled to free use thereof for electric or gas lighting. The posts, standards, and supports to be painted and kept painted to the satisfaction of Council. All cars to be of most modern and approved design, which is to be approved of by Council. The cars to be lighted by electricity and to be provided with lightning arresters. Fares not to exceed 1d. per mile. Through fare Nether Liberton to Dalkeith not to exceed 4d., and Dalkeith to Bonnyrigg 1½d. Fares for workmen's cars not to exceed half these rates. The Council to have option on six months' notice to acquire undertaking in burgh (and rest of tramways, also subject to rights of local authorities outside burgh) on the following terms: (1) at expiry of 14 years from commencement of order at valuation to be fixed by arbitration upon the basis of cost of construction (less depreciation), and (immediately preceding) four years' net profits in name of goodwill; (2) after expiry of 21 years as above, with two (immediately preceding) years' net profits for goodwill; (3) after 28 years on same terms, with profits for one year (preceding) for goodwill; (4) at expiry of 42 years on same terms without goodwill. Before selling undertaking to other than the Council, six months' notice and offer to be made to this Council on same terms. Goods, minerals, and animals only to be carried by company with consent and on terms and conditions approved of by Town Council. Company to pay Council at rate of £50 per mile as rent for lines within burgh, so soon as company pays its shareholders 5 per cent., with £50 additional per mile for every 1 per cent. paid to shareholders over 5 per cent. Company to repair and make good all streets, roadways, and footpaths opened or broken by them at any time, and Council be at liberty, after notice, to do so in event of company's default and at their expense. These conditions were approved of generally, with the exception of the proposed terms of acquisition by the Council and the proposed rent to be paid by the company after it earns a dividend. The syndicate could not see their way to agree to these proposals, and the Council representatives agreed to consider as to the modification thereof. Provost Gilchrist stated than the Bonnyrig Committee concurred in the provisions suggested by Provost Chisholm on the understanding that the Bonnyrigg section of the undertaking should be proceeded with concurrently with Dalkeith.

## LIGHTING AND GENERAL.

**Partnership.**—Particulars of a partnership open appear in another column.

**Thirsk.**—On Wednesday telephonic communication was opened at Thirsk to all parts.

**Cairo.**—The electric lighting of the town is to be greatly extended. The French gas company has the monopoly.

**Lighthouses.**—During last year to March, £3,847 was spent on establishing electric communication with lighthouses and light-vessels.

**Cardiff.**—An enquiry has been held into an application of the Corporation for sanction to borrow £87,868 for purposes of electric lighting.

**Chester.**—The discussion on the public electric lighting has been adjourned until a further report has been received from the electrical engineer.

**Southend.**—The electrical engineer has submitted a report urging the need for the installation of the additional plant in time for the summer load.

**Bournemouth and Poole Electric Supply Co.**—The directors recommend a dividend on the ordinary shares of 7 per cent. per annum for the year 1904.

**Swindon.**—An enquiry has been held into an application of the Corporation for sanction to borrow £22,000 for the extension of the borough electricity works.

**South Shields.**—The following reductions in the charges for electric energy have been made: after the first hour's consumption from 2d. to 1½d. per unit, and the flat rate from 5d. to 4d.

**East Barnet.**—The Council have decided that negotiations with the North Metropolitan Electric Supply Company for the supply of electricity to East Barnet should not be proceeded with.

**Torquay.**—A post-card poll of the ratepayers concerning the scheme is about to be taken in regard to the Corporation's proposal to construct a new electric light and power station at a cost of £42,000.

**Penrith.**—The Local Government Board has refused to accede to the application of the Urban District Council for sanction to borrow £6,850 for the purpose of laying down an electric lighting plant.

**Colchester.**—In reference to the application for sanction to the borrowing of £16,500 for purposes of electric lighting, the Local Government Board have sanctioned £12,920 without, it appears, specifying the items excluded.

**Electric Supply in the Metropolis.**—The London County Council on Tuesday adopted the report of the Parliamentary Committee, fully dealt with in our last issue, and decided to leave open the date of the proposed conference.

**Metropolitan Electric Supply Co.**—The directors recommend the payment of a final dividend for 1904 of 11s. per share on the ordinary stock, making a total distribution for the year of £1 per share, or 10 per cent., carrying forward £9,000.

**Fulham.**—The charges for lighting decided upon by the Borough Council on Wednesday are as follows: a flat rate of 3½d. per unit, with a discount of 2½ per cent. on all bills over £2 per quarter and 5 per cent. on all bills over £5 per quarter if paid within 14 days.

**Paisley.**—The electric light installation at the refuse destructor works was formally inaugurated last week. Bailie Fisher, convener of the Electric Lighting Committee, started the engine, and Bailie Glover, convener of the cleansing department, switched on the current.

**Hackney.**—The borough engineer and surveyor, Mr. Norman Scorgie, in his report for the year ended March, 1904, says that during that year 40 seven-ampere "open" type arc lamps have been placed at a distance of about 100 yards apart in three roads in lieu of 91 existing gas lamps.

**Kent Electric Power Co.**—This company, which is incorporated by special Act of Parliament, and has for its operations the county of Kent, has completed the purchase of the undertaking of the Chatham, Rochester, and District Electric Lighting Company, Limited, as from Jan. 1 last.

**Removal.**—Messrs. Oetzmann and Co., of 62 to 79, Hampstead-road, W., announce that they have purchased the entire stock of Messrs. Norman and Stacey, Limited, of 252 to 256, Tottenham Court-road, and are now removing it to their own showrooms and galleries in Hampstead-road.

**Ormskirk.**—The Urban District Council have now adopted an electric lighting scheme, which includes the provision of a refuse destructor, and is estimated to cost £20,000. The Council have entered into a provisional agreement with the Electric Construction Company to carry out the works.

**Grimsby.**—A temporary draughtsman is to be engaged to assist in preparing a scheme for the enlargement of the electricity station and the extension of the plant. During the last year the increase of lamps was about 16,000, the average increase since the department was established having been 10,841 per annum.

**Arbroath.**—Matters with regard to the proposed electric lighting are apparently not getting any forwarder. The Council are corresponding with the Empire Electric Lighting Company with regard to a provisional agreement entered into in October last. In the meantime the Board of Trade have revoked the order.

**Bath.**—The Council have adopted a report in which Mr. Teague showed the necessity of extending the continuous-current generating

Digitized by Google

plant required to prepare for next winter's load, and although this extension will cost £1,321 more than another generator, Mr. Teagne considers that there will be an annual saving in the cost of generating of £300 a year.

**Annual Dinner.**—The seventh annual dinner of the Central Technical College O'd Students' Association was held at the Trocadero Restaurant, Piccadilly, on Wednesday, Feb. 22. About 60 Old Centralians were present, the guests including Sir William Crookes, F.R.S., and Dr. Hartog, the academic registrar of London University. Prof. W. E. Ayrton occupied the chair.

**London Telephone Exchanges.**—Lord Stanley on Wednesday, in reply to a question of Sir T. Dewar, said 11 Post Office telephone exchanges were open in London on Dec. 31 last, and the number of subscribers in connection with them was 22,181. The amount of annual rental payable for the use of these instruments, together with messengers' fees, during 1904 was £156,485.

**Hull.**—We understand that the large contract with Messrs. Earle's Shipbuilding and Engineering Company for the supply of electricity to the company, which will expire in May, is to be renewed for a further 12 months. The town clerk's report in respect to the hiring of electric motors, and a suggestion that motors be purchased out of revenue, has been referred to a sub-committee for report.

**Swansea.**—The Corporation, under the terms of the license held from the Postmaster-General, considers itself entitled to demand from the National Telephone Company intercommunication between the subscribers to the two rival systems. Various reasons have been put forward by the company for resisting the demand, and we understand legal action is being taken by the Corporation to enforce it.

**Glasgow.**—The following information has reached us: The National Telephone Company has now 20,000 telephones on rental working in the Glasgow district. Their net increase for last week amounted to the enormous total of 215 telephones, which is a record. The company has during the past month opened four new exchanges in this district, thus bringing a number of outlying villages into touch with the city.

**Gloucester.**—The Council have agreed to borrow £24,673 for the purpose of carrying out electric lighting extensions. At the last meeting of the City Council Alderman Fielding expressed satisfaction that the report of Mr. R. A. Chattock on the proposed extensions of the electricity plant confirmed the report of their own engineer, Mr. Bache, both with regard to the extension and the probable profit on the undertaking.

**Agencies.**—Messrs. Hellesens Enke and V. Ludvigsen, Blaagaardsgade 14 and 17, Copenhagen N., Denmark, have appointed Messrs. Fuller, MacLeod, and Co., Limited, of Norfolk House, Laurence Pountney-hill, Cannon-street, their sole agents for Great Britain for the Hellesen dry cells. Messrs. Monté Calow and Co., 6, Ludgate-broadway, E.C., have resigned their agency for Messrs. Lionel Robinson and Co.'s specialities.

**Croydon.**—Tenders are to be invited for coal supplies for the ensuing year, and also for supply of cables. The following particulars are available: current sold this year—private lighting, 136,577 units (corresponding period last year, 105,343 units); public lighting, 54,243 (47,153); traction, 89 563 (81,161). The extension of mains to supply current to houses in Craignish-avenue is to be carried out as recommended by the borough electrical engineer.

**Elland.**—The Electricity Committee, in their statement of the first year's working of the combined refuse destructor and electricity works, say that the total receipts have amounted to £655, and the working expenses to £442, leaving a gross profit of £213. This is, however, more than absorbed by the interest and repayment of principal on the borrowed capital of £16,000 which amounts to £833, leaving a net deficiency on the year of £670.

**South Africa.**—The King William's Town Corporation have just taken over the local electric lighting undertaking, and will soon be giving out new orders; while Potchefstroom is greatly concerned about its electric lighting arrangements. They had agreed to purchase the local company's business for £6 000, but Mr. Stevens, the Government electrical engineer, reports that the plant is inadequate to the needs of the town.—*South African Traders' and Export Gazette.*

**Manchester.**—The chief engineer in a recent report dwelt on the need for further capital expenditure. This does not concern extensions at the chief generating stations; the money is required chiefly for extensions of mains and for generators, etc., at the sub stations. For instance, there is no room at Dickinson-street for more boilers, and it has been decided to introduce three generators of 500 kw. capacity each, and drive them from high-tension mains from Stuart-street.

**Wimbledon.**—The Council have agreed to charge a flat rate of 2½d. per unit for all units consumed for street-lighting as from April 1 next. On and after that date the incandescent street lamps will be kept lighted from dusk to dawn, and each alternate arc lamp switched off at midnight. The electrical engineer's plans and estimate for the additional plant and extensions required at the electricity works have been approved, and application will be made for sanction to borrow £13,218.

**Stoke-on-Trent.**—A committee of the Guardians have considered a proposal made by the electrical engineer at the workhouse that they should dispose of the storage battery and instal a dynamo to take the night load. A tender offering £75 for the battery and other apparatus, of which it was proposed to dispose, and offering to supply the dynamo which it was proposed to instal at £100, has been received. The opinion of an independent electrical engineer is to be obtained on the matter.

**Dartmouth.**—An electrical exhibition was opened at the Dartmouth Subscription Rooms on Wednesday last week by Mrs. Gouldsmith, who was introduced by Mr. H. Brent Grotrian, a director of the Urban Electric Supply Company. A vote of thanks to Mrs. Gouldsmith was moved by another of the directors of the company, Mr. J. C. Wigham, who explained some of the many uses to which electricity can be put. He particularly referred to the hospital ward. The vote was seconded by Lord Aylesford.

**Middlesbrough.**—The electrical engineer (Mr. Taylor) in his last report states that 116,000 units have been generated during February, against 70,000 for the corresponding month last year. The estimated revenue for the past month was £1,477, against £1,020, an increase of £457, although the selling price had been reduced by 10 per cent. The total cost had been £476, against £338. The estimated profit for the month was £1,001, exclusive of interest and redemption. The lamps connected to date numbered 71,400, and there were applications in hand for a further 4,764 lamps.

**Exports to the British Colonies.**—We are informed that, owing to the growth of their export business, the Union Electric Company, Limited, 151, Queen Victoria-street, E.C., are sending out one of their most experienced officials, Mr. C. O. Barwell, for a trip through the British Colonies—in fact, round the world. The main objects of this extensive trip are to ascertain the condition of the Colonial markets, appoint agents for the purpose of furthering the company's and general interests in the British Colonies by personal activity. We understand that Mr. Barwell is open to represent one or two other leading electrical firms whose interests do not conflict with the Union Company's.

**Eastbourne.**—The following figures are available for the year ended March 31, 1904: Number of 8 c.p. lamps connected at end of year (arcs, incandescents, and motors, equivalent in 8 c.p.), 64.898, previous year 56,227; units sold, private supply 733,322 (628,685), public lighting 163,871 (40,446)—total, 897,193 (669,132); units sold per 8-c.p. lamp (connections during the year averaged), 14·8 (13 0); maximum load on feeders in kilowatts, 743 (629); load factor, 13·75 per cent. (12·14 per cent.); capacity of dynamos at end of year, kilowatts, 1,200 (1,200); average price obtained, private supply 5·95d. (6·18d.), public lighting 3·02d. (4 08d.). Prices charged: private lighting 6½d. per unit; power and heat, 3d. per unit; hotel and theatre lighting, maximum demand system, with initial charge of 7½d. per unit for daily average of one hour and 4d. per unit after; public lighting, arc lamps, £25 per lamp per annum.

**Newcastle.**—A report as to the comparative statement of the annual cost of gas and electric lamps was issued to members of the City Lighting Committee of the Corporation on Wednesday by the lamp inspector (Mr. George Lamb). In this report the inspector, among other suggestions, says: "The thoroughfares of Walker are lighted by 235 16-c.p., 95 25-c.p., five 32-c.p., and three 50 c.p. incandescent electric lamps, there are also eight enclosed arc lamps. In this report it is proposed to deal only with the 25-c.p., 32-c.p., and 50-c.p. lamps, the annual cost of which is £328. 15s. 6d., and the aggregate candle-power is equal to 2,710 candles. If those lamps were replaced with Nernst lamps, and two lamps fixed on each pillar in accordance with the design submitted, there would be light equal to 80 candles at each pillar, and a total candle-power equal to 8,320 candles. The annual cost for each pair of lamps would be £3, and the total cost £312 per annum. The cost for the new head and the necessary alterations would be about £2. 12s. 6d. per lamp, and would amount to £274. 12s. for the 104 lamps under consideration."

**Fire.**—A large fire broke out soon after two o'clock on Tuesday morning on the premises of the National Telephone Company at Oxford-court. We understand that the fire started in the test-room at the top of the building, and the cables fastened to the derrick over the building were burnt. The result was that some 6,000 subscribers on the Bank exchange were disconnected. Arrangements were at once made to restore communication at the earliest possible moment. A large staff was employed on this work day and night. Subsequent reports show that the damage by fire did not involve all the switchboards, which were, however, injured by water. The cause of the fire is yet to be definitely ascertained, but it is rumoured that it was due to a leakage on to some telephone wires of current from the third rail on the Underground Railway. Some of the National Telephone Company's cables are carried through the tunnels of the District Railway, so that this is possible. If this rumour proves to be correct, it will be interesting to know why the devices usually installed in telephone exchanges to guard against the possibility of such inter-connections were not effective.

**Parliament.**—Lord Balfour of Burleigh, acting chairman of committees of the House of Lords, and Mr. J. W. Lowther, chairman of committees of the House of Commons, have conferred together and have determined the House of Parliament in which the private Bills deposited this session shall originate for consideration. The following London Electricity Bills will be first heard in the House of Lords: the Administrative County of London and District Electric Power Company, Central Electric Supply, *Charing Cross and Strand Electricity Supply Corporation, *City of London Electric Lighting Company, County of London Electric Supply Company, East London and Lower Thames Electric Power, Metropolitan District Railway, *Metropolitan Electric Supply Company (Acton District), *Metropolitan Electric Supply Company (Various Powers), Metropolitan Railway, North Metropolitan Electric Power Supply, West Cumberland Electric Tramways (Extension of Time). The metropolitan Bills which will originate in the House of Commons are Baker-street and Waterloo Railway, Central London Railway, Charing Cross, Euston, and Hampstead Railway, Chelsea Electricity Supply, Edgware and Hampstead Railway, Great Northern, Piccadilly, and Brompton Railway (Nos. 1 and 2), Hammersmith, City, and North-East London Railway, London County Council (Tramways), London Southern Tramways, London United Tramways (Extension of Time), Metropolitan Electric Tramways, *Whitechapel and Bow Railway, *Walton-on-Naze Electric Supply, *Aberdare Tramways. * These Bills have now been read a second time.

Digitized by Google

**Stirling.**—The last report of the electrical engineer, Mr. A. C. Hanson, on the progress of the undertaking for the four weeks ending Jan. 21, shows that 32,715 units were generated, as against 28,061 for the same period last year. The total number of equivalent 8-c.p. lamps connected for all purposes was 16,348, as compared with 12,861 at the corresponding date last year. A sum of £1,700 is to be borrowed on electricity account. A number of electric lamps will be substituted for the gas lamps in various streets.

**New Firm.**—The Telephone and Electrical Installation Company, Mansion House-chambers, 11, Queen Victoria-street, E.C., have commenced business as telephone experts and contractors for practically all kinds of electrical installations under the management, we understand, of Mr. Horatio Bell, A.M.I.E.E., late metropolitan contract and sales manager National Telephone Company, Limited, and Mr. Stanley C. Russ, late chief of staff, metropolitan contract department, National Telephone Company, Limited.

**Electric Clocks.**—The Synchronome Company, of 32 and 34, Clerkenwell-road, whose system of electric clocks was, we are informed, the only one awarded a gold medal at the St. Louis Exposition, inform us that they have sold their Australian rights to the Synchronome Company of Australasia, Limited, of Brisbane. Mr. Alexander Knox, the managing director, who has already installed some large electrical time-circuits in Queensland with the assistance of Mr. A. G. Jackson, A.I.E.E., the technical manager, is at present on a visit to this country to perfect his arrangements with the manufacturers.

**Sunderland.**—The Electric Lighting Committee have decided to reduce the price of electricity to lighting consumers from 5d. with discount to 4½d. with discount. The present price for small motor consumers is 2½d. per unit with discount, and it was decided to give them the benefit of the maximum demand system, and charge 2½d. per unit for the first hour and 1½d. afterwards. They have also agreed to offer a reduction from 1½d. to 1¼d. per unit to the tramways, which will mean a reduction of nearly £1,000 a year. The estimate for the year ended March, 1905, shows a net profit of £4,090.

**West Hartlepool.**—An enquiry has been held into the Town Council's application for sanction to borrow £2,200 for the provision of additional plant at the electric lighting station, required in order to make provision for the increasing consumption. The borough electrical engineer (Mr. Friederichs) stated that the top load upon their plant last year was 565 kw. They had anticipated a 600-kw. load in January, but they had not been able to get the works connected which they had anticipated to supply. They now asked for sanction to borrow sufficient money to provide additional plant of 250 kw. power. The net cost of production per unit last year, exclusive of loan charges, was 1·59d., and the price for lighting 4d. per unit.

**City of London.**—The Streets Committee last night submitted a report on the proposal of the Charing Cross and Strand Electricity Supply Corporation to change the pressure from 100 to 200 volts in those portions of the western area of the City where a supply of 100 volts is now being given, the object being to make the supply in the City of uniform voltage throughout. The committee recommended that the undertakers should make at their own expense the necessary alterations to consumers' lamps, etc., and allow a deduction of 10 per cent. in the price of electric energy to consumers whose supply is changed from the lower to the higher pressure. It was also suggested that, concurrently with the alteration of the standard pressure, the undertakers should establish proper means, under the direction of the Board of Trade, of testing the public and private supply of energy.

**Football.**—On Saturday the half-yearly match between the Robertson lamp makers and the head office staff of the General Electric Company was played on the ground of the Robertson lamp makers. Owing to the fact that the lamp makers had won every year since the match was first instituted, the headquarter staff turned up in full force with a firm intention of vanquishing the lamp makers on this important occasion. The lamp makers were victorious by three goals to two, the winning goal being scored through a penalty in the last half minute of the game, much to the disgust of the headquarter staff. The football match was followed by the annual concert in the dining hall at Brook Green Works. The concert was attended by considerably over 500 people, and was, we are informed, a great success. About 30 items, including instrumental performances and songs, comic and otherwise, were gone through.

**Erith.**—The Council have agreed to supply Messrs. Callender's with further current required at the flat rate of 1½d. per unit, upon condition that the energy consumed by them for lighting purposes shall not in any year exceed 20 per cent. of the total amount of energy supplied to them by the Council. The Electric Lighting and Tramways Committee have reported that they cannot recommend the lowering of the cost of electric light to small consumers. The committee have further considered the question of the charge to be made for the lighting and maintenance of the arc lamps, which was referred back to the committee, and have reported that they see no reason to alter their previous recommendation, which they again make to the Council—viz., that as from March 31, 1904, the sum of £25 per lamp per annum be charged for the lighting and maintenance of the arc lamps in lieu of £20, previously charged. The committee are strongly of opinion that the arc lamps should be retained. Both reports were agreed to at the last meeting.

**Continental Telephones.**—During the present month every town in England where there is a first-class telephone centre will be able to telephone direct to any similar town in France. Between the two No. 1 zones the charge will be 8s. 4d., between the two No. 2 zones 12s. 6d., and between either No. 1 and either No. 2 zones 10s. 3d. per conversation. Communication will be established between the following English and French towns: Besancon, Lons-l-Saulnier, Le Mans—London (inner), Bristol, Cambridge, Leicester, Lowestoft, Norwich, Southampton, and Great Yarmouth; Fecamp—London (inner), Brighton, Cambridge, Ipswich, Lowestoft, and Norwich; Le Treport—London (inner). "Inner" London embraces the whole of the telephone exchanges within the administrative county of London, while "outer" London includes the remainder of the Post Office exchanges in the London telephone area. Communication is now practicable from London (inner as well as outer) and 20 provincial centres to 44 towns in France, in addition to many of the suburbs in Paris. From the same places in England there are telephone lines to 13 Belgian towns.

**Newport.**—The electric light installation at the parish church consists of 87 incandescent lamps, mostly of 16 c.p. The lights are fitted in the nave and chancel in groups of five on handsome wrought-iron electroliers suspended from the arches between the stone columns, and three light wrought-iron electroliers are fitted under the organ galleries and in the main porch, single lights being arranged for the galleries, vestries, and north and south porches. Special adjustable lamps are fitted to the pulpit, reading desk, and organ. The belfry and steps leading thereto are provided with small wrought-iron brackets. A distributing switchboard is fixed near the choir vestry, and this has been so arranged that the lighting can easily be graduated from two-fifths of the total light upwards, and can also be divided so that particular portions of the church may be separately lighted when so required. It is estimated that mainly owing to this arrangement the cost of lighting the church will not exceed £10 per annum. The work has been carried out to the specification under the supervision of Mr. B. H. Jenkinson, consulting engineer, of 9, Gray's-inn-square, London, by the Isle of Wight Electric Light and Power Company, whose managing engineer at Newport is Mr. E. H. Crowe.

**Islington.**—At to-night's meeting of the Council the Works Committee will report on a letter from the London County Council again calling attention to the delay in the improvement of the telephonic communication between Kentish Town fire station and the Highgate street station, and in the provision of certain fire alarms in the borough of Islington, which it is alleged are caused by difficulties between the Islington Borough Council and the Post Office as regards wayleaves, and asking that having regard to the extreme importance of the telephonic communication referred to being rendered satisfactory without any further delay, the Borough Council will make every effort to effect a speedy settlement of their differences with the Post Office. The committee will recommend that the London County Council be informed that the Islington Borough Council are not aware of any difficulties existing with the Post Office authorities with respect to wayleaves, and that any delay that has occurred in the improvement or provision of telephonic communication in the borough has not resulted from the action of the Borough Council or their officers. The electrical engineer has reported with regard to the failure on the 25th ult. of the electric light in a portion of Highbury New-park and to the danger created by the thoroughfare being left in darkness for some considerable time, that the breakdown was due to atmospheric conditions, but that steps will be taken with a view to prevent a recurrence of the failure.

**Holborn and Finsbury Electrical Exhibition.**—Holborn and the immediately surrounding boroughs are centres of considerable commercial importance, and the headquarters of many notable industries. The County of London Electric Supply Company supplies current to these districts, and there is naturally a great demand for it as a motive power to drive machinery. The exhibition, which will be held from March 20 to April 5, has been arranged with a view of familiarising users and intending users of current for power purposes; but there will also be many interesting exhibits of every form of electric lighting. We are also informed that the company are arranging for a number of exhibits, the nature of which is kept a dead secret. Altogether there are over 60 exhibitors, and we are informed that the applications for space received have largely exceeded the space available, and that the list has been closed. Among other exhibitors will be found the following firms: Babcock and Wilcox, Limited, Oriel House, Farringdon-street, E.C.; Brockie-Pell Arc Lamp Company, 60, Worship street, E.C.; Callender's Cable and Construction Company, Hamilton House, Victoria-embankment, E.C.; Crompton and Co., Salisbury House, London-wall, E.C.; Electrical Company, 122-4, Charing Cross-road; General Electric Company, 67-71, Queen Victoria-street; Johnson and Phillips, Old Charlton, Kent; Reason Manufacturing Company, Lewes-road, Brighton; Simplex Conduit Company, Westinghouse-buildings, Norfolk-street, Strand; Western Electric Company, 171, Queen Victoria-street, E.C.

**Carnarvon.**—The current at the Carnarvon electricity works was switched on last Thursday week by the Mayoress (Mrs. D. T. Lake), assisted by Mrs. W. G. Thomas, who started the engines. The plant, which provides for 10,000 8-c.p. lamps, consists of two Davey-Paxman "Economic" boilers of 7,000lb. per hour evaporative capacity; two Peache high-speed engines direct coupled to two Lancashire 100-kw. generating sets with balancer and booster; a Hart battery of 400 ampere-hours capacity, and a 96-tube Green economiser. Cables have been laid along all the main thoroughfares with extensions into the principal streets, and the supply is arranged on the three-wire continuous-current system at 230 volts. Applications have already been received for upwards of 3,000 8-c.p. lights, and 50 services have already been connected. The prices to be charged are 5d. per unit for lighting, and for power a maximum of 2½d. per unit with a sliding scale. The whole of the contract has been carried out for the Corporation by the National Electric Construction Company, Limited, who have undertaken to run the station when completed. Mr. Price F. White is the consulting engineer for the Corporation, and Mr. A. C. Goodman the resident engineer, acting under the direct supervision of Mr. E. A. Mitchell, M.I.E.E., the company's chief engineer, and Mr. D. O. Evans, A.M.I.E.E., of Bangor, the company's manager for North Wales. The building, consisting of a boiler-house, engine-room, battery-room, offices, etc., has been erected by Messrs. Heenan and

Digitized by Google

Froude, of Manchester and Worcester, under the supervision of Mr. S. Wilkinson, A.M.S.A.

**Liverpool.**—According to the annual report of the consulting electrical engineer (Mr. A. B. Holmes) on the work of the electric supply department of the Liverpool Corporation, 8,299,811 units were supplied for lighting at an average price of 3·544d.; for power purposes 2,054,679 units were supplied at an average price of 1·803d. per unit; and for tramways 18,979,133 units at 1·159d. per unit—the total supply being 29,333,623 units at an average price of 1·879d. per unit. It appears that the special efforts which have been made to reduce the working costs in the generating stations have met with satisfactory results. Mr. Holmes says that in the general expenses there were constantly increasing charges for rates and taxes, the amount last year being £14,441, as against £10,845 in 1893. The surplus of receipts over expenditure amounted to £27,575, and out of this £16,934 had been contributed in aid of the rates. Owing to various funds having to be provided for, and a material rise in the price of fuel, the engineer does not think any general reduction in charges could be prudently made, but he recommends that in order to encourage a more extensive use of electrical energy for power purposes, the 1½d. now charged after the first 3,000 units per quarter should be reduced to 1d. per unit, and that in special cases where arc lamps are used in the daytime for medical or other purposes, and not for lighting, the charge, subject to a guaranteed minimum consumption, should be made on the power scale. The engineer is of opinion that to conform to the basis of charge authorised by the Council, the price for electrical energy for the tramways for the current year should be reduced to 1·070d. per unit, with an addition at the rate of 4 per cent. for each shilling per ton paid for fuel in excess of 6s. per ton.

## PROVISIONAL PATENTS, 1905.

FEB. 20.

**3510. Improvements in and connected with devices for preventing the overcharging of electric cables.** Land und Seekabelwerke Akt.-Ges., 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, April 1, 1904, being date of application in Germany.) (Complete specification.)

**3511. Improvements in devices for preventing the overcharging of electric cables.** Land und Seekabelwerke Akt.-Ges., 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, April 1, 1904, being date of application in Germany.) (Complete specification.)

**3525. Improvements in apparatus for producing electric reactions in gases by aid of electric arcs.** Kristian Birkeland, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Feb. 20, 1904, being date of application in Norway.) (Complete specification.)

FEB. 21.

**3538. Sectional system for third or electrified rail on electric railways.** John Reed, 134, Rodsley-avenue, Gateshead-on-Tyne.

**3553. Improvements in fuse heads for electric blasting.** Frederick Render, 6, Bank-street, Manchester. (Complete specification.)

**3554. Improvements in detonator fuses for electric blasting.** Frederick Render, 6, Bank-street, Manchester. (Complete specification.)

**3560. Secondary battery.** William Morrison and Charles Caldwell Bulkley, 65, Chancery-lane, London. (Complete specification.)

**3562. Improvement in electric arc lamps.** August Eckstein and Arthur Ernest Angold, Peel Works, Adelphi, Salford.

**3567. Improvements in fog and ordinary signalling for steam and electric railways and the like.** John James Munro and Thomas Common, 11, Royal-arcade, Newcastle-on-Tyne.

**3568. Trolley change guide for electric tramway cars.** James Stewart, 20, Seedhill-road, Paisley, N.B.

**3573. Improvements in electrical means for starting prime movers for electric generators and controlling the current.** Arthur William Sclater, 182, Oxford-street, London.

**3594. Improvements in and relating to the transmission of electrical energy through space for the purpose of wireless telegraphy and the like.** Alessandro Artom, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**3604. Improvements in and relating to prepayment attachments for electricity meters.** Robert John Jocelyn Swan, 1, Queen Victoria-street, London.

**3614. Improvements in trolley heads employed in electrical traction.** Charles Edwin France, 15, St. James's-row, Sheffield.

**3616. Improvements in fuses for electric current circuits.** Ernest Francis Moy and Percy Henry Bastier, 4, Greenland-place, Camden Town, London.

FEB. 22.

**3688. Improvements in or relating to electric warp-stop motions for looms for weaving warping machines and the like.** Cecil Henry Whittington, Queen Anne's-chambers, Westminster, London. (Frederick M. Armstrong, United States.) (Complete specification.)

**3685. Improvements in and relating to ships' telegraphs and like signalling devices.** Carlo Coleatti, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**3706. Improvements in or relating to electrolytic meters, applicable to other measuring instruments or apparatus in which the (varying) level of a column of liquid is employed.** The Bastian Meter Company, Limited, Albert Edward Salisbury, Charles Orme Bastian, and George Calvert, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

FEB. 23.

**3719. Improvements in and connected with X-rays and high-frequency apparatus.** David Buchanan Selkirk, William Wotherspoon Scott, and William Cousin, 154, St. Vincent-street, Glasgow.

**3726. Improvements in or connected with electric wires.** Albert Edward Patrick, Prudential-buildings, Corporation-street, Birmingham.

**3759. An electrical railway signal.** Victor Charles Badois, Victoria-street, Windsor.

**3762. Improvements in and relating to electrical circuit-breaker mechanism.** Walter Edward Barton, 55, Chancery-lane, London.

**3784. Improvements in or relating to wireless telegraph detectors and telephone electrophone and like receivers.** Hahnemann Adolphus Cutmore, 315, High Holborn, London.

**3795. Improvements in the electric lighting of railway and tramway carriages.** J. Stone and Co., Limited, and John Robert Quain, 77, Chancery-lane, London.

**3796. Improvements in accumulator batteries.** J. Stone and Co., Limited, and John Robert Quain, 77, Chancery-lane, London.

**3815. Improvements in electric potential indicators.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**3816. Improvements in and relating to gearing especially applicable to power-operated electric switches.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**3829. Improvements in and relating to electrical ignition devices for internal-combustion engines.** John Albert Cole, 70, Chancery-lane, London.

**3830. Improvements in and relating to electrical ignition devices for internal-combustion engines.** John Albert Cole, 70, Chancery-lane, London.

FEB. 24.

**3855. Improvements connected with the starting, reversing, accelerating, and stopping of electric motors.** Ernest Sherwood Woollard Moore and William Brabiner Bennett, Prince's-chambers, Wolverhampton.

**3857. Controlling devices for electric motors.** Wallace Fairweather, 65, Chancery-lane, London. (Diehl Manufacturing Company, United States.)

**3867. Electrical apparatus for automatically controlling the pressure of steam in boilers.** Ralph Lomax and John Tomlinson, 57, Barton-arcade, Manchester.

**3876. Improvements in inverted incandescence lamps.** Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Julius Pintsch, Germany.)

**3877. An improved electric incandescence reading lamp.** Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Julius Pintsch, Germany.)

**3885. Improvements in electric trolley harps.** John Hensley, 3, Upper Vernon-street, London. (Date applied for under Patents Act, 1901, May 5, 1904, being date of application in United States.) (Complete specification.)

**3894. A new or improved accumulator plate.** Eugene Victor Gratzs, 81, High Holborn, London. (Complete specification.)

**3899. Improvements relating to motor meters for continuous and alternating electric currents.** Wilhelm Köstermann, 37, Essex-street, Strand, London.

**3912. Improvements in the manufacture of filaments for incandescing electric lamps.** Jack Randall Crawford, Clun House, Surrey-street, Strand, London.

**3913. Improvements relating to apparatus for enabling telephonic and telegraphic messages to be transmitted over the same line.** Carlo Turchi and Edmondo Bruné, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, April 2, 1904, being date of application in Italy.) (Complete specification.)

**3918. Improvements in and relating to electric fans.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

FEB. 25.

**3957. An improved apparatus for the automatic ignition of gas, gaseous mixtures, or the like by means of an electric current.** George Hill, The Grove, Ashton-on-Mersey. (Complete specification.)

Digitized by Google

**3968. Improvements in electricity meters.** Harold Thomas Brown, Electric Supply Company, Limited, Thompson's-lane, Cambridge.

**3978. Improvements in electrical alarm contacts for door locks.** Richard Blessin, 40, Chancery-lane, London.

**3979. Improvements in supporting devices for electric conductors.** Budd John Jones, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, March 14, 1904, being date of application in United States.) (Complete specification.)

**3994. Improvements in or relating to electrical troughs, conduits, or the like.** John James Bate, 6, Lord-street, Liverpool.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published March 16.*

1904.

**1494. Alternating-current dynamo-electric machines.** Latour. (Date applied for under International Convention, Jan. 21, 1903.)

**4116. Electrically-controlled lifts and hoists.** Chaudoir.

**5104. Method of increasing the discharge energy of electrical vibration systems.** Thomson. (Ges. für drahtlose Telegraphie m. b. H.)

**8077. Trolley heads of electric tramcars and the like.** Thompson.

**8401. Alternating electric current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**8404. Alternating electric current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**8477. Incandescent electric lampholders.** Rees.

**8686. Primary galvanic battery.** Delafon.

**8984. Manufacture of positive electrodes for galvanic batteries.** Delafon.

**9117. Dynamo-electric machines.** British Thomson-Houston Company, Limited. (General Electric Company.)

**9372. Armatures for dynamo-electric machinery.** Hills, Urquhart, and Honey.

**9373. Brushes for dynamo-electric machinery.** Hills, Urquhart, and Honey.

**9565. Electric tramway or railway vehicles.** Raworth.

**11262. Method for the transmission of sound to long distances and telephonic apparatus therefor.** Tardieu.

**11777. Electrical tumbler and like switches.** Lawton and Whatson.

**17939. Electric trolleys or collectors for electric traction.** Lauvernier.

**19242. Electric light fittings.** Lea and Mitchell.

**22326A. Controllers for electric current.** Justice. (Voltage Controller Company.) (Date applied for under Patents Rule 9, Oct. 17, 1904.)

**22342. Arc lamp electrodes.** Körting and Mathiesen Akt.-Ges. (Date applied for under International Convention, Oct. 31, 1903.)

**22813. Scraper for electromagnetic separator.** Ernst Heinrich Geist Elektricitäts Akt.-Ges. (Date applied for under International Convention, Jan. 18, 1904.)

**24675. Electric brakes for trams and other vehicles.** Ransford. (American Electric Brake Company.)

**27916. Locking apparatus for watchmen's electric controls and the like.** Hindersin.

**28469. Electric arc lamp.** Fairweather. (Marquette Electric Company).

**29063. Insulators and protective devices for overhead electric conductors.** Giraud. (Date applied for under International Convention, April 14, 1904.)

**29064. Safety devices for overhead electric conductors.** Giraud. (Date applied for under International Convention, April 14, 1904.)

**29397. Pendant electric fixtures.** Lake. (Bradshaw, Keough, Keough, and Keough.)

**29538. Electric circuit closer for fire-alarms.** Bamiller and Weisensale. (Date applied for under International Convention, May 7, 1904.)

## NOTES.

**Royal Institution.**—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, his Grace the Duke of Northumberland, K.G., D.C.L., F.R.S, president, in the chair. Mr. W. K. Appleton, Dr. G. H. Burford, Mr. W. S. Burns, Mrs. Close, Miss Donaldson, Dr. G. E. Haslip, Lady Hodgson, Mrs. Laye, Mr. J. B. Tapling, Lieut.-Colonel Vincent Wing, C.B., Mr. P. von Fleischl, and Mr. J. E. Wolfe were elected members.

**Telegraph Wires.**—Amongst the resolutions passed by the Association of Chambers of Commerce last week was one relating to telegraphic communication. The resolution urged the Government to establish, without further delay, additional cables between the United Kingdom and the Continent, and more direct wires between the chief commercial centres of this country and Continental Europe; and it also maintained that it was of urgent importance that the Postmaster-General should at once be empowered to lay all trunk wires underground.

**The Institution.**—The first annual dinner of the Students' Section is to be held at the Holborn Restaurant on Thursday, the 16th inst., at 7 for 7.30 p.m. Mr. H. D. Symons, chairman of the section, will occupy the chair; and the president, Mr. Alexander Siemens, has honoured the committee by accepting an invitation to attend as the guest of the evening. All students who can possibly attend are particularly requested to do so. Early application for tickets should be made to the hon. secretary, Mr. A. G. Ellis, 177, Warwick-road, Kensington, W.

**Electrically-Driven Mills in Mexico.**—The *Pall Mall Gazette* has an article on the manufacture of cotton goods in Mexico. It seems from the statements of our contemporary's correspondent that the competition both of England and the United States for low-grade cotton goods is being killed by the Mexican home industry. The success of the Mexican mills is attributed to their being electrically driven from water power and also to cheap labour. Besides this, there is a high tariff on imported material which protects the rapidly growing industry. The fact remains, however, that the millowners in Mexico have adopted electric driving and all the latest improvements. As was stated last week, Lancashire mill-owners are experimenting largely in the same direction, but the saving from electric driving will hardly make up for the Mexican protective duties.

**Therapeutics and Lay Practitioners.**—The action of a firm of chemists and surgical instrument makers in undertaking a skiagram of a case of suspected mediastural tumour, after a medical practitioner had been engaged for the purpose at a higher fee, elicits the disapprobation of the *Lancet*. Our contemporary objects, in fact, to laymen undertaking X-ray work for therapeutic purposes at all, and expresses astonishment at finding the practice followed by a firm of good standing. Some time ago a physician ventilated a grievance in the same journal arising out of the electrical treatment of patients by laymen, which complaint, as remarked on the occasion, seemed to us ill-founded; but if there was any justification for the protest then, we cannot see that it holds good in the present case, seeing that X-ray photography does not call for medical knowledge. Indeed, we rather think the boot is on the other leg, and that doctors sometimes encroach upon the legitimate sphere of X-ray photographers.

**Hydro-Electric Plants for Railways.**—A paper on "The Use of Pacific Coast Water Powers in the Electrical Operation of Railroads" was recently presented to the Pacific Coast Railway Club by Mr. Robt. McF. Doble. The author alluded to the magnificent source of power offered by the waterfalls which are distributed at frequent intervals all the way from Southern California to British Columbia, and referred particularly to the San Francisco North Shore Railway. This line is of special interest as being the only third-rail system in California, and because of its being operated from the Alto sub-station, which is the terminus of one of the longest transmission lines in the country. The author concluded his paper by enumerating the distinguishing characteristics of some of the leading hydro-electric systems of California, special reference being made to the new De Sabla power-house of the California Electric Corporation, where there is now operating an 8,000-h.p. tangential water-wheel, the largest single water-wheel ever constructed. This station regularly supplies power to San Francisco and other points over 300 miles distant.

**Canals versus Railways.**—At a meeting of the Society of Engineers on Monday Mr. B. H. Thwaite read a paper on "The Transport Possibilities of our Inland Navigable Waterways." The author indicted the railway companies for suppressing canals, and the Government for indifference to this absorption, which had resulted in a depreciation of canal properties by many millions of pounds and the destruction of a trunk system of waterways that, if restored, would go far by its low charges towards securing a revival of our agricultural prosperity. He advocated the Government confiscation and ownership of canals. Hundreds of miles of our canals were, he said, little better than elongated ditches of mud and stagnant water, and £20,000,000 would secure for the State a splendid transport property. For the carriage of cattle, agricultural products, raw material for factories, and generally for the carriage of heavy freights at slow speeds where time was not essential, he considered that canals would be of the greatest advantage. He mentioned that by electric traction 24½ tons could be conveyed for one mile for 1d. The various chambers of commerce have devoted considerable attention of late to the resuscitation of our canals, but for the present the subject has stopped short at recommendation. The railway companies prefer to keep the matter in the background, and the Government does not seem disposed to bring any pressure to bear upon them, though the proposal at least merits thorough investigation.

**Compulsory Greek.**—The university on the Cam has decided upon the retention of Greek as a compulsory subject for the entrance examination. This verdict was arrived at by the substantial majority of 507 in an electorate of 2,611. To oppose the substitution of science or mathematics for Greek, rural parsons from divers obscure corners of the kingdom made a pilgrimage to their Alma Mater, the clerical vote being very much in evidence. Were no other question involved than the contention of the compulsory Greek party that the Hellenic tongue must be the basis of intellectual culture, the attitude of that party might perhaps be tenable; but when eminent educationists declare that the 12 months' "cramming" in Greek which enables a student to pass the "Little Go" is of little or no value, the argument becomes illogical. But, apart from this, science has acquired a position of transcending importance, and it is difficult to see how without some knowledge of it anybody can to-day lay claim to the higher education. The conservatism of our ancient seats of learning is traditional, though the younger University created a departure when Girton was incorporated with it; but no one can fail to have been struck by the change in the conditions of education that has occurred during the last two or three decades.

Greater accessibility has assembled on the Isis and the Cam, a far more diversified representation of the country's youth than was the case half a century ago, when Oxford and Cambridge turned out ecclesiastics and pedagogues who were presumed to know their Homer and Xenophon, and often did, and embryo squires who were sometimes supposed to, and generally didn't. Cherished traditions die hard, but the claims for reform daily grow in strength, and we feel constrained to believe that the vote just recorded will only defer the inevitable.

**Wireless Telegraphy.**—We have received from Mr. A. Artom an extract from the *Proceedings* of the Royal Academy of Lincey, in which his new system of wireless telegraphy is described. The feature of Mr. Artom's work consists in so arranging his oscillators as to produce circularly or elliptically polarised rays of electric power. He has been at work on this subject for a number of years, and described briefly the lines of his investigations in a communication presented to the same academy in March, 1903. The advantage of the system lies in being able to produce a more intense electromagnetic field in a given determinate direction. This secures economy in power, but what is more important, tends to prevent the reception of signals in any direction but the one in which the message is being dispatched. A history is given of the experiments carried out by the author during four stages. In each stage the distance over which the experiments were conducted was increased, until for the fourth period, which comprised the autumn and winter of 1904, signals were being sent between a station at Monto Mario, Rome, and the island of Maddalena, a distance of about 160 miles. Experimenting between these points, the author obtained clear signalling, and proved that the range could be extended to nearly 200 miles on the same line. Notwithstanding this fact, the signals could not be detected on the island of Ponza, which lies about 60 miles to one side of the direct line between the two stations. The experiments in question were carried out with temporary plant, but clearly proved the success of the author in working with circularly or elliptically polarised rays.

**Aluminium Anode Films.**—An abstract of a paper read before the American Physical Society by Mr. C. McC. Gordon on the capacity and resistance of aluminium anode films, which have been the subject of numerous investigations in recent years, appears in the February issue of that institution's *Journal*. The author remarks that the thickness, the chemical nature, the resistance, the specific inductive capacity of these films, the voltage at which they break down, and the variations in their properties with the nature of the electrolyte, are questions concerning which the evidence is varied and in many cases apparently contradictory. Most of the measurements heretofore made have been carried out with the use of direct currents. The use of alternating currents with the Wheatstone bridge possesses advantages over the direct-current methods, in that the capacity, resistance of the film, and the resistance of the electrolyte can be independently measured at the same time. The author's recent experiments with the latter method show that: (1) The capacity of the film is inversely proportional to the volts used to form the film. It is to be inferred from this that the thickness of the film is proportional to the volts applied in its formation. (2) For water solutions, the capacity of the film varies but slightly with the nature of the electrolyte, provided, of course, the electrolyte is such as to form a film at all noticeable. This is not in accord with the theory recently advanced by Mott—*i.e.*, that the films would be thinner the greater the valence of the acid radical of the electrolyte. (3) The capacity of the films formed in molten electrolytes is much less than those of water solutions. (4) The capacity of the films in molten electrolytes increases rapidly after the voltage applied to form the film is taken away, indicating a rapid dissolving of the film in molten electrolytes. (5) The resistance of the films is much less than is given by many investigators.

**The Telephone Question.**—On Monday last the Postmaster-General (Lord Stanley, M.P.) received a deputation representing municipalities owning and working telephone systems. The Lord Provost of Glasgow headed the deputation, which desired to show how such municipalities would be affected by the proposed purchase agreement between the Postmaster-General and the National Telephone Company. The meeting was private, but we understand that the following points were dealt with by the deputation: (1) That the partial purchase of the London system of the National Telephone Company and the postponement of the purchase of its provincial systems was to be deprecated, because it would enable the company to devote greater energy and capital towards crushing out the municipal telephone system in the provinces; (2) that their experience had proved that it was not essential for the telephone service to be conducted as a national monopoly, for from 97 to 98 per cent. of the total calls were local; (3) that the Post Office ought to administer the acquired national system in friendly competition with the licensed municipalities and give greater encouragement to other municipalities to enter the field; (4) that in the event of the postponement of a settlement the Post Office ought to enter into vigorous competition with the company throughout the kingdom, assisted by the co-operation of municipalities, in order to avoid the danger of an inflated price being forced upon the Government; and (5) with regard to the possibility of extending the company's license it would meet with strenuous opposition from the municipalities, it would prolong the existing unsatisfactory condition of telephone affairs in this country, enable the telephone monopoly to reach such gigantic proportions as ultimately to render a reasonable settlement of the question impossible, and create a menace to the commercial interests of the kingdom. Lord Stanley, in reply, expressed himself as being in favour of the nationalisation of the telephones, and suggested a further interview with the municipal telephone undertakers to discuss this and other points.

**Publications Received.**—"Practical Methods of Electro-Chemistry," by F. M. Perkin. (London: Longmans, Green, and Co. 6s.) The author has compiled a text-book on this subject, based upon experimental work carried out under his own supervision. It is divided into three parts, the first dealing with electrolysis and the general aspects of electro-chemistry, the second with electro-chemical analysis, and the third with electrolytic preparations. Much care has been exercised in the preparation of the volume, which should do much to promote the commendable object the author has in view—stimulating interest in this branch of science.—The *Journal* of the Franklin Institute (Philadelphia) for February contains a paper on "Rolled-Steel Car Wheels," by Mr. S. H. Vauclain. Another paper by Mr. L. M. Haupt, entitled "A Menace to the New York Harbour Entrance," deals with the peculiar physical conditions existing on the bar extending from Sandy's Hook to Coney Island, and suggests a method of so modifying the ebb current passing out at Gedney's Channel as to increase the depth by natural erosion. Mr. J. M. Matthews deals with "The Sulphur Dyes," and there is a letter from a correspondent on the proposed amalgamation of the Massachusetts Institute of Technology with Harvard

Digitized by Google

University.—We have received a copy of the Institution's *Journal*, dated February, which contains the President's inaugural address, and the following papers, with the discussions: "Hydrodynamical and Electromagnetic Investigations regarding the Magnetic Flux Distribution in Toothed-Core Armatures," by Prof. Hele-Shaw and Messrs. A. Hay and P. H. Powell: "Studies in Magnetic Testing," by Mr. G. F. C. Searle; "The Use of Iron in Alternate-Current Instruments," by Dr. W. E. Sumpner (Birmingham). A special feature of this issue is a report of the proceedings at the St. Louis Congress, with the discussions on several of the papers. There are also the address at St. Louis to the American Institute by Mr. B. J. Arnold, president, and the inaugural addresses of the chairmen of the Glasgow, Dublin, Leeds, Manchester, and Newcastle Sections.

**Single-Phase Railway.**—The Indianopolis-to-Cincinnati single-phase railway is in operation as far as Rushville, a distance of 41 miles, and the construction of the remainder is being rapidly pushed forward. The power station from which it is intended to operate the line is located at Rushville. Energy is generated at 33,000 volts, and is reduced to 3,300 volts at the points of transformation. Within the city of Indianopolis, a distance of some three miles, the cars will be run over existing lines, and will be operated by direct current at 550 volts. Within the city of Rushville alternating current at the same potential will be employed. On intervening sections the line voltage will be 3,300 single-phase alternating current at 25 cycles. The trolley equipment is of interest as being of the type which is proposed for the London, Brighton, and South Coast Railway Company. The rails run along a private right-of-way, except where they emerge upon the highways of large towns. Along the private right-of-way the trolley wire is suspended from poles set in the centre of the grade 100ft. apart, with an iron bracket looped at the end so as to carry a large flat porcelain insulator, over the top of which runs a $\frac{7}{16}$in. steel strand cable or "messenger" wire, drawn tight. The No. 000 grooved copper trolley wire is carried 8in. under the messenger cable, to which it is attached every 10ft. with specially-made steel clamps, the construction being of the catenary suspension type. Under these conditions danger from breakages of the trolley wire is reduced to a minimum. The insulators are large and strong, and are not likely to break, but if they should, the steel cable would remain suspended from the top of the bracket. As the trolley is attached to the steel cable every 10ft., breakages will be very infrequent, and if one should occur, not more than 10ft. of the trolley would be loose. The catenary construction provides a practically level trolley with no sudden bends at the insulators, as is found with the ordinary suspension, a point which is a great advantage to fast-running cars. The trolley wire is suspended 18ft. above the top of the rail. Where the track is in the public streets, the poles are set on the sides of the streets, and the trolley is suspended from span wires; otherwise the construction is the same as along the private right-of-way. The cars are scheduled to run at a speed of 30 miles per hour, but for the through service there will be trains running at between 50 and 60 miles an hour.

**Electric Lighting in Paris.**—The technical commission appointed to report on the future *régime* of electricity in Paris has recently issued its report, which deals solely with the technical side of this important question. The conclusions of the commission are summarised as follows by the recorder, Mr. R. V. Picou. The commission considers that the most convenient technical scheme for the distribution of electricity in Paris is one which consists (*a*) in the production of high-tension polyphase currents at a frequency of 50 periods per second in several stations situated outside the city on the banks of the Seine; (*b*) the transformation of this current in sub-stations, of which those serving the central areas will distribute with continuous current on the three-wire system at 110 volts between the inner conductor and either of the outers. The sub-stations in the areas which are less densely populated will distribute alternating current at 110 volts; (*c*) the direct transformation from high voltage to low voltage on the consumer's premises will be restricted to special conditions where motive power is important, or where the demand is infrequent or irregular. In the second place, the system of charges considered the most logical consists in the adoption of a sliding scale, such that the sum received from the consumer is in proportion to that spent for supplying him. This sliding scale is to be based on the size and reading of the consumer's meter, thus avoiding any interference with the consumer's installation. Thirdly, the changes in the present systems which the execution of the programme will necessitate will have to be gradually carried out over a certain number of years, and the commission advises that the transformation should be commenced in those quarters where the demand for power is largest. In other parts of the report a number of technical subjects are treated, to which we hope to refer more in detail elsewhere. For instance, the commission advises the use of steam-turbines in the three new generating stations to be constructed, and advocates that the power of the turbo-generators should be at least 5,000 kw. The importance of having a good vacuum with turbines led to the recommendation that the station should be placed on the banks of the Seine, as the canals around Paris do not contain sufficient cooling water for the large generating works contemplated. Three independent stations are recommended, in order that continuity of supply may be assured. The other features in this report we leave for future attention.

**"Electrics."**—We have received from the South Wales Electrical Power Distribution Company, No. 1, vol. 1, of *Electrics*. This publication, issued by the company, is being circulated amongst the users of power in South Wales and Monmouthshire with the object of giving general information both as to what the company is doing and as to the use of electricity for power purposes. The information given is not of an elementary order, and is such as will appeal to the engineers responsible for commercial undertakings. There is, of course, a considerable amount of information as to what the South Wales Power Company are doing in their various generating stations and sub-stations, and the information under this head clearly shows that rapid progress is being made. We are pleased to note that in laying down their main cables the company is, wherever possible, duplicating the routes by which any consumer can be supplied. In some cases the system goes even further, and provides three ways by which the supply can be given, so that any feeder may be closed down for testing or for making connections for the extension of supply. The question of overhead mains is also being considered by the company's engineer, and routes have been surveyed from Cwmbran to Treforest, and thence on to Neath. Application is shortly to be made to the Board of Trade for permission to run these mains overhead for extra high-tension supply. If this is granted, a number of consumers will be reached who could hardly be profitably supplied by means of underground cables. The first issue of *Electrics* also gives some useful editorial notes on special applications of electricity. Amongst the uses for which it is advised is the haulage of rubbish from the South

Digitized by Google

Wales collieries up to the top of the rubbish tips. This class of haulage gear is specially suited to electric driving, as is clearly pointed out. Another editorial article on the cost of electricity should receive the attention of would-be consumers. The object of it is to show the inaccuracy of estimates of cost arrived at by multiplying the maximum power of motors by the number of hours they are worked per week. The editor points out that the weekly cost of energy will usually represent less than one-quarter of the amount so calculated, or at the most one-half, owing to the fact that the maximum power taken is always much less than the aggregate maximum powers of the motors installed. The paper, if circulated regularly, should do much to extend the use of electricity in the districts supplied by the South Wales Electrical Power Company.

**Railway Accidents in the States.**—The report of the Inter-State Commerce Commission for the three months ending September last gives the number of people killed in train accidents throughout the United States. These returns are made from reports of the companies, which show that the number of persons killed was 411 and those injured 3,747. Including accidents sustained by employés while at work and by passengers in getting on and off cars, etc., the total number of casualties for that quarter of the year was brought up to 14,239, of which 1,032 were killed and 13,207 were injured. These figures mean that in the course of a single year, were this rate of maiming and killing sustained, the American railways would be directly or indirectly accountable for the death of 4,128 and the more or less serious injury of 52,828 people. The bulletin of the commission says that the quarter under review may, as a whole, be termed the most disastrous on record. Of the 228 passengers and 183 employés killed in train accidents, 217 cases are accounted for by six accidents, and these 217 were nearly all passengers. In one case of derailment, 88 people were killed; in one collision, 63 were killed; in another, 24; and two other collisions accounted respectively for 18 and 16 deaths. Our contemporary the *Scientific American* has an article in which enquiry is made as to why these casualties are so numerous, especially when compared with the English returns. It points out that the number of people killed and injured is not the true criterion of the safety of a railway, but rather the number of accidents which happen within a given time. Tested on this basis, the record for the three months in question show that there were 1,439 collisions and 1,321 derailments, of which 232 collisions and 137 derailments affected passenger trains. Our contemporary explains its views as to why the American railways have so many more accidents than those in this country, and lays the chief blame on the continual change in the personnel both of the employés and in the directorate of the various lines. In consequence of this there is a great want of familiarity with the local conditions, which, without doubt, contributes to the accidents. It seems to us, however, that it is to the signalling systems that the greatest number of accidents can be attributed. Even in this country, where the block system obtains, we have accidents due to the neglect of signals. In the States, where on many lines there is no attempt at block working and a penalty if drivers lose time, a premium is placed on quick running, and there seems to be little attempt to safeguard the public. These conditions and a frequent change of staff furnish the true explanation of the return in question.

**Electric Smelting of Iron and Steel.**—Mr. F. W. Harbord, A.R.S.M., F.I.C., read an interesting paper before the Faraday Society on Monday last on "Recent Developments in Electric Smelting in connection with Iron and Steel." The author was a member of the commission appointed by the Canadian Government to investigate the different thermo-electric processes for smelting iron ores and the manufacture of steel at work in Europe. His paper before the Faraday Society was in the main a *résumé* of the report of the commission describing the various furnaces which were inspected. Of the five works visited, two were in Sweden, two in France, and one in Italy. We have previously referred to the work of the commission, which dealt with the essential features of a variety of electric furnaces. The results of the investigations are ably summed up in the following conclusions, which represent the author's opinion with respect to electric smelting in the present state of the art. There is no doubt that developments and improvements will greatly modify some of these conclusions in the near future: (1) Steel equal in all respects to the best Sheffield crucible steel can be produced, either by the Kjellin or Hèroult or Keller processes, at a cost considerably less than the cost of producing a high-class crucible steel. (2) At present structural steel, to compete with Siemens or Bessemer steel, cannot be economically produced in the electric furnaces, and such furnaces can be used commercially for the production of only very high-class steel for special purposes. (3) Speaking generally, the reactions in the electric smelting furnace as regards the reduction and combination of iron with silicon, sulphur, phosphorus, and manganese, are similar to those taking place in the blast furnace. By altering the burden and regulating the temperature by varying the electric current, any grade of iron, grey or white, can be obtained, and the change from one grade to another is effected more rapidly than in the blast furnace. (4) Grey pig iron, suitable in all respects for acid steel manufacture, either by Bessemer or Siemens processes, can be produced in the electric furnace. (5) Grey pig iron, suitable for foundry purposes, can be readily produced. (6) Pig iron low in silicon and sulphur, suitable either for the basic Bessemer or the basic Siemens process, can be produced, provided that the ore mixture contains oxide of manganese, and that a basic slag is maintained by suitable additions of lime. (7) It has not been experimentally demonstrated, but from general considerations there is every reason to believe that pig iron low in silicon and sulphur can be produced even in the absence of manganese oxide in the iron mixture, provided a fluid and basic slag be maintained. (8) Pig iron can be produced on a commercial scale at a price to compete with the blast furnace, only when electric energy is very cheap and fuel very dear. On the basis taken in this report, with electric energy at 10dol. (41*s.* 8*d.*) per electrical horse-power year, and coke at 7dol. (29*s.* 2*d.*) per ton, the cost of production is approximately the same as the cost of producing pig iron in a modern blast furnace. (9) Under ordinary conditions, where blast furnaces are an established industry, electric smelting cannot compete, but in special cases, where ample water power is available, and blast-furnace coke is not readily obtainable, electric smelting may be commercially successful. The author adds that it is impossible to define the exact conditions under which electric smelting can be successfully carried on. Each case must be considered independently after a most careful investigation into local conditions, and it is only when these are fully known that a definite opinion as to the commercial possibilities of any project can be given.

**Mr. Marconi's Lecture.**—The Royal Institution was early overcrowded on Friday last, when Mr., or, rather, the Chevalier Marconi delivered his lecture on "Recent Advances in Wireless Telegraphy." The Duke of Northumberland presided, and among those present were Lord Kelvin, Lord Rayleigh, Sir Thomas Sanderson, Sir James

Digitized by Google

Dewar, Sir W. J. Farrer, Sir James Crichton-Browne, Sir William Crookes, Prof. Fleming, and Prof. H. E. Armstrong. Mr. Marconi observed at the outset that the recent improvements in wireless telegraphy included means to prevent interference and secure independence of communication, to increase the distances over which communication was possible, and to obtain greater efficiency and accuracy. He thought the difficulty regarding liability to interference had been exaggerated by the non-technical mind; the expert telegraphist knew that the same thing was possible with ordinary telegraphy, but that it was prevented by rules and regulations devised to that end. In some instances—such as a shipwrecked vessel calling for assistance—it was a distinct advantage that the messages should be received by a number of other ships or stations; but as this interference must in some cases be recognised as a drawback, he had devised a method of obviating it. This method, as is now well known, consists of the syntonisation of the apparatus at the various stations to different periods, by which it is now possible to transmit messages to each one of them without the others being affected, and even five years ago it was possible to send and receive several messages simultaneously without one interfering with another. Mr. Marconi then dealt with receiving apparatus, and exhibited his magnetic detector, which is to supersede the coherer. He stated that the alterations effected in the detector as the result of experience render high speed and automatic transmission attainable. At first the detector had the disadvantage that it could not be made to actuate a recording or writing instrument, the current impulse with which it worked being too rapid to have any appreciable effect on the tongue of a relay, but by altering the circuits and the character of the iron employed in the magnets, the impulse had been slowed down, so that it was possible to operate a relay, and, therefore, a recording instrument. With this arrangement the lecturer stated that a speed of 24 words per minute had recently been maintained over a distance of 152 miles overland. The audience witnessed the transmission of a message, using the magnetic detector, and a Wheatstone receiver rolled out the tape with the words printed in Morse characters. Dealing with long-distance transmission, the lecturer adhered to his optimistic attitude, expressing confidence that in a short time it would be demonstrated that transmission across the Atlantic was not only practicable, but trustworthy, and the method so economical as to be within the means of the majority. Besides this, he hazarded the assertion that Lord Kelvin's prediction as to wireless communication with the Antipodes might be realised. Referring to the differences in transmission by day and night, Mr. Marconi stated that these were only noticeable over long distances, the range by night being much longer than that by day, as clear sunlight appeared to act as a fog to the Hertzian waves; but the lecturer took the opportunity of reminding the audience that clear sunlight and blue skies were not general in this country. In conclusion, Mr. Marconi gave some particulars showing how the use of his system has become extended. The announcement as to the speed atttained with the magnetic detector is interesting, especially in view of the little discussion that ensued upon Captain Lionel James's recent paper before the Society of Arts. It will be noticed that the speed mentioned is somewhat less than that which Captain James announced he had attained with the de Forest system in the Far East.

**Closing Bulkhead Doors by Electricity.**—A method of electrically operating bulkhead doors and armoured hatches on warships, which has superseded the pneumatic and hydraulic systems after years of costly experiments with the latter, is described in the *Electrical World* of New York. This apparatus, which is known as the "long-arm" system, is now in working order on the "Colorado" and "Pennsylvania," the new 13,500-ton armoured cruisers. The mechanism consists of (1) an emergency station of two parts, one a watertight case containing the mechanism for controlling the circuit running to each door or hatch gear for closing the same, and the lamps to indicate the closure, the other case containing the fuse box, in which each wire is supplied with the proper fuse; and (2) the power doors or hatch gears, supplied with the three independent mechanisms: (*a*) the switch by which a man at any door can open and close it at will from either side; (*b*) the switch, operated from the emergency station, by which the door is closed upon the approach of danger; (*c*) the limit switch, by means of which the current supplying the motor which provides the power for closing and opening the doors, is cut off when the motor has closed and locked, or has encountered an obstacle to full closure. This switch has mechanical connection with the door or hatch plate, and is so arranged that it will cut off the current from the motor, and thus prevent blowing out of the fuses. An interesting improvement of this part of the mechanism is one by which the switch is made to again close the circuit to the motor and thus start the door toward its grooves after an obstruction is removed—*e.g.*, when an inflow of water washes away coal obstructing a bunker opening. The door and hatch gear motors are direct-current, reversible, iron-clad, bipolar machines of light and compact construction for intermittent service. They are entirely enclosed in watertight cases, and capable of carrying large overloads without heating or injury. The mining is very simple, comprising one twin conductor by which the emergency station is connected with the ship's mains, one twin conductor by which the controller on each door and hatch gear is connected with the emergency station, and one twin conductor connecting the controller on each hatch gear or door with the ship's mains. To explain the operation of the system our contemporary gives a concrete example. Suppose that the "Colorado" is in danger of being rammed, or that her hull has been punctured by a torpedo. The officer of the deck or the one first aware of the danger will "press the button" of the emergency station, immediately releasing the gearing driven by a spring and controlled by an adequate escapement. This gearing then closes the circuit for operating the emergency switch in the controller of each door or hatch gear. It does not start all the motors at the same time, thus avoiding the necessity for a large supply of current. It starts the doors one after the other at intervals of about three seconds, so that 25 doors and hatch gears can be closed in 75 seconds from each emergency station without more than six motors being in operation at any one time. As each door makes a complete closure it automatically completes a circuit running to the emergency station and is there connected with a small incandescent lamp, located back of each of the discs around the edge of the emergency station. Each disc is numbered to correspond to a door, so that the officer in charge can tell by a glance at the station whether or not all the doors have closed. If any one door or hatch plate has not closed, the fact is immediately observable, and the location of the trouble is known by reference to a diagram at hand showing the location of all the power doors and hatchways. This system complies with all the regulations of the Navy Department, and presumably has been found to give satisfaction, as it is stated that 13 other cruisers and battleships now building will be similarly equipped.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

*(Continued from page 302.)*

SIMPLE TWO-CIRCUIT (OR WAVE) WINDINGS.

**General Derivation.**

We pass now to a class of winding which is essentially a multipolar development of simple bipolar *drum* windings, and although rings may be wound after the same fashion, the ring diagram does not in this case simplify the study of the drum. These windings are called by Parshall and Hobart *two-circuit* windings, and their development may be traced as follows: When in Fig. 7 we obtained from a six-pole ring winding the corresponding six-pole drum, we found that rule for connecting up which is given on page 150, and which resolves itself into connecting a conductor under a north pole to one under a south pole, and then returning to the next conductor but one under the north pole from which we started. But when this process is carried out for a multipolar machine the question immediately suggests itself, Why not start from a conductor under a north pole, pass to one under the next south pole, and then (instead of returning) pass to a conductor under the next north pole, and so on? It is rather interesting to see what will happen if we do this.

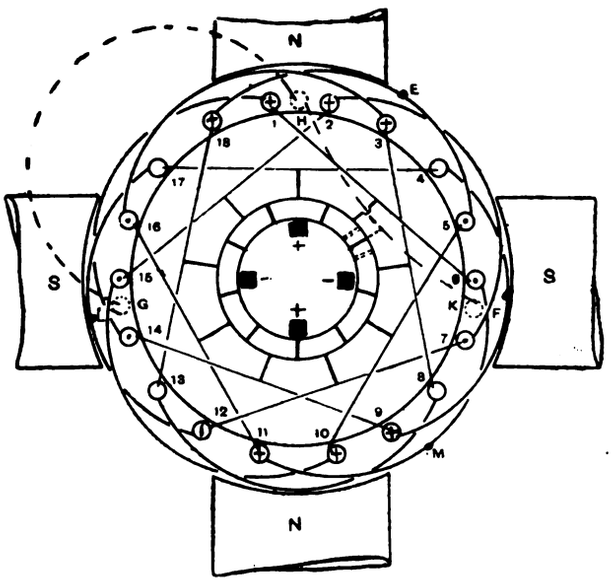

FIG. 14.

Fig. 14 is a diagram of a four-pole machine having 18 inductors on the armature. If it were a multiple-circuit winding, we should start from conductor 1, pass to 6, back to 3, and so on. Instead of this, let us start from 1, pass to 6, and then go to 11, and from 11 to 16, etc., until the winding is complete. The winding scheme is as follows:

1—6—11—16—3—8—13—18—
5—10—15—2—7—12—17—4—
9—14—1.

It will be seen that the winding closes properly—*i.e.*, is re-entrant.

From the position of the inductors in the diagram, it is also seen that at the particular instant inductors numbered 18, 1, 2, 3, 9, 10, and 11 have electromotive forces induced in one direction, whilst those numbered 16, 15, 14, 5, 6, and 7 have electromotive forces induced in the opposite direction.

Let us then ascertain what is the result of this system of connection, and where we should place the brushes.

**Use of Developments.**

In all the types of winding hitherto discussed, we have been able to see clearly the answers to these questions by reference to the corresponding ring type. Here, since this method is unsuitable, we must have recourse to what are termed developments or developed drawings. According to this method the winding is usually supposed to be cut through at one point, removed from its core, and pictured then as though laid open on a flat surface.

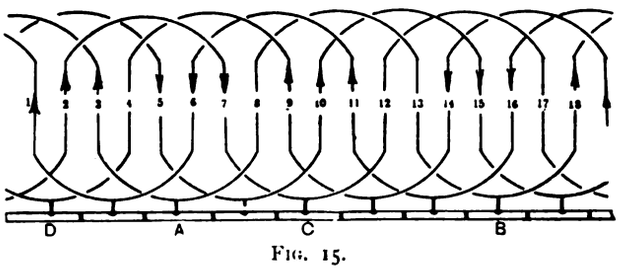

FIG. 15.

In Fig. 15 the armature of Fig. 14 has been treated in this way. But there is also a *second* development which may be carried out from this *first* development, and which is extremely useful in determining the proper brush position for any type of drum winding. (While it is very rarely necessary to employ developments for multiple-circuit windings, it should be understood that the same method is quite applicable to them.)

In Fig. 15 the inductors appear *in the order in which they lie upon the armature periphery*, and they are, therefore, numbered consecutively. The end connections are shown top and bottom, those at the bottom being supposed to be connected to the commutator.

In Fig. 16, however, the inductors appear *in the order in which they are connected* (instead of in order of position), and in this way the circuits which exist are clearly shown.

Figs. 14, 15, and 16 are related in this way. All those inductors which lie under a north pole are assumed to have electromotive forces developed in them, marked in Fig. 14 by + and in Figs. 15 and 16 by arrow heads pointing upwards. The inductors under south poles are marked . in Fig. 14, and have arrows pointing downwards in Figs. 15 and 16. Thus a development like Fig. 15, as commonly used in text-books, shows how the inductors are at any instant grouped with reference to the poles and commutator, but does not bring out clearly the circuits. Our new development (Fig. 16) brings out very clearly not only the circuits which exist in the armature, but also the

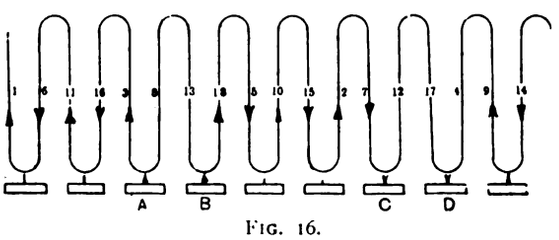

FIG. 16.

necessary places for the brushes, and explains, moreover, the reasons for so placing them.

**Necessary Brush Positions.**

In this diagram the commutator sections are connected to points A, B, C, etc., and obviously we shall need brushes for collection wherever in the winding two series of electromotive forces are in opposition. This is seen to be the case at C and at A. Now, C is the

Digitized by Google

connection of inductors 7 and 12, A is that of conductors 8 and 3. From Fig. 14 it is seen that these two points, A and C, are not connected to the commutator at points 180 deg. apart, but at 90 deg. apart. Between these two brushes, and on either side of them, we have *five inductors in series* (see Fig. 16), and there are only two paths in parallel through the armature, yet the whole winding is effective. Contrast this with Figs. 1 and 2, in which the addition of two extra poles necessitates two extra lines of brushes, and places two more circuits in parallel with the original two, whereas here we have a four-pole machine with *only two circuits in the armature and two lines of brushes.* The effect, then, of going continually forward (instead of alternately backward and forward) has been to restrict the number of armature circuits to two, and the number of necessary rows of brushes also to two.

**More than Two Brushes Possible.**

Now, though it is clear that the brushes at positions A and C are all that are absolutely necessary to enable the full effect of the armature winding to be obtained, yet it is also clear from Fig. 16 that we might have placed the brushes upon B and D instead of upon A and C, and have obtained thereby an equally good result. But though in the second development (Fig. 16) sections B and D appear to lie next to A and C respectively, reference to the other two figures show that this is not the case. In actual position upon the commutator a brush at B falls 180 deg. from the brush at A, and similarly with D and C, so that we have another pair of brushes at 90 deg., which would be just as effective as A and C.

We may, therefore, use either of these pairs, but, on the other hand, there is no reason at all why we should not use both. With such a winding it appears that we may use either one or two negative brushes and a corresponding number of positive brushes upon the commutator; further, that this result is brought about by the system of connection, which, while it joins immediately in series those active inductors lying under the centre of each pole, involves also the immediate series connection of those commutator sections spaced approximately $\frac{360 \text{ deg.}}{2p}$ apart, where $p$ is the number of poles.

**Effect of "Two-Circuit" System of Connection.**

The very essence of two-circuit windings is this fact:

That, no matter what the number of poles, (*a*) half of the active inductors in any single winding are first joined in series (so that the sum of their electromotive forces is taken); (*b*) next, half the inactive inductors are joined to them; (*c*) then the remaining half of the active inductors are taken; and (*d*), last, the remainder of the inactive inductors, when the circuit closes. (See Fig. 16.)

Again, contrast this with a multiple-wound armature in which half the active inductors *under one pair of poles* are joined up, then the inactive inductors corresponding to these, and so on for every pair of poles.

To those studying armature windings, nothing can bring out this point more clearly than a careful consideration of the three figures just given—14, 15, and 16. Many pages of description might be written, but the explanation would have to be varied for each individual instance, and a much better understanding will be arrived at by drawing out diagrams like Fig. 16 for every troublesome case.

The question of whether we use two brushes or four in a case like Fig. 14 depends entirely upon the current to be collected. Thus for a low-voltage large-current machine four brushes would be used, while two are quite common for machines of high voltage, such as tramway motors.

There is another advantage attached to the possibility of using only two brushes with a multipolar machine, especially if these two brushes can be placed at some angle less than 180 deg., for there are many cases (such as motors in awkward positions) where *both* the upper and lower parts of the commutator are not accessible. In such cases, by placing the two necessary brushes (at 90 deg.) upon that side of the commutator which is most readily examined, we get a simple solution of a difficult problem. One frequently meets with this arrangement in tramway and railway motors.

**Effect of Increasing the Number of Poles.**

We have already explained that, with a given bipolar ring winding, if it were possible to add to the magnetic circuit a second pair of poles having the same number of lines per pole as the original pair, another pair of brushes is immediately rendered necessary, and the armature is divided into four instead of two parallel circuits. As a consequence, while the electromotive force of the machine remains the same, the current which may be taken from it (and, therefore, the output also) is doubled.

Similarly, a two-circuit drum armature, suitable to a bipolar field, if duly reconnected and placed in a four-pole field, with the same number of lines per pole, will generate twice the electromotive force that it did in the two-pole field. Since, however, it is still divided into two circuits only, it will carry the same current in both cases; so that, although the output is here doubled, it is by doubling the electromotive force.

The addition, then, of an extra pair of poles (if such a thing were possible) to the multiple-circuit armature would have a result like that of placing two similar machines in parallel; but in the case of a two-circuit armature (duly reconnected) it has a result like that of placing two similar machines in series. For this reason multiple-circuit armatures have been termed *parallel wound*, and two-circuit armatures have been distinguished as *series wound.*

**Value of Two-Circuit Windings.**

If for the armature in Fig. 14 we use all the brushes possible, we have four rows of brushes equally spaced about the commutator, which may be connected together in two pairs, when the commutator and brush gear will have *exactly the appearance of the corresponding multiple-circuit winding, and yet there will be in the armature only two parallel circuits instead of four.* This is the reason why this class of winding is called a two-circuit winding, while the other is termed multiple-circuit. Its great use is to enable us to have a multipolar machine with a large number of commutator segments and plenty of brush surface; while the total number of inductors being divided into only two parallel circuits, yields us a high voltage. Further, it has the advantage that either one pair of brushes, or as many pairs as there are poles, may be used; and since between any pair of brushes at least one inductor under every pole is connected, differences in the air-gap under different pairs of poles do not cause local currents, as is the case with multiple-circuit windings. This is an extremely important point, for, no matter how true an armature may be in its field when new, wear of the

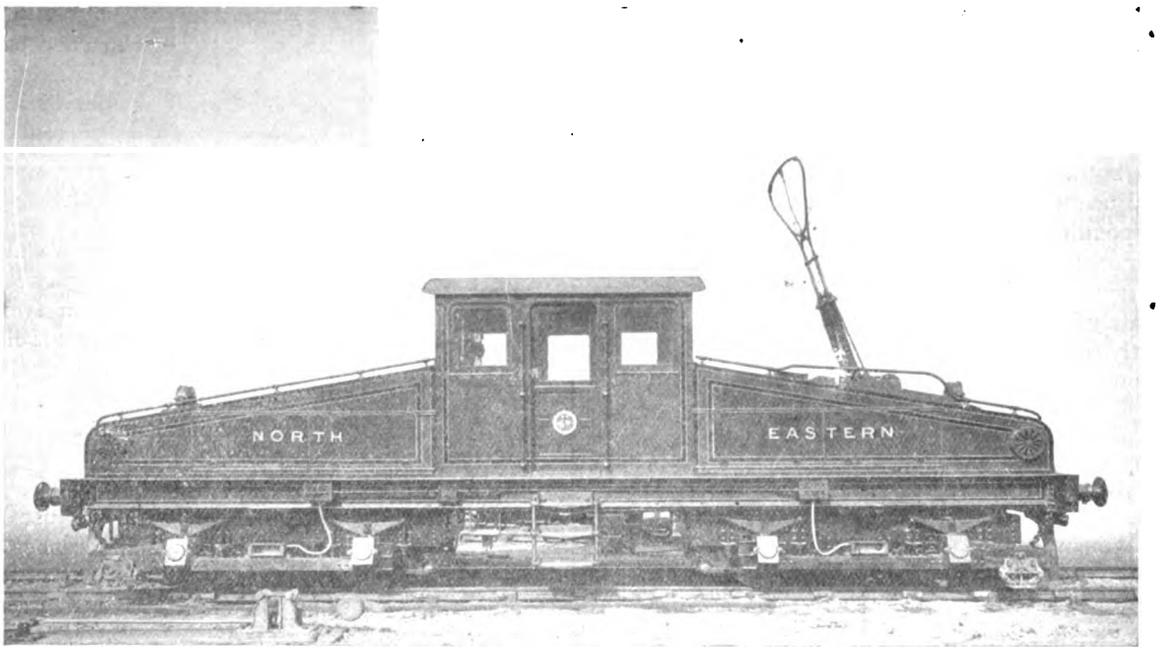
Digitized by Google

bearings is certain to decentralise it sooner or later. Now, looking carefully at any of the multiple-circuit armatures, such as Fig. 1, for instance, if the armature happens to be nearest to the lower north pole the circuit lying between $G_3$ and $G_4$ will have an electromotive force developed in it greater than that in any of the circuits which are in parallel with it. Thus there will be a tendency for a small current to flow through the armature windings alone (independently of the brushes), due to this unbalanced electromotive force. This parasitic current may rise to a large value: in all machines, in order to keep the efficiency high, the armature resistance is kept as low as possible, so that a small unbalanced electromotive force might be responsible for a fairly large current. Obviously also two-circuit windings will have an advantage in cases where large terminal electromotive force is required at a low speed—a case frequently met with in modern practice.

*(To be continued.)*

## THE NORTH-EASTERN RAILWAY COMPANY'S ELECTRIC GOODS LOCOMOTIVE.

As is well known, the North-Eastern Railway Company some few months ago completed the electrification of about



37 miles of their system, on the north bank of the River Tyne, in the immediate neighbourhood of Newcastle-on-Tyne. The whole of the regular ordinary passenger traffic over these sections of railway has for some time past been operated by electrical power, but the goods traffic has, as previously, been dealt with by the ordinary steam locomotives. Now electric traction is invading the goods section of the traffic. The branch line to connect with the Newcastle "Quayside" runs underground for a considerable distance. On account of difficulties in the ventilation of the tunnel the working of this section has been hampered, and hence it is here that electric traction for goods train haulage is first to be employed. For this purpose two very heavy electric locomotives have been obtained.

These locomotives—one of which is depicted in the accompanying illustration—are not only the first of their type, but are the largest electric locomotives ever built in the United Kingdom. They were constructed by the Brush Electrical Engineering Company, of Loughborough, whilst the electrical apparatus—including the Sprague-Thomson-Houston multiple-unit equipment—was supplied by the British Thomson-Houston Company, Limited, of Rugby and London. The locomotive illustrated herewith is of the double-bogie type with central cab and sloping ends, and weighs in running order 50 tons (2,240lb.). The motors are the G.E. 55 type with two-turn armatures and 3·28 gear ratio, one being mounted on each of the four axles. The control adopted is the Sprague-Thomson-Houston multiple-unit system, and is similar to that used for the passenger service. The following are the leading dimensions of the locomotives: gauge, 4ft. 8½in.; length over central cab, 9ft. 0¼in.; length over headstocks, 35ft.; length over buffers, 37ft. 11in.; pivotal centres of trucks, 20ft. 6in.; wheel base of each truck, 6ft. 6in.; width over cab, 7ft. 6¼in.; width over side soles, 7ft. 10⅝in.; width over all, 8ft. 8in.; height from rail to top of cab, 11ft. 9in.; height from rails to top of floor, 4ft. 3¾in.; diameter of wheels, 3ft.; diameter of axles at centre, 6in.; diameter of axles at wheel seats, 7 28in.; diameter of axles at journals, 6in.; length of journals, 10in.

The trucks are of the steel-plate frame type, in accordance with English railway practice, strengthened with steel angles and gussets, with swinging bolster built up with steel sections and steel castings. The bolster is supported on two nests of coil springs of circular section, and is provided with cast-steel wearing plates, cast-steel centre and side bearing plates. The side frames are supported on the axle boxes by laminated springs of heavy design. The axle boxes are of cast steel, machined to work in the horn plates, which are also of steel and machined, being riveted to the side frames, which are cut out to receive them. The axle boxes are provided with wings to take the shoe beams, and are fitted with heavy brasses babbited, ample provision being made for lubrication and the exclusion of dust. The brake gear is of specially heavy design, as it has to play an important part in the work which the locomotive has to regularly operate, the Quayside branch being on an exceptionally heavy gradient. Blocks are fitted to each side of each wheel, and all of the gear is heavy enough to stand operation by air pressure. The wheels are of the cast-steel disc type, balanced and fitted with rolled-steel tyres 5½in. wide by 2½in. deep on tread, held in place by retaining rings and also by eight set screws. The motors are carried on the transoms by means of cast-steel brackets in which the nose of the motor rests, being held there by a forged strap. The shoe beams are of oak, and bolted to the axle boxes, the shoes being hung outside the wheel base. All holes are drilled, edges of plates planed, and rivets hand riveted. The underframe is constructed of steel sections and ballasted with cast-iron blocks to bring up the weight desired. Each side

Digitized by Google

sole is formed by a girder 12in. by 6in. by 54lb. and of I section. There are two centre longitudinals each 8in. by 3½in. by ⅝in. of channel section, these four longitudinals being connected at their ends by headstocks 15in. by 4in. by ½in. of channel section, whilst to the front of these is bolted oak headstocks, 15¾in. by 8in. The whole frame is firmly riveted together with steel angles and gussets, all the holes being drilled and the edges of plates machined. The underframe bolster is formed by two girders, each 6in. by 5in. by ½in., of I section, held together on the top by a plate 3ft. wide and ⅜in. thick, whilst on the lower side is a plate 17in. wide by ¼in. thick. Between the bolsters, evenly spaced, there are five cross girders, each 8in. by 3½in. by ⅝in. of channel section, backed with a plate 15in. wide by ½in. thick. On the top of the frame is a floor of fireproof wood 1⅞in. thick, fixed transversely with a top or lining floor, laid longitudinally. The draw gear, side couplings, and buffers are of the standard English pattern. The centre cab is constructed of ⅛in. steel plate and angles, and is separate to the sloping ends, which are also constructed in a similar manner, all three portions being bolted to the underframe. The cab is provided with two side windows on each side, the one at the driving corner being arranged to lower. A sliding door is fitted on each side, of ash, glazed at the top and panelled at the bottom, bearing on the outside the arms of the North-Eastern Railway Company, in transfer. The doorways are 2ft. 4in. wide and 6ft. in the clear. At the ends of the cab are two windows arranged to slide transversely. Arrangements have been made for driving the locomotive from each end of the cab, and it is, therefore, fitted complete in duplicate, with master controller, air-brake, sand and whistle valves. In the centre of the cab is fitted a cast-iron column to carry the hand-brake gear, on each side being a panel for the control and pump circuit accessories, with a main panel at one end for main and control switches, etc. Air-gauges and ammeters are also fixed in each driving position. Under the sloping ends are fixed the contactors, reversers, and rheostats, the apparatus for each two-motor equipment being fitted on its own end of the cab, the four-motor equipment being thus split up into two equipments, as far as possible, as regards location. The contactors are supported from an angle-iron framing built on the floor of the cab, the reversers and resistances being bolted to the floor, but raised above it so that the cable runways may run underneath them. The air-brake is of the quick-acting pattern, air being supplied by a B.T.H. electrically-driven compressor of the C.P. 14 type, which is hung underneath the frame. This compressor is able to compress against a pressure of 90lb. per square inch, with a cylinder displacement of 20 cubic feet per minute. The air reservoirs are fixed in the ends of the sloping cabs, as also are the sand hoppers, the sand being carried by flexible tubes to the fixed pipes on the trucks, the air-operating pipes being connected to the same at the base of the hoppers. The lighting in the cab is performed by shaded lamps fixed in each driving corner with three lights in each of the sloping ends.

There is a headlight on each end of the locomotive. All lamps are of 32 c.p., and arranged for working six in series on a 600-volt circuit. Two portable lights are also provided. As these electric locomotives operate over sections of the North-Eastern Railway which are equipped with the overhead line and the third rail, a sliding bow trolley, of special design, has been provided, which automatically reverses itself, according to the direction of travel of the locomotive, whilst the bow trolley, when not in use, can be reversed and lowered from the cab by the operation of a hand-wheel actuating a worm and wheel device. All cables are asbestos covered, and are run either in wood troughing lined with uralite or in steel tubing. Besides being fitted with the nine-wire coupler at each end for the control circuit, 'bus or main line and pump line couplers have also been provided, so that two of these locomotives can be coupled together, if necessary, and operated by one man, for dealing with heavier loads. Each of these locomotives, when operating on a 600-volt circuit, is capable of handling a 300-ton (2,240lb.) train on the level at a speed of 14 miles per hour, and of starting with a train of 150 tons (2,240lb.) on a grade of 1 in 27 under all conditions of weather, running up this grade at a speed of nine to ten miles per hour. In the course of some recent official trials with the first of these locomotives, we understand that the speeds and haulage records named above were easily exceeded. The working of the electric locomotives on the North-Eastern Railway will doubtless be watched with no little interest, as, should expectations be realised, the principle of utilising electric locomotives for hauling goods wagons on purely "goods" lines or in marshalling yards will be extended to other British railways.

## ELECTRICITY SUPPLY IN PARIS.

The Technical Commission who have reported on the future regulations for the supply for Paris give in their report some interesting calculations, both as to the cost of electrical energy under the proposed new conditions and also as to the best system of charging. The following gives in an abridged form the two sections of the Commission's report dealing with the subjects.

*Prime Cost of Electrical Energy.*—As there does not exist at the present time an enterprise comparable in size and arrangement with that advised for Paris, the estimates given below are based on extrapolation from results acquired elsewhere. This fact has made the commission very careful to guard against a too favourable view of the economical advantages from the concentration of the producing plant into a few large works. The following estimates of charges are, however, believed to be correct within close limits. It must be remembered that the figures given will not be obtained at once, but only after the stations have been at work some years. The cost of the first installations are calculated to be as follows:

| | |
|---|---|
| Generating stations for a useful maximum output of 70,000 kw. at £20 per kilowatt | £14,000,000 |
| Sub-stations with materials and buildings at £6 per kilowatt | 4,200,000 |
| Mains for high and low tension, not including services or meters, £28 per kilowatt | 19,600,000 |
| Total | 37,600,000 |
| Contingencies | 2,400,000 |
| | £40,000,000 |

This gives in round figures £56 per kilowatt of power obtainable from generating stations. This charge is very considerably below what the present installations in the city of Paris have cost. But it is higher than the mean cost of the stations recently provided.

*Cost of Working.*—The cost of working is composed, first, of the charges for the repayment of capital and the renewal of materials; secondly, of the direct cost of production and distribution of the electrical energy and the administration of the undertaking. The capital of £40,000,000 requires for interest and sinking fund over 35 years an annual charge of 6 per cent. The depreciation funds for the renewal of plant are calculated on the following basis: the renewal of the boilers in 10 years, the renewal of the machines in 15 years, the renewal of the buildings and mains in 35 years. The charge for depreciation corresponding to these lives of the respective parts gives a mean charge of 3·35 per cent. If this charge is calculated on the £37,600,000, the total fixed expenses amount to about £367,000.

The direct costs of working can be fairly calculated from statistics from other stations, which show that the works cost may be divided nearly as follows: 40 per cent. for fuel, 35 per cent. for wages, and 25 per cent. for other charges. It is also known that the cost of supervision and the general commercial expenses represent about 25 per cent. of the works cost. The Commission assume that coal at 16s. per ton will be available, and that about 3·3lb. will be required per unit generated, or 5lb. per unit sold. This gives an efficiency of distribution of 66 per cent.; adding 10 per cent. for oil and stores, the fuel charge per unit works out at 0·476d. per unit. Allowing, then, for wages and other expenses in the above proportion a total works cost of 1·187d. is obtained, or a total cost of 1·48d. per unit.

Digitized by Google

In order to deduce from this prime cost of energy sold, it is necessary to take into account the power factor of the load. This idea of power factor is of great importance in the economical problems connected with central stations. It results from a comparison of the real output from the works with that which they would be able to produce if worked continuously. It is the quotient of the annual kilowatt-hours sold by the kilowatts of power available in the stations. This gives a certain number of hours. This power factor depends on the use made of the current, whether for light or power, and also on the business of the consumer. Its mean value is fairly well known to be as follows:

| | | |
|---|---|---|
| Lighting for private houses and offices | 200 to 500 | hours. |
| ,, shops | 500 to 750 | ,, |
| ,, cafés and theatres | 750 to 1,500 | ,, |
| ,, public lighting | 1,800 to 3,700 | ,, |
| ,, motive power | 1,000 to 3,000 | ,, |

The mean very generally obtained in enterprises not unlike those of Paris is about 750 hours. It can be improved by the extension of power consumers, but it seemed reasonable to the commission to calculate the net price on this basis. The higher use of 1,000 hours per year obtained in some present supply systems in Paris is explained by the fact that they are approaching the end of their concession. With a power factor equivalent to 750 hours' use per year the following figures of income and expenses can be obtained; the units sold will equal 70,000 kw. × 750 hours = 52,500,000 units. The cost of supply will be as follows:

| | |
|---|---|
| Interest and sinking fund | £3,400,000 |
| Renewal of plant | 1,265,000 |
| Cost of current at 1·48d. per unit | 3,250,000 |
| | £6,915,000 |

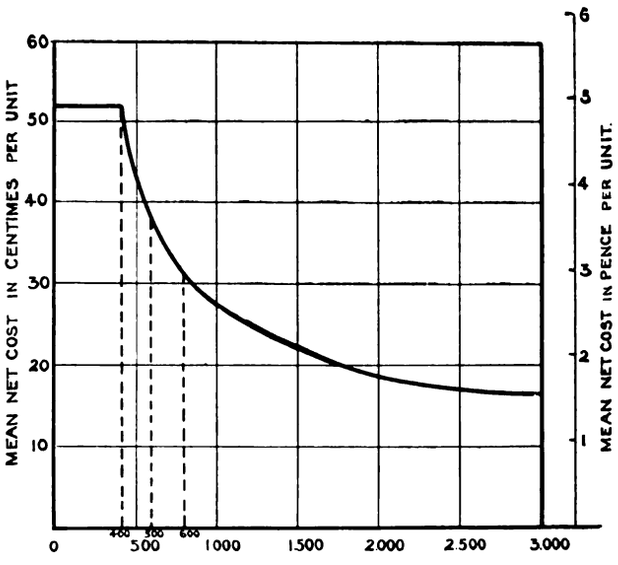
The net cost obtained by dividing this sum by the number of units works out at 3·16d. per unit. It should be remembered that this estimated price corresponds to a definite stage in the development of an undertaking which is bound to be progressive.

*Scale of Charges.*—In studying the system of charging the commission had naturally in view the net cost of production. The total cost of 1·48d. per unit sold given above corresponds to a mean of 750 hours' use of the maximum by the consumers taken as a whole. This mean ought to be considered as resulting from the different means under the various heads indicated above. It seems well determined to-day that a uniform price for all consumers is not applicable to the sale of electrical energy. In its place one looks for a scale of charges which takes account of the quality of the consumers. Instead of a uniform price, one seeks to discover a uniform sliding scale applicable to all. The commission think they have obtained such a scale by the following reasoning. When one looks for the true grounds on which a consumer should ask for a rebate on a fixed price, one quickly sees that this must solely depend on the power factor of his installation—that is to say, the number of hours during which he makes use of the electrical energy. Thus, if one considers in detail the expenses of all kinds which go to make up the net cost, one sees that these expenses are of two kinds. The first includes the fixed charges depending only on the plant installed, and in consequence on the maximum demand at any time; the second, on the contrary, are proportional to the total annual output, and in consequence to the power factor of the installation. This can be represented in a simple mathematical formula, $A - B\,x$, where A represents the fixed charges independent of the units sold, $x$ and $B\,x$ represent the part of the expenses proportional to the output.

It seems, then, reasonable to look for a formula of the same type for the scale of charges which the consumer should pay. First, a sum fixed proportional to that part of the fixed cost incurred on his behalf, say A'; and, secondly, the cost of his consumption of energy at a uniform rate, B'. This idea has already been proposed for the municipal station at Halles, but the determination of the charge A' was not then made on a practical basis. This sum, called the connection charge, is calculated on the total power of all the apparatus installed. Nothing is more variable than this power, because, for instance, it is sufficient to vary the candle-power of the incandescent lamps to change it in the ratio of 1 to 4. In order to ascertain its value and variations, it becomes necessary to demand from the consumer a statement of all modifications made in the number and candle-power of the lamps fixed. It is still necessary to verify his statements by a system of control which becomes like an inquisition; in fact, these declarations are neither made nor checked, and the real base for the charge A' absolutely vanishes.

It is, however, easy to transform the conditions by making the base of calculation the electricity meter. This is designed to record a certain nominal power which corresponds to the maximum simultaneous load on the installation. This power is fixed by the meter itself. It is invariable, and has all the qualities required to serve as the basis of the charge A'. In the case where the maximum at any time is not carried beyond the sum of the power installed, the size of the meter represents better than it that part of the fixed charges which should be borne by the consumer. Again, the choice of the size of the meter as the basis of the fixed charge dispenses with all declarations or domiciliary visits, in case modifications are carried out on the installation.

The commission add that one could equally well take as the base of this charge the indications of a maximum demand indicator, such as Wright's. The result would be equally well obtained, but if it is possible to avoid additional apparatus it is preferable to do so. The charge A' ought then to be fixed on the nominal power of the meter. The report goes on to show that any fixed charge which is independent of service rendered is objectionable to the public, hence advises than discharged A' should be replaced by higher charge for the first, N, number of hours' use of the normal power of the meter. Thus the first units supplied will be paid for at one rate until a quantity equivalent to 400 hours' use of the normal power of the meter has been reached, after that the charge will be lower. Calculations are given to determine what these rates per unit should be, with the result that the commission advise a charge of practically 5d. per unit for the first 400 hours' use of the normal power of the meter, and 1·05d. for all energy consumed over and above this.



Net Cost of Electrical Energy in terms of the Duration of Load.

The curve given herewith reproduces this scale graphically, and the commission also give formulæ for calculating the charge when the number of hours' use per year is known Thus, for 1,000 hours per year, the charge would be 2 64d. per unit; for 2,000 hours, 1 834d.; for 3,000, 1·58d.

[N.B.—This proposed system of charging is distinctly novel, but we fail to see that it really accomplishes the purpose for which it was devised. The fault lies in the assumption that the nominal power of the electricity meter represents fairly the maximum demand of any consumer. Thus, for instance, all those small consumers who have meters of 10 amperes capacity would have to pay at 5d. per

Digitized by Google

unit for all they consume until the units are equivalent to a load of 10 amperes at 110 volts for 400 hours. Some of these consumers may never need to take over five amperes, and hence would have to do without rebate until after 800 hours' use. In the alternative, a consumer requiring at first 10 amperes and extending his lighting without notice will get a reduction to a lower rate of 1·05d. per unit much before the 400 hours have expired. In fact, the Technical Commission have adopted the Wright maximum demand system of charging, and have then spoilt it by trying to do without a maximum demand indicator.—ED., *E. E.*].

## THE VALUE OF OVERHEAD MAINS FOR ELECTRIC DISTRIBUTION IN THE UNITED KINGDOM.

BY G. L. ADDENBROOKE.

The above paper, read before the Institution of Electrical Engineers in London, deals with the general advantages of overhead mains rather than with any details in their construction. For this purpose the author gives the following two tables, showing approximately the cost of overhead conductors and underground mains employed under similar conditions.

OVERHEAD MAINS.—THREE-PHASE CABLES. ON THE BASIS OF 1 PER CENT. LOSS PER MILE.

| Particulars of the conductors. | | | Carrying capacity in kilowatts at the following voltages. | | | | Capital cost of line complete per mile, allowing 45 poles per mile at the following voltages. | | | | Capital cost of line complete per kilowatt conveyed per mile at the following voltages. | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Size of cables. | Section of cables in square inches. | Weight per mile in lbs. | 6,000 | 8,000 | 10,000 | 12,000 | 6,000 | 8,000 | 10,000 | 12,000 | 6,000 | 8,000 | 10,000 | 12,000 |
| | | | | | | | £ | £ | £ | £ | s. d. | s. d. | s. d. | s. d. |
| 3 7/18 | 3 ·01292 | 3× 266 | 81 | 152 | 225 | 323 | 211 | 230 | 245 | 260 | 52 0 | 30 0 | 22 0 | 16 0 |
| 3 7/16 | 3 ·02299 | 3× 468 | 143 | 254 | 400 | 545 | 259 | 275 | 290 | 305 | 36 3 | 21 8 | 14 6 | 11 3 |
| 3 7/14 | 3 ·03588 | 3× 730 | 222 | 394 | 615 | 887 | 301 | 316 | 332 | 347 | 27 0 | 16 0 | 10 9 | 7 10 |
| 3 19/16 | 3 ·06247 | 3×1,270 | 382 | 680 | 1,060 | 1,526 | 402 | 418 | 433 | 448 | 21 0 | 12 4 | 8 2 | 5 10 |

UNDERGROUND MAINS.—THREE-PHASE CABLES. ON THE BASIS OF 1 PER CENT. LOSS PER MILE.

| Particulars of the conductors | | | Carrying capacity in kilowatts at the following voltages. | | | | Cost of main complete laid and jointed at the following voltages. | | | | Cost of line complete per kilowatt conveyed per mile at the following voltages. | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Size of cables. | Section of cables in square inches. | Weight per mile in lbs. | 6,000 | 8,000 | 10,000 | 12,000 | 6,000 | 8,000 | 10,000 | 12,000 | 6 000 | 8,000 | 10,000 | 12,000 |
| | | | | | | | £ | £ | £ | £ | s. d. | s. d. | s. d. | s. d. |
| 3 7/18 | 3 ·01292 | 3× 266 | 81 | 152 | 225 | 323 | 490 | 540 | 678 | 800 | 120 0 | 71 0 | 60 0 | 49 6 |
| 3 7/16 | 3 ·02299 | 3× 468 | 143 | 254 | 400 | 545 | 520 | 635 | 725 | 870 | 73 0 | 50 0 | 36 0 | 32 0 |
| 3 7/14 | 3 ·03588 | 3× 730 | 222 | 394 | 615 | 887 | 545 | 660 | 772 | 950 | 49 0 | 34 0 | 25 0 | 21 0 |
| 3 19/16 | 3 ·06247 | 3×1,270 | 382 | 680 | 1,060 | 1,526 | 760 | 858 | 957 | 1,050 | 40 0 | 25 0 | 18 0 | 13 9 |

Commenting on these tables, the author states that "an inspection will show that at 6,000 volts between conductors on a three-phase system the cost of the overhead conductors is about half that for underground cables. If the voltage is increased, the cost of the overhead line only rises slightly while the cost of the cables increases more rapidly, so that at 10,000 volts the cost of underground is nearly three times the cost of overhead transmission. In the costs for the overhead transmission a fair sum is included for extra poles and networks when crossing roads or places to which the public have access. In these tables the costs of overhead conductors have been calculated on the basis of a single set of conductors of the sizes mentioned on a pole, but when more power is wanted a second set of conductors can usually be added at the cost for copper, insulators, arms, and erection only, whereas to lay a second cable will cost practically as large a sum as the first. Herein lies one of the great advantages of overhead distribution: the current can be taken to a works and a small-sized set of conductors put up to commence with at half the capital outlay required for laying a cable of similar section. If the use of electric energy should afterwards be discontinued for any reason, the poles and wires can be recovered and are still worth a great part of the original value, as they can be used elsewhere. If, as is probable, the use of current is extended, another set of larger conductors can easily and cheaply be erected. With a cable, if an underground main is discontinued it is worth nothing to take up. To lay a full section cable in the first instance means locking up a great deal of capital unremuneratively, possibly for some years; on the other hand, to lay a small cable first and a second larger one later is very expensive. In the first case—viz, with overhead conductors—the capital required will only be half that required in the second, and, moreover, a good proportion of it will remain in a liquid form. Thus by employing overhead conductors a power company is sinking a much smaller amount of capital in extending its mains widely during its early stages. Besides the lower cost per mile of the distributing system with overhead mains, and which in many cases would make the difference whether a supply can be given profitably or not, it is important to observe also that if it will pay to carry the current a certain distance by underground mains, it will pay to carry the current nearly twice as far with overhead conductors, which means that a power station can economically supply current over about three times the area which would be possible with underground transmission at 6,000 volts, and if the pressure is increased the relative areas shows a still greater difference. For this reason not only has a power station with overhead transmission a much larger area from which it can pick up customers and thus acquire a load quickly, but it will later on have a larger area to draw customers from, so that the advantages of additional size and concentration are also secured in a greater degree."

Elsewhere in the paper the author lays stress on this absence of danger from the use of overhead wires, as proved by foreign experience, and on the reliability of supply when the wires are properly erected and looked after. He claims that with overhead wires for transmission and distribution of energy the use of electricity could be much more quickly extended in this country to small centres of population.

Digitized by Google

Dealing with the use of such mains in this country, Mr. Addenbrooke states that the Board of Trade have passed a series of routes designed by him, but that the Board still appear to have objections to high-pressure transmissions being erected along the sides of roads. Consequently, as things stand at present, wayleaves usually have to be obtained for carrying the mains across the neighbouring fields. In many districts there will not be much difficulty in obtaining such wayleaves, but the author would prefer to secure in this country a set of laws and regulations such as have been made in several foreign countries giving undertakers the power to obtain such wayleaves by a form of compulsory arbitration when it can be shown that the project is of public utility. The Swiss and Italian laws and regulations on this subject are given in the appendix to this valuable paper, which we regret we have not been able to reproduce in full.

---

DISCUSSION.

**Mr. John Gavey** thought the paper had come at a very appropriate time, now that objections to overhead telegraph wires were being raised by local authorities, who, he hoped, would take a more liberal view in future. He would like to know whether the variation in the author's estimate of the cost of erection was to provide for varying voltages or for additional precautions at cross roads, and whether the cost of wayleaves was included in the estimates. In the latter connection there was the question of diversion of route through difference with landowners. Allowance was only made for running three wires on main-line poles. Would these suffice to maintain a continuous service year in and year out? He quoted the case of the Milan high-tension system, where 18 wires are provided, half on each side of the pole, so that one set could be switched off when repairs were needed. It would be as well to keep this phase of the subject in mind, since faults such as breakage of insulators would always occur. He did not think that extra wires in underground mains would be as expensive as the author stated, as spare ducts could be laid at comparatively small cost. Most highways had telegraph wires, so it would be necessary to guard against electrostatic and electromagnetic disturbances, which could be largely obviated by the symmetrical arrangement of the wires. One advantage of private wayleaves was that a route could be selected with as few trees as possible.

**Mr. R. S. Portheim** mentioned that his firm were intimately associated with the scheme of the North Wales Power Company, the practicability of which depended largely on the cost of transmission. The cost of equipping the company's 60-mile overhead line was under £40,000; with underground cables it would have been about £150,000, rendering the scheme commercially impracticable. The Board of Trade had adopted a very reasonable attitude in regard to carrying the wires along the highways, and the Welsh farmers had also proved exceedingly amenable.

**Mr. C. P. Sparkes** considered it was the local authorities, not the Board of Trade, who had been to blame for obstructing overhead progress. Regarding the route to be followed, the best method was to work along the main roads, avoiding, if possible, routes selected by the Post Office.

**Mr. H. M. Kensit** stated that his company's experience in acquiring wayleaves had not been a very happy one, some landowners declining to negotiate at all where the company had no compulsory powers.

**Mr. A. Blumenthal** related the experience of his company in laying a 500-volt continuous-current line which crossed a telephone line. They offered to instal the ordinary protective fuses, but the telephone people insisted upon the ordinary wires being replaced by rubber-insulated wires, the rubber of which soon wore off. He had found the authorities abroad much more rational, small protective devices sufficing to meet their regulations. Managers of Continental overhead systems had told him that they had never known of a breakage of the wire resulting in loss of life. He recommended lightning arresters of the horn type with magnetic blow-outs. Regarding stone throwing at insulators, his company had found resort to the schoolmaster or parson better than the police.

**Mr. Pooley** confessed that he at first felt apprehensive for the cablemakers, but on reflection he considered overhead wires would rather assist them, as these would be commercially practicable where underground cables were not, and underground cables, he thought, would still be necessary for distribution in large towns. He considered the author had underestimated the cost of wayleaves. Danger from overhead circuits could easily be prevented by simple devices, and faults were scarcely more likely to occur overhead than underground. When they did occur they were much easier to locate. He thought it out of the question to paint creosoted poles, as it would render them an eyesore. Pitch pine would be the best wooden poles. He hoped that when the author spoke of a cheaper system of wiring, he had in his mind a cheaper method, and not a further cut in rates, which were already low enough.

**Mr. L. Gaster** expressed curiosity as to the relative advantages of copper and aluminium for overhead wires.

**Mr. Addenbrooke,** replying, stated that, in regard to Mr. Gavey's question, the variation in cost of erection was due to the extra insulators and larger poles used in some cases. The tables given in the paper had been compiled on a three-wire basis for the sake of convenience. In America three wires had been found sufficient except for very long distances, and when more were erected the cost amounted to little more than the price of the material. In regard to running lines near Post Office wires, a great deal depended on the question of crossing, but from a pamphlet of the American Institute of Electrical Engineers he saw it was pretty generally agreed that it was quite possible to go near your neighbours without much disturbance. In some cases telephone wires were carried on the same poles as the lines transmitting power. Regarding the attitude of the Board of Trade, he explained that this had been modified as the result, he believed, of representations made by himself. At present, however, the Board would not countenance overhead lines on main roads. He had been told on the Continent that serious accidents were unknown. Regarding wayleaves, he had generally found things work smoothly, except when solicitors entered into the case—and the clerks to local authorities were usually solicitors. He did not think the cablemakers need be alarmed; there would be plenty of work for them, and they could also supply the overhead mains. He mentioned that in America and on the Continent they were reducing the number of poles by using stranded hard-drawn copper wire. Aluminium was not suitable for long spans. He concluded with an appeal for wider statutory powers for undertakers of overhead systems.

## APPLICATION OF ELECTRICITY TO MINES.*

BY A. C. ANDERSON, STUDENT.

(*Concluded from page 305.*)

### MOTORS.

When enquiring for motors for use in mines, managers should invariably specify as clearly as possible the exact nature of the load, the maximum temperature rise permissible, and any peculiar conditions under which the machine may have to work. The question of temperature is a difficult one owing to the very different conditions prevailing in different parts of the same mine; but the engineer should know where his motors are going, and can specify accordingly. Of course, in the case of portable gear, which may be used anywhere, the worst possible case must be provided for, and an adequate factor of safety allowed. As far as possible, motors for use underground should be enclosed in motor-rooms. This is manifestly impossible in the case of coal-cutters, drills, and locomotives, where, at any rate in dangerous mines (locomotives being eliminated), the case of the motor should be its own room, so to speak. With regard to continuous-current gastight motors, it is held that inspection covers must be provided, and that this is like giving the miner an unlocked safety lamp. Why not give the miner a locked motor and make its inspection a part of the general system? Mr. Henry Hall thinks that a motor cannot be kept properly cool if it is totally enclosed; this is obviously wrong.

It is merely a question of rating. The induction motor has a slight pull here, as, though the modern continuous-current motor is practically sparkless, the frequent intense vibration in coal cutting and drilling must eventually cause some trouble with the latter type. Totally-enclosed motors for certain conditions are absolutely necessary, and, unfortunately, there seems some foundation for the assertion that anything quite enclosed is liable to neglect. They should be most carefully designed not to overheat, and should be rated carefully in accordance with the nature of the load, a special margin being allowed for coal cutters and drills, which meet with the roughest treatment. The machine is not always switched off at once when the cutter jambs. All motors should certainly be guarded from circumstances such as these by means of suitable cut-outs, preferably situated in a properly protected box, obviating serious burn-outs in the windings, which have proved so far a very frequent source of accident. Armature belts are best away in motors for stringent conditions, the conductors being held in their slots by wedges. The shunt "kick" of machines should always be taken up in the controlling gear to prevent the possibility of sparking at contacts.

Mr. Garforth, of Normanton, who has made some very interesting experiments on the risks of explosion with motors, found that gas can get through an armature shaft bearing, but not in sufficient quantity to cause an explosion internally. He also found that the internal explosion incidental to the admission of gas to the interior of a gastight case did not fire the gas outside the case. Mr. W. C. Mountain performed some experiments with motors at the request of the committee dealing with the use of electricity

* Paper read before the Birmingham Local Section of the Institution of Electrical Engineers.

Digitized by Google

in mines. He got no explosion with a mixture of gas and air when the proportion of the former to the latter was as 1 is to 15. He was further able to increase this to 1 to 10, and even to 1 to 8, without the occurrence of any explosion. When he adjusted the brushes, with the set purpose of making the machine spark, an explosion took place when the proportion of gas to air was 1 to 10.

APPLICATIONS

(*a*) *Pumping.*—Electricity is most commonly applied in mines to pumping, a use to which it is eminently suited, especially in connection with centrifugal pumps at constant load. In the Monterrad pits of the Roche-la-Moliers and Firminy Mining Company, the workings being gassy, the motor (three-phase) has a closed circuit winding without slip-rings, and no switches are placed underground. To start the plant the generator, an inductor alternator, is fully excited, and then run up slowly, taking the pump gradually to full speed with it. Near Dortmund there are some 665-h.p. pumping sets taking current at 2,500 volts, where two methods of starting up are provided. The motor may be connected to the one of the two dynamos which is at rest and attain full speed with it. This is the simplest way. No collector rings are required on the motor, but it is first necessary to stop a dynamo. Two separate three-phase circuits must be allowed for at the switchboard—one for ordinary light and power, and one for pump motors. It was found desirable to be able to start the motor direct, and an oil-cooled starting box was put in, by which means resistance was introduced into the rotor circuit. At Horcajo, in connection with electrically-driven pumps, Heerwagen's short-circuited rotor answers very well. The stator bears nine coils, each of 42 turns; the three coils of each phase are in series, but the three phases are connected in mesh fashion. The rotor carries 360 flat copper rods, arranged in two layers, in 180 holes, and is so connected that six rods are in series, thus giving 60 circuits. The centrifugal pumps can start with zero torque, gradually increasing, and can be brought to full speed when full of water in 100 seconds. The motors are started by means of an auto-transformer giving 400 volts, the primary pressure being 1,000 volts. When the auto-transformer is switched in the first motor is joined to the starting bars, and takes at first from 200 to 240 amperes, but rapidly reaches synchronism. This point is marked by a sudden decrease in current strength, when the connections are changed over to main 'bus bars, so that motor continues to run at full pressure. The second motor is then started in the same way, and the auto-starter finally cut out.

(*b*) *Winding and Haulage.*—Electricity has not as yet come much into vogue for winding in this country, though electrically-driven haulage gears have made much headway. Of the many ingenious devices designed to meet the difficult conditions of a winding plant, the Ilgner Siemens and Halske is the best known. Here a multiphase current drives a motor direct coupled to the armature of a continuous-current dynamo, the connecting shaft carrying a heavy flywheel. The direct current from the dynamo drives the motor coupled direct to the winding drum. The energy thus stored in the flywheel is available for starting the cage. Speed variation is possible by varying the field strength of the dynamos (which should be separately excited) driving the winding motor. Under ordinary working conditions an efficiency of 60 per cent. may be looked for. This figure represents the ratio of the power available for raising the load in the shaft to that at the terminals of the motor-generator. For winding where electric driving has superseded steam the cost of working has been much reduced, the steam consumption per horse-power hour coming down to 24lb. to 26lb. on mineral raised. The constant turning moment of the electrical motor is more favourable to the life of ropes than the varying torque of steam-engines. "Dancing" of the rope is done away with, and drums can be much lighter than with steam winding plant. The Koepe pulley system of winding is specially suitable for electricity owing to the high speed. The Koepe pulley consists of a grooved pulley of large diameter mounted on a shaft coupled to the winding motor. The winding rope passes round this pulley and over the pit-head gear outside the winding shed, and is thence attached to the cages. It forms thus an endless system. The arc of contact of the rope on the Koepe pulley is so chosen that the maximum loads occurring are lifted by the friction alone between the rope and the pulley, an ample safety factor being allowed for. It has been found possible, working this system electrically, to reduce the weight of the winding pulley to about one-half the weight of the drums usually required for steam winding plant. It is best to use liquid rheostats in connection with haulage gears. Batteries are very good for levelling load on winding machinery. The braking of haulage plants is frequently accomplished by making the motor run as generators returning current to the line, but this is always backed up by hand and automatic devices. There was exhibited at Dusseldorf a winding engine where the varying load was taken up by a storage battery, and to this an Ilgner drive has now been added. About 1,000 tons are raised per day. The Ilgner drive consists of a 300-h.p. motor on a 500-volt direct-current circuit driving a steel flywheel 4m. diameter, weight about 40 tons, and a direct-current dynamo at speeds up to 350 revolutions per minute. The motor, flywheel, and dynamo are all arranged on the same shaft. The dynamo sends current up to 2,000 amperes into winding motors, whose terminal voltage increases to 500 volts. The balancing of power is effected by the variation in speed of the flywheel shaft. The plant at the Thiederhall pit, installed by Siemens and Halske, is driven by two continuous-current motors, with an equalising battery for starting and speed regulation.

(*c*) *Coal-Cutters.*—Coal-cutters should be lavishly designed for strength and reliability in working. They should be able to stand at least 30 per cent. overload for short periods, and they must be reversible. It is held by some that an arrangement of two motors in series is good for coal-cutter driving, as each machine has only half the line voltage across its terminals, and not only is the weight better distributed, but there is generally more head room. The starting switch should be enclosed in an airtight case. Provision must be made for carrying 70 yards or so of armoured cable on the motor truck, preferably coiled on a drum. The box containing the main switch and fuses should be placed where work is commenced, and cable should be paid out as the cutter advances, a sufficient length having been provided for the face of coal to be cut during a given shift. In the case of disc machines, for satisfactory working there should be a good floor and roof, and the material in which the cutter works should not be too hard, and as free from ironstone balls as possible. Messrs. Ernest Scott and Mountain have been good enough to give me some figures of a performance of one of their machines of this type at the Smithywood Colliery, near Sheffield. These are set out in the accompanying table, and show what may be done with up to date machinery.

DISC MACHINE.—Working of Coal-Cutter at Smithywood Colliery.

| Date. | Time started. | Time finished. | Min. run. | Depth of undercut. | Thickness of cut. | Material cutting. |
|---|---|---|---|---|---|---|
| | p.m. | p.m. | | ft. in. | in. | |
| Dec. 16. | 10 30 | 10.33 | 3 | 4 6 | 5 | Stones, coal mixed with stone. |
| | 10.34 | 11.34 | 60 | | | |
| | 11.46 | 12 50 | 64 | | | |
| | 1.16 | 1.33 | 17 | | | |
| | 2.20 | 2.23 | 3 | | | |
| | 2.29 | 2.31 | 2 | | | |
| | 2.33 | 3.0 | 27 | | | |
| | 3.7 | 3 33 | 26 | | | |
| | 3.36 | 3 39 | 3 | | | |
| | 3.50 | 4 2 | 12 | | | |
| | 4.26 | 4.56 | 30 | | | |
| | 5 9 | 5 20 | 11 | | | |
| | 5.21 | 5.33 | 12 | | | |
| | | | 270 | 105 yds. cut. | | |

Total hours from first switch on to last, 7 hours 3 minutes; 4½ hours actual cutting; 2 hours 33 minutes changing cutter twice, running rope out three times; average amperes, 37; average volts, 470.

(*d*) *Drilling.*—With regard to rock drills, where electricity is in keen competition with compressed air, it is to be noted that (1) with pneumatic drills there is no deafening noise of the exhaust, no power to draw back the drill when

Digitized by Google

jammed in the borehole, and there are heavy losses in cumbersome piping. Moreover, a severe capital outlay is unavoidable owing to the large power and space required, and the plant when installed is very inefficient. (2) Electric drills are much lighter and more handy than the above, occupying but little room. They are 30 per cent. cheaper in first cost than air-drills, and the medium for transmission of energy is far more flexible and efficient. The Durkee electric drill is driven through a flexible shaft by an independent motor of 1½ h.p. The motion is given by a special crank, which gives a slow return and a quick forward or cutter stroke; the driving collar moves the drill spindle through springs so as to cushion the motor of the drill if the cutter is not striking the rock, and to allow for irregularities in the feed. The drill is rotated by the usual rifled rod and pawl. The machine weighs 230lb. without tripod, and makes 580 strokes per minute. The Marvin percussion drill of solenoid type, requiring a special alternator, needs from 20 kw. to 32 kw. at generator, and delivers 450 to 550 blows per minute. Drills of the Marvin and Van der Pode type, however, have never been a commercial success, as they get hot and require, beside a special generator, cooling arrangements, rendering them liable to get out of order. Mr. Walsh, in the *Engineering and Mining Journal* of New York, discusses electric drills working in the mines of the Consolidated Cariboo Hydraulic Company at Bullian, British Columbia; direct-current portable 1½-h.p. and 2-h.p. motors are used. Three drills averaged 312ft. of holes in 10 hours through solid rock. Cost of current was 9·37s., and lubricants 7½d.; a blacksmith at 16·64s., and a helper at 8·32s. must be added. The total cost of running the drills for 10 hours was about 131s., saving approximately 208s. on hand drilling. The power was generated by steam-engines, so that the results cannot indicate the maximum efficiency obtainable. The consumption of power was considered without reference to wages. The tests were extensive enough to give good average values. An 86in. hole, 2in. diameter, was drilled in 19·08 minutes. Total consumption of power was 940 watt-hours, or 131 per foot. Cost was 5d. per kilowatt-hour, which, at the rate of 131 watt hours per foot drilled, is equal to ·655d. per foot. The minimum cost of drilling with steam or compressed air is equal to 5d. per foot.

(*e*) *Ventilation.*—There are not many instances as yet in this country of electrically-driven fans in mines. At the Pelton Colliery, Durham, a fan by Davidson and Co., Limited, of Belfast, has replaced two steam-driven Guibal fans. The fan motor absorbs about 154 b.h.p., removing 223,054 cubic feet of air per minute. On tests of Guibal fans the two removed 199,745 cubic feet of air per minute, and absorbed about 178 b.h.p. The gain in favour of the single electric fan of upwards of 23,300 cubic feet of air per minute, with an expenditure of 24 h.p. less—a reduction of 13·5 per cent.—is very creditable. Moreover, a set of boilers, burning coal, and two steam-engines were dispensed with, and an existing boiler fired with coke over gases was used.

(*f*) *Locomotives.*—Pneumatic locomotives are very clumsy affairs when compared with the excellent types of electric ones turned out by Messrs. Thomas Parker, Limited, and others. Their excess in bulk and weight is largely due to the big cylinders of compressed air which they must necessarily carry. In consequence they are not so suitable as electric locomotives for low seams, save where considerations of firedamp make their use the more safe. There must be sparking at wheels of compressed-air locomotives when skidding at starting or on gradients. It has been proved in South Wales that these sparks will ignite gas. Electric locomotives are not much used for collieries in this country, the sparking at the trolley wire being inadmissible, but even if compressed air is employed, electric driving is best for the compressors. In upkeep of locomotives electricity is far more economical than compressed air.

## The New Rules.

As was to be expected, a large amount of discussion among mining and electrical engineers followed the publication of the new rules, and the most divergent opinions have been expressed about them. The majority of electrical engineers seem to regard the rules as too arbitrary and of a nature to stifle enterprise in the necessarily gradual perfection of detail. Colliery managers in the main think that their individual responsibility is trodden upon, many having worked to their own rules for some time past. Now it is distinctly stated in Section XI. (1) of the rules that existing plants shall continue as they were, provided that an inspector agrees to their particular method of working.

Those mining engineers who have had little or no working experience with electrical plant are of opinion that the rules are too rich in electrical terms, and express their inability to understand them. One would certainly have thought that the mine manager of to-day would have made it his business to familiarise himself with the possibilities and main details of electric transmission. I believe that there are extremists in certain districts who regard the new rules as such complication extraordinary that they are actually waiting before putting down their electrical plant to see whether the new rules are made law. In view of this professed inability on the part of some mining engineers to understand the rules, and the unwillingness of the whole of that body to leave the matter entirely in the hands of the electrical men, a solution of the problem would seem to be the formation of a joint committee in which both parties would be properly represented. With reference to the proposed rules themselves, it is surely rather a standstill policy to limit the working pressure at the face to 650 volts for motors and transformers up to 75 kw. capacity. The judgment of the engineer, leavened by the advice of the inspector, should be quite satisfactory for the particular case. The rule as it stands must hamper progress. Section I., Rule 7 (5), states that none but authorised persons shall be permitted to enter the rooms in which motors and transformers are set apart. This also applies to generating plant under Rule 16 of Section II. Yet why should commutators and collector rings be fenced? An "authorised person" would surely be competent to adjust brushes, etc., and a fence would only be in his way. A man should be bothered as little as possible when doing this class of work.

By Rule 4, Section I., all live metal shall be covered or guarded. This is surely unnecessary in machine rooms where none but the authorised person may enter, but it is wise for the workings. It has been urged in opposition that the knowledge of the danger of touching live metal is a sure preventive for experienced men. But if such metal were not adequately guarded in the workings there would be many inexperienced men subject to such danger, and even the man of experience cannot have his eyes everywhere. With regard to Rule 9, Section I., it would be extremely difficult in a mine to limit the leakage current to one ten-thousandth of the maximum supply current. The measures presented in Rule 10, Section I.—viz., the subjection of the line and apparatus to a half-hour test at twice the maximum pressure—are surely too drastic; they would probably result in leaving a permanent strain. Rule 25, Section I., is to be highly commended. It is of great importance that a good practical knowledge of treatment for electric shock should be widespread throughout a mining installation.

Rule 3, Section III.—This rule, specifying the nature of cable tests, is a good one, and should go far towards ensuring that the user shall have no trouble with his cables other than from external causes, such as falls of roof, etc. Rule 6, Section III.—The stress laid here upon the prevention of moisture creeping at the ends of cables in terminals is of great practical importance. Many have learnt from unpleasant experience that the neglect of this point breeds trouble. In respect of motors (Section V., Rule 6), this rule absolutely specifies a slow-motion starter and a properly graded resistance for all classes of motors used in mining. One cannot imagine a good maker proposing to use any other type of switch for this class of work at the present time.

Rule 5, Section VII., stating that no wire carrying a current shall be used underground to support a lamp, etc., is a little strict for experienced men, and would be almost impossible to enforce. In any case it is well to bear in mind that H.M. inspectors of mines have powers under Section 42 of the Coal Mines Regulation Act, 1887, to

Digitized by Google

deal with any such special dangers as are not expressly guarded against in the new rules.

In conclusion, I would say that I have found the evidence given before the Commission on the Use of Electricity in Mines of great interest and value in the preparation of the paper. I would advise all interested to study both it and the Commissioners' report.

---

DISCUSSION.

In the discussion which followed, **Mr. Jackson** referred to a paper which had recently been read before the Rugby Engineering Society on "The Application of Electric Power in Collieries," by Mr. G. M. Brown. This paper embodied his views to a large extent. Where slip-ring motors were used, he recommended the use of more than one brush per ring, as this reduced liability of sparking. A frequency of 50 cycles per second was usually found most convenient.

**Prof. Redmayne** (Birmingham University) said that he favoured electricity as a motive power in mines. Steam and compressed air were, however, still largely used. Compressed air would continue to be a formidable competitor to electricity so long as there was any liability to sparking troubles with electric systems. Too much stress could not be laid on this question. In many cases its occurrence might result in an explosion. The author had quoted 30 per cent. as an efficiency figure in connection with compressed-air systems. Very old plants might show this figure, but modern systems, employing isothermal compression combined with reheating, had frequently an over-all efficiency as high as 70 per cent. But thermal efficiency was not such an important consideration as simplicity of apparatus. This was an absolute necessity in mining work, owing to the conditions of space and lighting. It was a moot point whether electricity or compressed air was the better system of power to use. In the majority of instances that had come under his notice, the quality of material and workmanship put into electric installations in mines and collieries was extremely good. With respect to drilling, it was a fact that electricity had absolutely failed to compete with compressed air as a motive power. There were several electric drills, more especially of the rotary type, that would do good work, but they were not suitable for mines. They were much more complicated than pneumatic drills, and more costly in upkeep. He hoped that a suitable electric drill would be designed. The figures quoted by the author to show the relative cost of different systems of coal-cutting could not be taken as reliable. To be of any value each system would have to be tried at the same spot, as the hardness of coal varied considerably even in the same pit.

**Mr. Reavell** (Ipswich) advocated air-compressors used in conjunction with electric generators at pithead, and electric distribution to different parts of the mine. This system would reduce first cost, and result in a greater economy of working than any other. The electric power might be used for all suitable work, such as pumping, etc. But pneumatic machinery was most suitable for coal cutting, drilling, etc., and the compressed air for these could be supplied by an electrically-driven air-compressor through short lengths of pipe. Coal-cutters frequently jambed. With a pneumatic tool it was a simple matter to cut off the air supply, withdraw cutter, and make a fresh start. But in the case of an electrically-driven machine it meant the replacing of a fuse, and a consequent delay. He then showed a lantern slide illustrating a portable electrically-driven air-compressor suitable for the work he had indicated. Another advantage resulting from the use of compressed air was its storage capacity. With a system entirely depending upon electricity, the generating plant had to have a capacity capable of dealing with the whole of the equipment. He condemned compression at the pithead, as it frequently resulted in the loss of 50 per cent. of the power generated.

**Mr. Gott** said that the argument of economy in fuel consumption might easily be overdone. In most mines there was a large amount of fuel unsuitable for sale that had to be got rid of, and which the mining engineer frequently consumed himself. Wholesale waste in pipes was consequently a minor consideration compared with convenience and economy of coal-cutting. Many engineers also considered that the loss due to friction in the shaft pipes was compensated for by the head. Commutator sparking was largely due to vibration. This should be reduced as much as possible by careful design. One of the troubles of electric distribution was the fact that in the shaft cables the core was liable to slip down the insulation. This necessitated a special form of suspension. A reference had been made to the running up of motors with generators; he wondered this was not more frequently used. A point the author had omitted was the necessity of lightning arresters where overhead wires were used for lighting and power transmission at the pithead. He instanced a case in which the omission of this precaution had necessitated the replacing of the shaft cables.

**Mr. M. B. Wild** regarded the choice of system as not settled by the question as to which was the cheapest to instal in the first instance, but by what system one could pull out the greatest amount of coal with ease and safety. He found that with direct-current plants considerably more power in motors could be put below ground than with alternating-current plants for a given power of generator on surface. Again, with direct current there was no trouble due to motors falling out of step, and causing stoppages, when the generator was momentarily overloaded. Direct-current motors properly designed for secondary haulage, and a suitable reversing controller with sufficient resistances, constituted an electric haulage gear as flexible as a steam or compressed-air hauling engine. There should be no necessity to use a friction clutch, which many electrical engineers had to do to get over defective starting gear, such as liquid switches and badly designed controllers. Another objection to liquid starting switches was that the liquid very soon evaporated, thus necessitating constant attention. Further, with direct current, supposing there was a stoppage for some time on a particular road, the speed could be increased considerably, so as to bring out the coal that had accumulated. A standard speed for single or double drum gears was five miles per hour, but they worked without any trouble at speeds varying from two to eight miles per hour. With an alternating-current system the speed of the motors could not be varied. For pumping and very large haulage—such as endless rope, main and tail with long runs—no doubt alternating current would be the better system. From personal experience he had every confidence in saying that in most collieries the haulage could be done by electricity, or in very fiery mines with compressed air generated by an electrically-driven compressor, placed as near as possible to the gears consistent with safety.

**Mr. H. M. Hobart** (*communicated*): "Continuous-current and polyphase systems have both been very successfully employed in the application of electricity to mines, and the relative merits of each system for any particular case should always be weighed before arriving at a decision. As the writer is satisfied that both systems will find wide fields of usefulness in such work, he does not propose to discuss their relative merits on this occasion, having recently done so in the discussion of Mr. Holiday's paper, entitled 'A Comparison of Three-Phase and Continuous Current for Mining Purposes,' read before the Institution of Mining Engineers, June 2, 1904. In those cases where the use of polyphase currents is most suitable, it is of paramount importance to employ a low periodicity, for it is the power applications which are of chief importance in mining, and any questions relating to the quality of the lighting are of secondary importance. Moreover, it is a fallacy to regard the question of lighting at low periodicities as offering grave difficulties. The lower the periodicity the lower should be the voltage chosen for the incandescent lighting circuits, and the higher should be the candle-power per single lamp, for by these means the carbon filament employed will be of sufficiently large section to be able to store the heat and obviate material reduction of temperature between the peaks of current of successive cycles. It will necessarily follow that the luminosity will then be more constant. But the chief desideratum, that of excellence in the design and performance of the motors, is enormously promoted by the use of low frequency. This will lead to higher power factors, lower magnetising current even with larger air-gap, greater overload capacity, and also cheaper motors, since for a given output the diameters will be smaller and the lengths greater. Capacity effects in the cables will also be decreased. The squirrel-cage type should be freely used, even in motors of large capacity."

**Mr. Anderson**, in his reply, admitted that steam was still largely used, but there was no doubt that the losses in the distribution system were of a most serious character. "Economy of coal-cutting" was impossible with a "wholesale waste in pipes." Undoubtedly mining engineers, as a body, regarded fuel economy as of considerable importance. The modern electrical equipment of collieries was very good in most cases, but bad early work had been prejudicial to progress of electricity in mines. The electrical equivalent of the compressed-air storage system was the battery—a most convenient factor. It was a very difficult matter to obtain reliable comparative figures of coal-cutting performances, as the conditions of working were so various. The replacement of fuses in connection with coal-cutters driven by polyphase motors was of rare occurrence. Liquid rheostats were very good as starters. For variable-speed work the ordinary type of regulator would be used. The advocacy (Mr. Hobart's) of a low frequency was very interesting, but the low voltage necessary for successful lighting would hardly conduce to the best economy. The system of starting motors by running up with the generator added considerably to the capital outlay, as separate circuits were necessary. He agreed with the remarks that had been made about the necessity of employing machinery of as simple a nature as possible.

---

## THE PROTECTION OF ELECTRICAL INSTALLATIONS BY MEANS OF LIGHTNING ARRESTERS CONNECTED IN SERIES.

The following description of a new type of lightning arrester constructed by the Allgemeine Electricitäts A.G. to designs by Mr. Gola is given in the *Elektrotechnische Zeitschrift*. If an overhead line is provided with lightning arresters, A, B, C, etc. (either of similar or dissimilar types and with varying lengths of spark-gap), at points *a*, *b*, *c*, etc., along its length, observation has proved that the action of the different arresters will be very irregular. Sometimes several will work at once, sometimes none will act. Out of a number of exactly similar arresters, perhaps only one will act, and in some cases this will be the least sensitive arrester. These occurrences indicate that the action of an arrester depends more on its position on the line than on its construction, and this may be accounted for by the wave-form propagation of the discharge. If, for instance, at a certain discharge into the line a wave summit happens to occur at *a* and a node at *b*, the arrester A will act, whilst B will remain unaffected. If all the arresters on the line happen to lie in the neighbourhood of nodes, none of them may act, in spite of the occurrence of a heavy discharge which may be quite capable

Digitized by Google

of breaking down the insulation of the generators. A discharge in general travels along the line until it arrives at some interruption. Since the generator almost always forms one of the chief interruptions to such waves in the circuit, its position affects the whole distribution of the waves in such a way that a wave summit is formed at that point, and in this way numerous breakdowns of generators may be accounted for. If several lightning arresters are distributed along the line, it is, of course, likely that at least one will act whenever a lightning discharge occurs, though it is by no means certain. Certainty can only be arrived at by employing some form of apparatus which will ensure a wave summit occurring just at the point where an arrester is connected. Mr. Gola's arresters effect this by forming an interruption in the circuit similar to that formed by a generator. The apparatus is inserted in the line from the machine, and beside it an easy discharge path to earth is provided. The arrester has no appreciable impedance for the ordinary alternating currents, and acts as a filter or sieve which allows the generated current to pass, but not the high-frequency atmospheric discharge.

The construction of the apparatus is shown in Figs. 1 and 2. Two large covers, A and B, made of magnetic material, are separated by a rim, F, of non-arcing metal, and the whole is held together by bronze bolts. The non-arcing metal forms a rim, separating the two covers all round, and is fitted with an internal cross-piece, G. Two other covers, C C, also of magnetic material, surround the first-named covers, and are connected to them by small bolts. These outer covers carry a soft iron core, D,

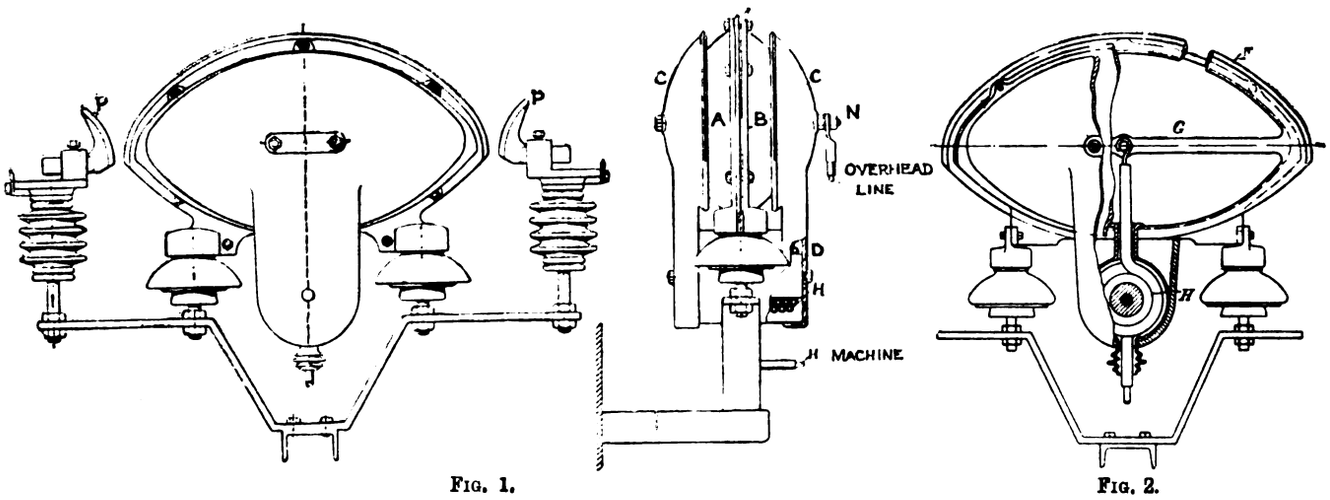

FIG. 1. FIG. 2.

surrounded by a coil, H. One end of this coil is connected to the middle point of the cross-piece, G, and the other end is brought out of the apparatus. Two separate insulators at the sides carry the earthed horns, P P, and the whole is mounted on a V-shaped arm. The length of the spark-gaps is adjustable. The incoming line is connected to the terminal, N, on one of the outer covers, C C; whilst the line leading to the machine is connected to the free end of the coil, H. The discharge must, therefore, pass from the outer cover, C, through the connecting bolts, which offer a path of very small section, to the covers, A B, traversing magnetic material, and, finally, by way of the cross-piece, G (also of small cross-section), through the coil, H. Such a path forms, as is well known, a great hindrance to the passage of high-frequency currents, and the apparatus, therefore, has a choking effect, and forces the atmospheric discharge to jump across to the carbons, P. The formation of arcs to earth after a discharge may be prevented by the insertion of carbon resistances between the horns, P, and earth.

## MANCHESTER TRAMWAYS.

The paper read by Messrs. S. L. Pearce and H. C. Gunton before the Manchester Section on Feb. 21, on "The Manchester Tramways and Power Supply," was hardly expected to provoke much comment, as the paper itself consisted largely of plain statements of fact and statistics of seemingly local interest only. The paper, however, contrary to expectations, brought together a good gathering, and provoked a lively discussion.

The CHAIRMAN (Mr. C. D. Taite) commented upon the difference in power taken by the large and small cars, and referred to the advantages of condensing, which the curves showed to be a 25 per cent. saving. He considered that the efficiency of the sub-stations was poor, and enquired if the capacity of the motor generators was to blame, and if rotary converters would not have been better? A cheerful and encouraging point was the total works costs for the lowest month in 1904, of ·27d. for Stuart-street, ·28d. Bloom-street, and ·432d. at Dickinson-street. He thought that the figures proved the possibilities of the greatest economy with large stations, to the disadvantage, by comparison, of small stations.

Mr. L. ANDREWS referred to the solid and indisputable matter contained in the paper. He drew attention to the peculiar features of the curve which combines the two loads for lighting and traction; and the load factors also showed the advantage of a combination of the two classes of supply in one station. He differed from Mr. Taite as regards the sub-station efficiencies, and pointed out that the 78 per cent. average monthly conversion efficiency was good for all-day running. He had had a very much lower efficiency on single-phase working of only 50 to 60 per cent. He calculated the cost of current generated at sub-stations to be about ·4d. per unit, and agreed with Mr. Taite as to the impossibility of touching this figure on small systems. He was not certain if the ·103d. per unit generated referred to the total cost of distribution or of delivery to sub-stations. He compared the interesting figures of ·17d. per unit on condensers against ·26d. non-condensing, the saving being perfectly convincing. The advantages of superheated steam in connection with the reciprocating tests of 19·8lb. per unit generated and 17·2lb. was apparent, but how much extra coal was used to obtain the 90deg. F.

Dr. RHODES observed that the main factor to be considered was the maximum traction, and this could vary as a ratio within wide limits to the plant capacity. The beauty of Manchester (from a strictly engineering standpoint) was its exceeding flatness, which, together with the large extent of the system, explained the efficiency of the combined station arrangement. He instanced Oldham as almost the other extreme, with its precipices of 1 in 10 and its much smaller car service.

Mr. SEATON was jocular at the expense of the tempting figures instanced, and thought that the 2lb. of coal per unit generated was incredible, because human engine builders only soared as low as 2½lb.

Mr. ORZETICH enquired regarding trouble with the switching in and out of the motor-generators from static effects? His experience was that beyond 250 kw. the size of unit could not be increased economically.

Mr. J. FRITH would have preferred to have heard more regarding the dark side of the undertaking, as the most valuable knowledge was gained from unhappy experiences. He also enquired regarding the use of compound-wound generators for combined stations.

Mr. T. W. SHEFFIELD believed that traffic considerations should govern the use of large or small cars in preference to cost per car mile.

Mr. S. J. WATSON, from practical experience, advocated combined stations. He asked for an explanation of the two ·5 cables used as traction feeders. Were they in parallel, or used as lead and return? Also, were the high-tension feeders specially regulated.

Mr. M. B. FIELD thought that the overload capacity of generators should be mainly determined by the heating effect. In one instance he noted that the station was overpowered by 50 per cent. of its plant capacity, but he considered that this was quite safe, and that motor-generators should not get out of

Digitized by Google

phase under 100 per cent. overloads of a temporary character. Batteries would help to a certain extent in reducing the heating effect. He was curious as to the reason for the length of time (up to half an hour in Glasgow) the abnormal demand lasted after a total breakdown of the car service. In Glasgow with negative boosters he more than satisfied the Board of Trade requirements by keeping his difference of potential under one volt.

Mr. A. G. COOPER pointed out that under certain circumstances batteries could reverse a compound-wound generator, and that the requirements for regulation of feeding voltage on lighting and traction loads were somewhat different. He referred to the smaller wage item per passenger on large cars, and thought that the seven-volt limit for rail drop was quite enough.

Mr. C. C. ATCHISON despaired of obtaining figures comparable to Manchester with his gradients at Rochdale, and anticipated a figure nearer 25 kw. per car than 8·5 kw. Coventry was an example of a combined station that was successful by making use of its traction extensions to further extend its lighting area, and enquired if Manchester did likewise? Were the Manchester return feeders in parallel with the rails or were they taken straight back?

Mr. PEARCE, in reply, stated that the ·1031. was the total cost of distribution. He could give no official figures for coal on the superheating test, but the figures for the condensing tests were 3·2lb. against 4·1lb. non-condensing. Parallel running in Manchester had been quite satisfactory. Increasing the size of motor-generators was of little advantage. He had experienced no trouble upon the system, except as to mistakes in winding of machines of an easily remediable character. He used chokers for induction motors. He would like to know what Mr. Firth expected to gain by the use of compound-wound generators for lighting? His high-tension feeders ran from two to seven miles, and were not regulated. The tramway rails were nowhere connected to the generating station, the return feeders connecting them only to the sub-stations. The return feeders could be substituted for the positive feeders in case of need, and all these feeders ran together with this object. Although running in parallel upon overload with care was safe enough, he was quite satisfied with 50 per cent. as a maximum overload.

## STEAM-TURBINES.

**A paper on "The Mechanical Construction of Steam-Turbines and Turbo-Generators" was read by Mr. W. J. A. London at the Manchester Section meeting on the 28th ult., and was discussed as follows:**

The CHAIRMAN (Mr. C. D. Taite) said that the subject was of increasing interest. There were many books published on the subject, but little experience had been gained in running. He hoped the paper would be followed by others dealing with those points which time limitations had prevented enlarging upon. He wished to know if the makers of vertical turbines concurred with the comparisons given in the paper.

Mr. NEILSON thought that great credit should be given to the British Westinghouse Company for allowing so much valuable and exclusive information to be published. Few firms were given to that sort of thing.

Mr. T. L. MILLER wished to know more regarding one of the weak points of steam-turbines—the attaching of the blades. He had been greatly struck with the strongl mechanical construction of the B.T.H.-Curtis turbine, and considered the blades to be the soundest possible type, as they are cut out of the solid. The blades could be examined at any point by opening a door and revolving the disc. As regards the chance of trouble on vertical turbines where the lubricating arrangements failed, he suggested that a hydraulic accumulator feeding the footstep bearings would meet the difficulty, but did not know if this was in use anywhere. The acknowledgment in the paper of vibration difficulties was interesting, as it was commonly thought there were none. Wet steam should be guarded against, as it was liable to flood the machine and bring it to a stop. This was mostly experienced where superheated steam was not used.

Mr. BAILEY gave some dimension details of the vertical machines at Harrogate. He had experienced vibration troubles, but prevented their permanence by intercepting the conducting path *vid* metal joists, etc. Concrete was not to be trusted as a foundation, owing to its shrinkage. A girder foundation was quite satisfactory if properly designed. Some people put a couple of bare girders down under a machine, and then called it erected. They should be properly braced together, however, to ensure rigidity. He had only balanced half a dozen turbine spindles in 11 years' experience with Parsons turbines. The chance of cylinder distortion mentioned only required thicker metal to obviate. He pointed out that the Westinghouse type of double-flow turbine had been used early on by Parsons, but was eventually rejected on account of its lower efficiency and greater length. He desired to know what had been the cause of trouble in connection with the Westinghouse machines made for the Metropolitan Railway?

Mr. H. LINDLEY had also been impressed by the superior mechanical strength of the vanes in the Curtis turbines, which combined simplicity and solidity. He pointed out that the horizontal turbines were in the same boat (as regards oil-pump breakdowns) with the vertical machines. Cotton-mills in Manchester were driven by steam-turbines quite satisfactorily.

Mr. F. H. WHYSALL could say nothing on the matter from a maker's point of view, but had had a considerable experience with the running of turbo-generators, and agreed with the paper in stating that the partner that gave most trouble was the generator, although this was not an excessive amount. The Manchester Corporation machines had run for three winters satisfactorily at 6.000ft. per minute speed of commutator, which only required turning up every 20 months. Superheating had increased the working temperature from 130deg. to 150deg. F. at least, but no trouble had been caused. His experience was that vibration could be entirely eliminated by balancing the rotating parts.

Mr. SEATON pointed out that while wet steam merely temporarily slowed down turbines until got rid of, it was absolute death to steam-engines.

Dr. BOWMAN had used hydraulic accumulators instead of pumps for oil lubrication bearings. He likened the turbine to the Welsbach mantle, which has extended the use of gas by a little while, the turbine likewise lengthening the days of steam-engines somewhat.

Mr. J. FRITH was struck by the statement that carbon brushes cannot be used on continuous-current turbo-generators on account of the armature floating when running, and thus causing the brushes to dance. He pointed out that the copper brush consumption added considerably to the total costs.

Mr. MILES WALKER, as being responsible for the design of the generator portion of the machines, replied to Mr. Bailey's enquiry as to the Metropolitan Railway turbines, by stating that these machines had run without a single stoppage, and were never shut down unless required. If, however, Mr. Bailey's reference to trouble applied to the workshop experiments, he was willing to admit that a large number of practical experiments had been made to determine the best design, and, naturally, some of these had been failures. He thought Mr. Parsons was also a believer in practical experiment, from the number he had made. In any case, a reasonable man would judge a machine by its performance under working responsibility, and not by workshop experiments. Other makers of blades had been so much praised that evening that he felt bound to mention that the 50 per cent. over-speed tests upon Westinghouse machines had failed to affect a single blade. There was the disadvantage in the Curtis solid blades that if these got wiped off (as was very possible in handling and erecting them), it meant a new wheel altogether. With carbon brushes half-a-thousandth of an inch play caused chattering, but a metal brush gave flexibly.

Mr. C. C. ATCHISON agreed with the paper in distrusting a single vertical bearing on account of non-lubricating possibilities. He preferred the water-jacket bearing for turbines, and had had to employ a man and water-buckets for attending to bearings where water-jackets were not provided.

Mr. A. G. COOPER, as regards lubrication difficulties, stated that he could not bear his hands on his turbine bearings after working two hours, but considered no harm could be done if good oil was used—in fact, any degree of heat was safe up to the melting point of the metal or the carbonising temperature of the oil. He understood that Siemens made a carbon-brush machine for Bristol, but this was not perfectly successful, and the design was altered.

Mr. W. J. A. LONDON, in reply, repeated his faith in concrete foundations. The Westinghouse blades had a factor of safety of 10. As regards conductance of heat upward from Curtis turbines to generators, he pointed out that although externally this might be balanced by the fan effect, internal radiation still existed. He did not approve of the thicker metal in cylinder walls suggested—cylinders must have ribs. The works test on a 2 000-kw. machine, 27in. vacuum, no superheat, was 18 6lb. per kilowatt-hour. He could mention several stations where Parsons machines were running with bare wire binding. The spindles could easily be straightened if bent. The quality of oil used was important. Machines were often shut down by using cheap lubricant, and sometimes this had to be chipped out of the bearings. With the drop-forged blades suggested it would be impossible to get the same clearance as with the machined blades, these being polished and buffed for absolute evenness. Carbon brushes chatter, and eventually break. They might suit if made in very small pieces, so as to more closely follow the movements of the commutator.

Mr. E. W. COWAN, in proposing a vote of thanks to Mr. London, deprecated Mr. Bailey's allusion to the Metropolitan machines, and pointed out that turbine makers should hang together if they wished their type of prime mover to have a chance against other classes of engines.

## ELECTRIC TRAMCARS v. MOTOR 'BUSES.

Competition between electric tramways and petrol-driven motor 'buses alone can decide which is the fitter to survive, but we see every reason to believe that these two rivals may in the end prove to be of mutual advantage to each other. At present the competition on paper is very severe, but there are not enough figures available respecting the cost of running and upkeep of motor 'buses to make reliable conclusions on the subject. Interesting contributions to this controversy appeared in the *Liverpool Daily Post* the other day from Mr. J. R. Salter (engineer-in-chief of the South Lancashire Tramways Company) and Mr. E. A. Rosenheim (engineer to the Liverpool Road Carrying Company), consequent upon a motion of which notice had been given by Councillor Wilson, urging that the Tramways Committee of that town should "consider and report upon the desirability of introducing self-propelled motorcars or omnibuses to work in conjunction with or apart from the present system of electric cars." The arguments advanced by the former in favour of electric cars are those which have now become familiar, but they lose nothing in force from the cogent manner in which Mr. Salter marshals them. He emphasises the economy in power when running on rails, especially where severe gradients are concerned. Again, while it is necessary on any vehicle carrying its own generating plant to provide machinery sufficient to produce the maximum effort required, an electric power station, being designed to deal with the average effort, enables the greatest possible economy and efficiency to be obtained from the plant at the lowest possible cost for production of power. On many tramway systems in this country power is produced for less than ½d. per Board of Trade unit, which will propel a car for about a mile. Then the limited seating accommodation of the motor 'buses would necessitate the number being doubled as compared with the trams, thus increasing traffic congestion and danger. Mr. Salter estimates that in some parts of the city division of Liverpool it would be necessary to have practically a continuous string of motor 'buses, which would enormously increase the perils of the pedestrian. Last year, with the trams carrying 113,000,000 passengers, only four pedestrians met their death. Mr. Salter contends that the saving on permanent way is completely neutralised by the heavier cost of constructing motor 'buses—reckoning it as three times that of the electric car—and the greater number that would be requisite. It is in the cost of operation, however, that Mr. Salter considers that the electric tram shows itself so immeasurably superior to the motor 'bus. The power costs, even providing for interest and sinking fund and depreciation upon the generating plant, are less than the cost of power for operating the motor 'bus. Again, the cost of maintenance of the motor 'bus is much greater than the cost of maintenance of the electric tramcar. The great number of moving parts in a petrol engine, the excessive vibration and jarring due to the minutest variations in the level of the road, and the fact that it is necessary, whether the motor 'bus be in motion or not, to keep the engine running, all tend to shorten the life of the vehicle, and to involve tremendous charges for maintenance and depreciation. Besides this, the smaller seating capacity of the motor 'buses means a corresponding increase in the number of motormen and conductors. Then, again, there is the question of tyres, the replacing of which he estimates will represent a cost of at least 2d. per car mile—a greater sum than is usually required to meet the whole of the maintenance charges on an electric tramway undertaking where there is a frequent service. In conclusion, Mr. Salter claims that the total operating costs with

Digitized by Google

motor omnibuses are treble those with electric cars. Mr. Rosenheim, while admitting the advantage of the electric car in regard to seating accommodation, places the cost of the motor 'bus at less than double that of the electric car, and contends that this will leave a substantial margin in favour of the former, as regards capital costs. His estimate of £700 to £900 for a motor 'bus appears a moderate one. With respect to running expenses, Mr. Rosenheim puts the figure for the tramcar at 6d. to 7d. per mile, against 9d. per car mile for the motor 'bus. There is, of course, little available data in regard to motor 'buses, but the estimate of 9d. seems a flattering one. In regard to earning capacity, he mentions that in the case of the only motor 'buses from which data are available the earning capacity is 1s. 3d. per car mile, against 10d. for the Liverpool trams. It is premature, however, to speak positively of the earning capacity of motor 'buses, besides which the frequency of the Liverpool tram service has to be taken into consideration in making this comparison. Mr. Rosenheim concludes by denying that the cost for repairs and maintenance of tyres will be anything like so great as that asserted by the advocates of the electric car, but does not give any figures. We think the case presented by Mr. Salter, however, substantially demonstrates that the electric tram in large towns or for regular interurban traffic has little cause to fear its new rival. There are, however, cases where tramways cannot be employed without making street improvements at prohibitive cost. In such cases and for infrequent services the motor 'bus has advantages which may outweigh the higher running costs. What is really needed to settle the controversy is experience, after extended trials under commercial conditions, of the cost of upkeep of heavy motor vehicles running at good speeds. Such experience will soon be available, but in the meanwhile there is no valid reason for suspending the construction of electric tramways.

## BRIDLINGTON ELECTRICITY WORKS.

### Opening Ceremony.

The formal opening of these works took place on Thursday, March 2. The ceremony was performed by his Worship the Mayor, Alderman C. E. Field, J.P. Councillor Mainprize, the chairman of the Electricity Committee, called upon the town clerk to present the mayor with a beautifully designed gold key, bearing a suitable inscription, the arms of the borough, and his own initials. The Town Clerk, Mr. A. E. Matthewman, said that this was the first occasion since the charter day that such a presentation had taken place in the borough. In presenting the key he pointed out that the souvenir represented an expenditure of nearly £30,000, and the ceremony it inaugurated was a big event in the history of Bridlington. The Mayor briefly acknowledged the gift, emphasising in his remarks the practical method in which the consulting engineer had carried out his work. In its early days, he confessed, he had viewed the undertaking with something akin to pessimism, but from the encouragement that he had from private consumers, who numbered about 90, he ventured to prophesy that the undertaking would be a success from the very first. This it surely would be if everybody who could would come forward to assist. He emphasised the specially low rate of charge (5d. for ordinary consumers, 4½d. for users of 500 units per quarter, and 4d. for users of 1,000 units per quarter), and also was proud to state that Bridlington was the first town in the country to electrically light the streets throughout the whole borough. He then opened the door with the gold key presented by the town clerk, declared the building open, and a large number of councillors, visitors, and ladies inspected the station.

The special feature in connection with the new station is the switchboard governing the street lights, from which all the arc and incandescent lights are operated by means of solenoids placed in street boxes at intervals along the streets. The station, which is exceedingly well built and lined throughout with white glazed tiles, is very well arranged, with a considerable amount of space all round for extending when necessary.

Various refreshments were served most liberally until 5.30, when the assembly gathered in the engine-room, and the Mayor introduced Councillor Mainprize, the chairman of the Electric Lighting Committee, who in a speech delivered from the switchboard gallery held out the various advantages to be gained by using electric light, especially in a health resort, and also gave a *résumé* of the station equipment and the fine work carried out by the contractors. He further held out prospects of electric traction in the near future, emphasising the need of a tramway service from Bridlington to Flamborough.

Alderman Johnson and Councillor Andrew, whose duties consisted of starting up the two engines, then spoke at some length, and darkness was fast falling when the stop valves were at last opened, and the current was switched on by the chairman amid loud applause. The act was successful, and during the evening the streets were perambulated by appreciative crowds examining the new light.

A dinner, at the invitation of Messrs. Medhurst, Page, and Lloyd, was held after the opening ceremony at the Brunswick Hotel, which was attended by most of the councillors and a large number of contractors' representatives and visitors.

MR. A. J. BECKETT, BOROUGH ELECTRICAL ENGINEER, BRIDLINGTON.

After the toast of "The King and Royal Family," proposed by the Mayor, had been drunk, Mr. Medhurst, the consulting engineer, proposed the toast of "The Mayor and Corporation" The Mayor called upon Alderman Sawden to respond, by reason of his commanding flow of speech. The alderman sustained his reputation, and the next toast, "The Success of the Electric Light Undertaking," was proclaimed by the chairman of the Gainsborough Urban District Council.

Mr. A. J. Beckett, who has acted as clerk of works and now takes charge of the undertaking as borough electrical engineer, has had extensive experience. He commenced as a pupil of the Brush Electrical Engineering Company at the Falcon Works, Loughborough, leaving at the end of two years to go through a year's course in the Siemens Laboratory at King's College, London. He returned to the Brush Company as assistant engineer in the erection of the central stations at Hanley, Dover, and Sheffield. He then supervised for the British Insulated Wire Company the laying of mains at Southport, Leicester, Yarmouth, and Bolton. He afterwards designed and put down the entire plant for the Fairhill Brick and Tile Company, of Bedford, on the completion of which he was appointed assistant engineer at the Belfast Corporation electricity works, leaving Belfast to take up an appointment under the York Corporation, where he for four years acted as mains and works superintendent. Last year Mr. Beckett was appointed clerk of works to the Bridlington Corporation electric lighting undertaking, and on the completion of the works

Digitized by Google

he was appointed borough electrical engineer by the unanimous vote of the Council.

## THE FOG LOAD.

A fog may be regarded as a dispensation of Providence to try the moral fibre of engineers in charge of electricity supply. The process is attended by the discovery of many of the weak points of the supply system, both in the station and throughout the network. Unless special work is proceeding on the mains, however, the stress is chiefly felt in the station, with the possible exception that spare transformers have to be switched in, and fuses commence to blow through overloads. A fog warning in a station is, in fact, equivalent to the drumbeat to general quarters on board a man-of-war previous to a hot engagement. And, particularly during the winter months, constant readiness for such a visitation is necessary. The blackness of great darkness which overspread the city of London on Friday week should act as a solemn warning to all station men who had been prematurely rejoicing that peak-load worries were over for a season. It is probable that Friday provided for most of the metropolitan supply companies a demand that was all load and no peak.

The condition of readiness for such sudden loads includes attention to two classes of essentials—those things which must not be done, and those which it is imperative to do. As regards the first class, it is necessary not to be in too much hurry to begin overhauling the plant before fine weather is assured. There is doubtless a great temptation, when the light of day grows bright, showing up the wear and tear of the winter, to lay off a boiler or engine for thorough examination and repair. It is, however, necessary to be conservative in this respect, as although it is sometimes possible in dire extremity to close a pipe with a soft wood plug instead of a blank flange, or to rig up a tangle of temporary dynamo connections, it is not so easy to throw a Willans engine together, or to put one or two hundred caps on the headers of a Babcock boiler. For the same reason it is not always true economy to be a hard taskmaster, discharging all hands not absolutely essential at the first hint of spring. If there are too many stokers, it is better policy to put the spare men on minor repairs than to turn them on to the street. It is wiser to sanction extra expenditure of polishing paste on the engine-room than to tell the greasers to look out for another job. Labour is cheap just now, but it is always convenient to have men about the place who know how to run the plant without being drilled, even if they are not so engaged for six or eight months together.

As regards the things to be done, it is advisable, first of all, to have a perfect watch kept. At the Bankside station of the City of London Company there is, we understand, an ancient mariner stationed somewhere on the roof whose duty it is not merely to watch the smoke emission of the station, but to use his weather lore for the benefit of those considerably beneath him. Indication of fog is immediately communicated to the engineer in charge of the running at the time, who is thereby enabled to prepare for excess load. Where it is impossible for stations, owing to their small size, to pay a man exclusively for this duty, it is a useful scheme to get an undertaking from three or four consumers at different parts of the town, whose occupations compel them to take notice of the weather (such as van owners, or such shopkeepers as fruiterers, who display their goods partly in the street), to ring up the station on the telephone at the approach of bad weather.

Whatever means are taken to give warning, the engineer in charge should immediately make sure of his boiler-house, as this is usually where the greatest delay takes place If automatic stoking gear is used, the mechanisms should be tried, to see that they are in working order, and if by experience it is found that a considerable time elapses before the grate is properly covered with fire in regular working order, as with some forms of coking stokers, the engineer is wise in being prodigal with fire-lighting material. It is better to waste a little coal than to have the lights low. There should, of course, be a spare boiler standing with fires banked in any case, and if a fog load is anticipated it is well to supplement this by one or two others.

In the engine-room the system of trial should be proceeding as regards such auxiliary gear as separately-driven air-pumps and other plant that may not have been in use for some time, with the steam and water valves, traps, and drains belonging to the engines. Warming steam should at once be put on the main sets, oil-cups should be filled, and as far as possible sight-feeds should be regulated before running up, and the engines barred over and placed on their turning centres ready for action. It is well for the engineer to assume that every part of the plant is going to be used, and to take his precautions accordingly. Penny-wisdom is pound-foolishness in this case. In times of peace the running staff should be trained to this "emergency drill," so that a critical situation may be dealt with promptly. Fitters and their labourers throughout the station should be warned to get the plant they are working on into condition for immediate use, and to be ready to clear out of the way at a moment's notice. Even if the plant is not used, the exercise will do the fitting staff good. The station lights should be at once seen to. A good light saves many a panic. Then, after a final exhortation to the leading stoker to keep up his "pecker" and his steam, and a warning to the head driver not to lose his head, the engineer in charge may get on to the switchboard ready to take flying shots with the synchronising gear, in the full assurance that even if the lights should after all become red-hot hair-pins, he has done his best to get ready for trouble.

It may be urged that such great preparations are expensive, and savour of panic. A real fog, however, is not to be treated lightly. More lights have been "out" through foolhardiness in the station than the outside world dreams of. A more reasonable objection is that sometimes a fog descends with such suddenness that the engineer has no time to make any preparation. In such case he must trust in Providence and see that the oil-swabs are being used.

## RESIGNATION OF MR. W. A. CHAMEN.

At a meeting of the Electricity Committee of the Glasgow Corporation held on 2nd inst., the following letter, dated Feb. 28, was received from the chief engineer, Mr. W. A. Chamen:

"I have to inform you that I have decided to accept an offer which has been made to me of a position of responsibility with the well-known firm of consulting engineers, Messrs. Bramwell and Harris, of London, Edinburgh, and Cardiff. It will be a favour to me if the Corporation can arrange to relieve me at an early date of my engagement to serve them as I have done for upwards of seven years past in the position of their chief engineer and manager of the electricity department of the Corporation, instead of waiting for the expiration of the three months' notice which under the terms of my engagement I am legally bound to give. In the meantime, I beg leave formally to give this three months' notice of the termination of my engagement, to put the matter in order. I wish to take this opportunity of expressing my sincere thanks for, and appreciation of, the courtesy and kindness I have always been able to rely upon at the hands not only of the Lord Provost, magistrates, committees, and other members of the Corporation, but also of the citizens of Glasgow in my relationship with them. In addition to my indebtedness to the Lord Provost and Corporation, and to those they represent, I cannot close my connection with Glasgow in an official capacity without tendering my regret to yourself and my brother officials of the Corporation that the offer I have received necessitates my losing the assistance they have always in our official work so readily given me, though I trust the friendly relations which have always existed between us may not be forgotten or entirely terminated."

Bailie Willock, in moving the approval of the minute spoke at some length of the excellent work which Mr. Chamen had done in Glasgow, and of how under his guiding hand their electricity undertaking had been guided past the dangers that beset such undertakings at their beginning, and their electricity department, if it had not yet reached the Bay of Plenty, it might be said to be within sight of it.

Mr. Chamen is well known throughout the length and breadth of the electrical world, and the outstanding facts in his career have been published time and again in various technical journals. He is still a young man, comparatively speaking, being just over 40 years of age. The experience which he has had both during the time he has occupied his present position and during the previous 17 years when he was with the firm of Crompton and Co., should be of great

Digitized by Google

value to the firm of Messrs. Bramwell and Harris in the inception and development of electricity power schemes and any kindred work.

When Mr. Chamen went to Glasgow the electricity supply was all generated in one small generating station in Waterloo-street, the pressure of supply having been just recently changed from 100 volts to 200 volts on a three-wire system—*i e.*, having only 100 volts on each side. The capital expenditure at that time had reached the sum of £188,000, and the revenue was £36,000. The total horse-power available was 3,300. At the present time two large new generating stations are in operation, one dealing mostly with that part of the city which lies on the north side of the River Clyde, and the other mostly with the area on the south side of the river, there being, however, a certain amount of trunk connection between the two. The total horse-power at the present moment, including the small electricity works purchased from the Kelvinside Company some four or five years ago, is 18,330. Mr. Chamen decided to use 200lb. steam pressure, which, although common enough now, was seldom to be met with seven years ago, and various unpleasant predictions were made regarding the departure. The declared electricity pressure was raised to 500 volts—*i e.*, 250 volts in consumers' premises for lighting. Concentric three-wire mains were introduced from the start of the new work

MR. W. A. CHAMEN.

These concentric mains included one square inch triple-concentric feeders, a size of cable which up to that time had never been made, and great anxiety was expressed as to the possibility of success with it. The idea also of using concentric distributing cables at all for continuous-current work in such a large city as Glasgow was freely criticised, and trouble was predicted. In all these matters unqualified success has crowned Mr. Chamen's pioneering efforts. The latest development has been in the ordering of steam-turbines for the large extensions of generating plant now in hand. One of these turbines is arranged to drive two 700-kw. continuous-current 500-volt dynamos, and the other two are being constructed to drive alternators of 3,000 kw. capacity each, the current being three-phase with a periodicity of 25 cycles per second and at a pressure of 6,500 volts. Two sub-stations, using induction motor-generators for conversion, are already in operation, one being situated in the old generating station in Waterloo-street, from which all the steam plant was removed some two years ago. In addition to the special points already named, Mr. Chamen decided to take a departure in the matter of low-tension switchboards, arranging these with the object of preventing proximity of large differences of potential, and making a complete departure from the usual practice of cramming the whole controlling arrangements as close as possible together. The same principle has been followed as far as possible in the laying out of the new high-tension switchboard at Port Dundas. Considerable attention has been given to the question of power supply development, so that at the present time there is about 9,500 h p of motors coupled to the mains. The capital expenditure upon the undertaking is now, in round figures, £1,300,000. The revenue for the present year ending May 31 is expected to approximate £190,000.

During his stay in Glasgow Mr. Chamen has occupied various important offices in connection with technical and other societies. In the year 1901 he was made president of the Incorporated Municipal Electrical Association, the convention for that year being held in Glasgow. Up to the present time he remains one of the most active members of council of this association. He joined the Institute of Engineers and Shipbuilders in Scotland shortly after his arrival in Glasgow, and was soon made a member of council, which office he still holds at present in the capacity of one of the vice-presidents. Mr. Chamen has, of course, for many years been a member of the Institution of Electrical Engineers, and was one of those who were instrumental in starting the Glasgow Local Section of that body. He was chairman of this section for the session 1903 4. He has been appointed at various times to sub-committees of the Institution, and is also at the present time a member of the Prime Movers and other sub-committees of the Engineering Standards Committee. He is a member of the Royal Philosophical Society of Glasgow, and for the past winter he has been president of the Glasgow University Engineering Society, which body has elected him an honorary member on the occasion of his leaving Glasgow.

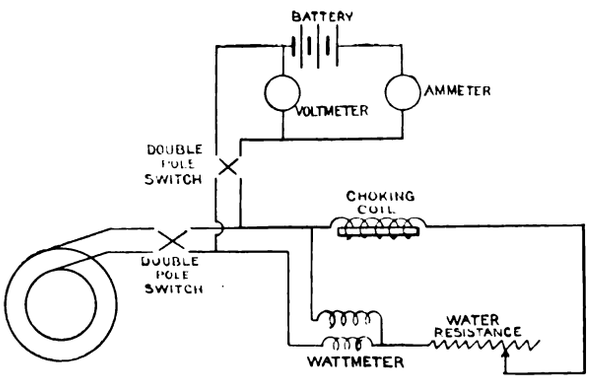
We wish Mr. Chamen every success in the new work he is about to take up.

## THE VARIATION OF POWER WITH RESISTANCE IN AN ALTERNATING-CURRENT CIRCUIT.

BY E. P. HOLLIS.

I was conducting an experiment on the variation of power in an alternating-current circuit when a remarkable phenomenon occurred which attracted my attention. A small alternator was supplying power to a circuit which consisted of an adjustable water resistance, a choking coil, and a wattmeter. The plates of the water resistance were as far apart as possible—*i e*, all the resistance was in circuit. The wattmeter was indicating very little power, and as I moved the plates nearer together the reading on the wattmeter slowly rose, but whilst I was still moving the plates nearer together the reading seemed to attain a maximum value, and then suddenly commenced to fall, and continued to do so until the plates were close together, when the wattmeter reading was practically zero.

I therefore connected up an auxiliary circuit in order to obtain the value of the resistance in circuit. This is shown in the accompanying diagram. It will be seen that if the

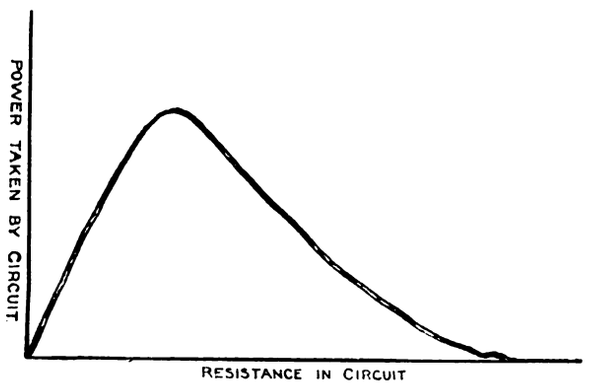


alternator circuit be opened and the auxiliary circuit closed, a current, A, passes through the circuit, consisting of the choking coil, water resistance, and wattmeter. If V be the drop in volts across the circuit, as indicated on the voltmeter, it follows from Ohm's law that the resistance of the circuit is given by $\frac{V}{C}$.

Now, I varied the distance apart of the plates in the water resistance, and at each position noted the power passing through the circuit as indicated by the wattmeter,

Digitized by Google

and then opened the alternator circuit and closed the battery circuit, and thus obtained the resistance of the circuit as given above. I then plotted a curve with these results, the shape of which I give below. I then proceeded to investigate the subject mathematically in order to find what was the value of the resistance in circuit at which the maximum power was taken, with the following result.



Let us consider the circuit to have a coefficient of self-induction L henrys and a resistance of R ohms. Let E be the alternating E M F. applied to the circuit, C the current passing, and cos $\phi$ the power factor.

Then the power taken by the circuit is

$$W = E\,C\cos\phi \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Now the current passing through the circuit can be expressed by

$$C = \frac{E}{\sqrt{R^2 + p^2 L^2}} \quad . \quad . \quad . \quad . \quad (2)$$

where $p = 2\pi \times$ frequency

and

$$\text{Cos}\,\phi = \frac{R}{\sqrt{R^2 + p^2 L^2}} \quad . \quad . \quad . \quad . \quad (3)$$

Substituting 2 and 3 in 1 we get

$$W = E\,C\cos\phi = \frac{E \times E}{\sqrt{R^2+p^2L^2}} \times \frac{R}{\sqrt{R^2+p^2L^2}},$$

$$= \frac{E^2\,R}{R^2+p^2L^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Now it is required to find how the power in the current varies with the resistance. To do this we must differentiate the expression 4 with respect to R—*i.e.*,

$$\frac{d\,W}{d\,R} = \frac{E^2\,(R^2+p^2\,L^2) - E^2\,R \times 2\,R}{(R^2+p^2\,L^2)^2},$$

$$= \frac{E^2\,(p^2\,L^2 - R^2)}{(R^2+p^2\,L^2)^2} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Now, the power in the circuit is a maximum when $\frac{d\,W}{d\,R} = 0$, or when $\frac{E^2\,(p^2\,L^2 - R^2)}{(R^2+p^2\,L^2)^2} = 0$. It will be seen that this expression will become zero when $p^2\,L^2 - R^2 = 0$—*i.e.*, when $R = p\,L$.

Thus *the maximum power is obtained in an alternating-current circuit when the resistance is equal to the reactance.*

## CHIMNEYS.

BY F. H. DAVIES.

As the efficient working of all natural-draught steam-raising plant is dependent greatly upon the manner in which its chimney has been designed, it follows that too much attention cannot be paid to the various minutiæ of the subject. Undoubtedly many steam installations are severely handicapped by unsuitable chimneys that, either through a false idea of economy or ignorance of the fundamental laws governing the generation of a draught, have been made too small, or are in some other way incapable of performing the necessary amount of duty. As the function of a chimney is two-fold—namely, the creation of a draught and the carrying off of the gaseous products of combustion—it must be considered under both heads, the first of which requires height and the second area. Several formulæ have been given for determining these two fundamental measurements, but as the problem is beset by many difficulties that vary considerably with local conditions, they are all of a somewhat empirical nature, being based upon observations of successful work.

The intensity of draught is dependent upon the difference in weight of the internal column of air and an imaginary external one of the same height and equal in diameter to the former at its smallest cross-section. The higher the chimney, therefore, the greater will be the force of its draught. This is measured in inches of water by the aid of a U tube, one end of which is left open to the atmosphere and the other connected to the interior of the chimney at its base. The difference in level of the water in these two legs shows the strength of the draught, which is found in practice to vary between $\frac{1}{4}$in., indicating a rather poor draught, up to 1in. or over, equivalent to a very strong one. A usual formula for finding the theoretical draught in inches of water when the height is given is the following: $7{\cdot}6\,H \times \frac{T_2 - T_1}{T_2 \times T_1}$; H being the height in feet, $T_1$ the absolute temperature of the atmosphere, and $T_2$ the absolute temperature of the chimney gases. The result will be the required figure in inches of water. In designing a chimney it is usual to fix the height more or less arbitrarily, basing it upon previous practice, and with this quantity known, it becomes easy to calculate the area from one of the usual formulæ. That due to Kent is very commonly used, and is as follows: $A = \frac{{\cdot}06\,F}{\sqrt{H}}$; where A = actual area in square feet, H = height in feet, F = pounds of coal per hour that will be consumed. From this it is obvious that the quality of the coal is a factor to be taken into consideration, as the value of F will vary with it for any given load; hence, for safety, a chimney should be designed to deal with the worst coal that is ever likely to be burnt in the furnaces. There must be, of course, a certain amount of friction between the escaping gases and the lining of the chimney, and this has been estimated to result in a layer of gas approximately 2in. thick adhering to the sides, and therefore appreciably reducing the effective area to a value below that of the actual area. The formula $E\,A = A - 0{\cdot}6\sqrt{A}$ is used for determining the effective area, A, the actual area in square feet having been found as above. Another useful formula is that due to Christie. It is handy for determining the maximum horse-power of plant that any given chimney is capable of providing draught for, and is based upon the assumption that 4lb. of coal are consumed per horse-power hour. Using the same notation as previously, it is as follows: $H.P. = 3{\cdot}24\,A\sqrt{H}$.

It is common knowledge that a draught that will suffice for the proper combustion of one kind of coal may be quite inadequate for another; hence it follows that the sort of coal most likely to be used enters into the question of height as well as that of area. Good bituminous coal requires the least draught, and therefore the lowest chimney, and small anthracite may be taken as the other extreme. Nothing under 70ft. in height is of much value with natural draught, even for a very small plant burning the best bituminous coal, and it is better by far to err upon the side of unnecessary height, as this allows more scope for forcing and in the variety of coal that may be used.

In the actual shape and building details of the chimney there is much to be considered. The nature of the materials of which it is to be composed, either brickwork or steel, its foundations, shape, stability as regards wind pressure, and other details, all of great interest and importance, enter into the question. In this country the brick chimney is by far the commonest, but in America both the stayed and self-supporting steel type are very much in vogue. They are each cheaper than a brick chimney in capital cost, but having to be repainted once a year to save deterioration through corrosion, add an amount to maintenance that in small plants is somewhat heavy and disproportionate. A well-built brick chimney requires no repairs for years, and then only such as are of a trifling nature; consequently, it is preferred by many despite its capital cost and the

Digitized by Google

fact that the steel shaft is slightly more efficient, owing to the entire absence of the leakage that is always going on through the pores of bricks and mortar. If, however, considerations of capital cost must outweigh those of revenue, the firebrick-lined steel chimney is the thing; the unlined variety need not be considered, as owing to radiation it is inefficient in the extreme.

There are two kinds of these stacks, self-supporting and stayed; the former is preferable from the point of view of appearance, and is, indeed, the only type that can be used for large work owing to staying difficulties, but it costs rather more than the latter variety, having to be much more substantial in every way. The stayed form is generally used in small power plants, being very cheap as compared with a brick shaft, and giving equally as good results if brick lined. It is built of iron or steel in cylindrical sections, which are usually lapped and riveted, although sometimes butted with a covering piece riveted on. The foot of the chimney is bolted to a heavy ring placed upon a substantial brick base, generally as high as the building, and this forms the first stage of the shaft. Wire guy ropes, usually four in number, are taken off some three-quarters of the way up by means of a ring provided with hooks or suitable attachments, and fastened through turnbuckles to bolts sunk well into the building structure.

The design of a brick chimney is a much more complicated matter than that of its steel prototype, for here various external and internal shapes are possible, whereas the cylindrical is the only form that the latter can be adapted to. Although, perhaps, the hexagonal chimney presents the most pleasing appearance, for a given area it has a smaller capacity than a circular one, and, in addition, exposes more surface to the overturning power of the wind. It is not, however, so bad in either of these respects as the square chimney, the internal corners of which introduce considerable resistance to the outflowing gases, and the flat external faces a comparatively large area to be acted on by the wind. This overturning force is naturally one that has to be taken into full consideration, and, with a given wind pressure, it will, of course, vary with the shape of the shaft, whether round, hexagonal, or square. For this reason, a certain relation must exist between the height, width, shape, and weight of a chimney; and given these three former, the latter may be found by the following formula. Where C = a constant for the various shapes—28 in the case of round, 35 octagonal, and 56 for a square chimney—H = height in feet, D = average diameter, B = breadth of base, and W = weight in pounds, $W = C\frac{D H^2}{B}$.

The proper proportioning of the foundations of a shaft is of the greatest importance, as its future welfare largely depends upon this. All proceedings must be based upon a thorough knowledge of the bearing power of the soil, which varies much with its nature. Usual practice defines the safe weight per square foot at one ton for soft clay and two tons for stiff clay or lightly packed sand; but if the soil is at all marshy, efficient piling must be resorted to.

The external diameter at the base of a brick chimney should not be less than one-tenth of its height, and the batter or taper usually allowed is from $\frac{1}{16}$in. to $\frac{1}{4}$in. on each side. The internal diameter should not vary appreciably from base to top, and the firebrick lining that is always provided is built up straight with no batter, thus leaving an air-space between it and the outside wall. This lining generally extends from two-thirds to three-quarters of the total height, although in cases it is carried to the top. In the event of two flues entering a chimney at different sides, it is always desirable to build a feather or mid-wall between them to about a quarter of the height, so that the gases from each have a separate path to start with. If this is not done, they are liable to baffle each other as they emerge from the flues, and this may cause a considerable diminution in the efficiency of the chimney.

The usual thicknesses for the outer shell of a brick shaft are as follows: shaft up to 3ft. internal diameter at top—4in. for first 10ft. downwards, after this an increase of 4in. at every 25ft.; shaft over 3ft. and not more than 5ft. internal diameter at top—8in. to start with, increasing by 4in. for every 25ft. downwards; shaft over 5ft. internal diameter at top—12in. to start with, and same increase. The inner firebrick lining may be 4in. thick for the first 20ft. or so, increasing by 4in. at every 10ft. downwards.

## FORTHCOMING EVENTS.

FRIDAY, MARCH 10.

**Institution of Electrical Engineers (Manchester Section).**—At 7 p.m., annual dinner.

**Royal Institution.**—At 9 p.m., "The Structure of the Atom," by Prof. J. J. Thomson.

SATURDAY, MARCH 11.

**Junior Institution of Engineers.**—At 3 p.m., visit to the New Ritz Hotel, Piccadilly, to inspect the "cage skeleton system" of constructional engineering.

**Birmingham Electric Club.**—At 7 p.m., "Electric Lifting Machinery," by Mr. E. C. R. Marks.

**Royal Institution.**—At 3 p.m., "Electrical Properties of Radio-active Substances," by Prof. J. J. Thomson.

**Institution of Electrical Engineers (Students' Section).**—At 2.15 p.m., visit to Messrs. D. Napier and Sons' works, Acton Vale.

MONDAY, MARCH 13.

**Institution of Mechanical Engineers (Graduates' Section).**—"The Type of Locomotive Best Suited to Heavy Express Trains," by Mr. J. R. Bazin.

**Society of Arts.**—At 8 p.m., "Telephony," by Mr. H. L. Webb (Cantor Lecture I.).

TUESDAY, MARCH 14.

**Institution of Electrical Engineers (Glasgow Section).**—At 8 p.m., "Earthing" by Mr. W. W. Lackie (adjourned discussion).

**Institution of Electrical Engineers (Manchester Section).**—At 7.30 p.m., "Low-Tension Thermal Cut-outs," by Prof. Schwartz and Mr. W. H. N. James.

**Institution of Civil Engineers.**—At 8 p.m., "Shipbuilding for the Navy," by Lord Brassey.

WEDNESDAY, MARCH 15.

**Institution of Civil Engineers.**—At 2.30 p.m., students' visit to the sewage works at Sutton, Surrey. Train from Victoria Station, L.B. and S.C. Railway, 1.45 p.m.

**Institution of Electrical Engineers (Birmingham Section).**—At 7.45 p.m., "Commutation in a Four-Pole Machine," by Mr. J. K. Catterson-Smith; and "Notes on Heating and Sparking Limits in Variable-Speed Motors," by Mr. A. H. Bate.

**Chemical Society.**—At 5.30 p.m., general meeting.

**Royal Meteorological Society.**—At 7.30 p.m., "The Growth of Instrumental Meteorology," by the President.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m., "Electrical Pyrometry," by Mr. P. L. Weir.

THURSDAY, MARCH 16.

**Institution of Electrical Engineers (Leeds Section).**—At 7.15 p.m., "Power Gas," by Dr. F. H. Bowman.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m., annual dinner at the Holborn Restaurant.

**National Physical Laboratory.**—At 3.30 p.m., annual general meeting at Bushy House, Teddington.

FRIDAY, MARCH 17.

**Institution of Mechanical Engineers.**—At 8 p.m., "First Report to the Steam-Engine Research Committee," by Prof. D. S. Capper.

**Institution of Electrical Engineers (Manchester Students' Section).**—At 7.30 p.m., "High-Tension Switchgear," by Mr. C. R. St. John.

SATURDAY, MARCH 18.

**Institution of Electrical Engineers (Manchester Students' Section).**—At 6.30 p.m., annual dinner.

**Institution of Civil Engineers.**—On March 22, at 7 p.m., annual dinner at Merchant Taylors' Hall. Sir Guilford Molesworth, president, in the chair. The thirteenth "James Forrest" lecture will be delivered by Colonel R. E. B. Crompton, R.E., C.B., on Monday, April 10, at 8 p.m., the subject being "Unsolved Problems in Electrical Engineering."

**Royal Meteorological Society.**—An exhibition of meteorological instruments is to be held by this society at the hall of the Institution of Civil Engineers, from March 14 to 17. A brief descriptive address will be given each afternoon at 3.30.

## APPOINTMENTS VACANT.

**First Assistant Electrical Engineer,** City of Wakefield. Salary, £150 per annum. Applications by March 14. See advertisement in last issue.

**Switchboard Attendant,** Wrexham. Commencing salary, 25s. per week.

**Chief Electrical Engineer,** Bermondsey Borough Council.

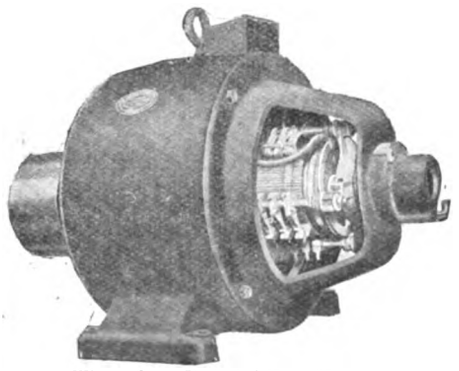
**Chief Draughtsman,** Bombay, Baroda, and Central India Railway Company (carriage and wagon department). Salary, Rs.250, rising to Rs.300 per calendar month. Particulars may be obtained from Mr. T. W. Wood, secretary, Gloucester House, Bishopsgate-street Without, London, E.C. Applications by March 22.

Digitized by Google

## TRADE NOTICES AND NOVELTIES.

### Witton Motors.

The General Electric Company, Limited, 71, Queen Victoria-street, London, E.C., have just issued a new edition of their catalogue of continuous-current motors. These motors have, we understand, been entirely remodelled, and have a high rate of efficiency. The firm's works at Witton, Birmingham, where they are made, is now thoroughly equipped for turning them out in large quantities. The list is illustrated, and gives particulars of the open-protected, semi-enclosed, enclosed-ventilated, and totally-enclosed types; also of crane rated motors, back-geared motors, etc. Our illustration represents the first-

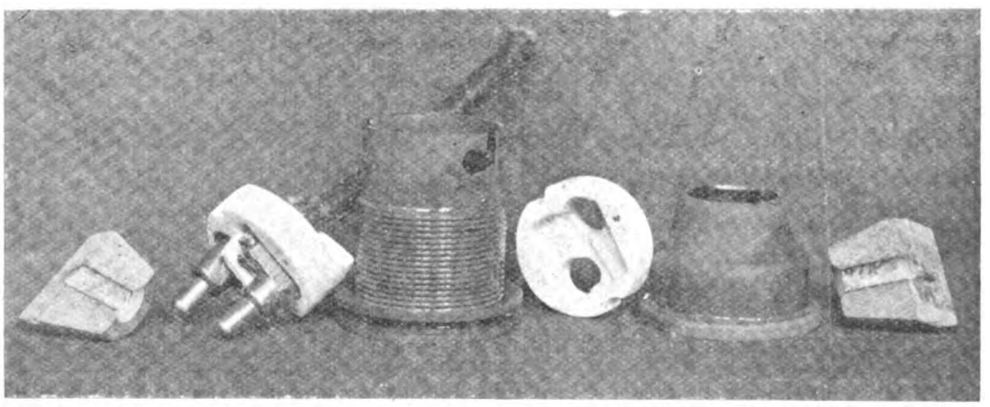


Witton Open Protected Type Motor.

mentioned type. All parts are made to gauge and strictly interchangeable. Spares can therefore be supplied quickly whenever necessary. The design of the bearings is such that the motors can be fixed on a horizontal base, a vertical wall, or overhead. We note that the measurements are given both in inches and centimetres, and the weights in pounds and kilos. The approximate power required to drive various classes of machinery is also given—a fact which should be appreciated, especially by users of small motors. At the end of the list an illustration is given showing "Witton" motors being fitted to winches for "Temperley" transporter towers destined for the Admiralty floating coal depôt stationed at Portsmouth.

### New Lampholder.

We are indebted to Messrs. Baxendale and Co., Miller-street Works, Manchester, for particulars and sample of a new cord-grip lampholder called the "Thikflex," which is being introduced by them. Referring to the accompanying illustration of its several components, it will be seen that the case of this holder is in two parts. These screw together, and interlock the cord grip, china interior, and terminals with each other, so



Parts of "Thikflex" Cord Grip Lampholder.

that it is impossible for them to be twisted, or become detached in any way whatever. The china interior, also in two parts, is so constructed that when put together the terminals, which are not permanently fixed to the china, are held quite firmly in position, and are entirely insulated from each other and from the case, no metal being exposed beyond the plungers themselves. Moreover, the terminals being separate parts, are easily wired. When the holder is wired and made up, the cord grip cannot possibly be twisted, and retains such a firm hold on the flexible that all strain is taken off the connections. The size of the cord grip allows a large variation in adjustment for different thicknesses of flexibles. These various points, it is claimed, go to make up a first-class, substantial, and efficient English-made cord-grip holder, particularly suited for factories, workshops, cotton and woollen mills, where rough usage or other severe conditions have to be encountered. Personally, we think the design is one which will find ready favour, since it obviously combines several excellent features.

### Nernst Lamps.

The latest catalogue of Nernst lamps issued by the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., includes particulars of several recent improvements. A new pattern multiple Nernst lamp is shown on p. 10. This is a combination of three lamps in one watertight fitting, suitable for outdoor use, and is designed to replace the arc lamp where an even distribution of the light is required. The light ranges between 60 c.p. and 820 c.p., according to circuit, and whether the three burners, Luna or "A" type, are switched on separately or together. On p. 14 a new type "D" is illustrated, which is similar in appearance to the firm's "B" pattern, and, like it, will fit ordinary B C or screw holders. Being of high luminating power, this lamp is eminently adapted for street-lighting purposes when enclosed in a lantern. Improvements in reflectors for "B" type Nernst lamps are illustrated on p. 21. These reflectors are recommended for indoor use, being of very neat design. We note that progress has also been made with Express Nernst lamp fittings and electroliers. The incandescent lamps combined with these serve to give light immediately the lamps are switched on, being cut out automatically as soon as the Nernst filament is alight.

### New "Twinkling Socket."

Advertising by means of an effective electric sign has been handicapped up to the present time by the high initial cost of an installation suitable for this purpose, due to the expensive automatic switches and large amount of wiring involved. To obviate the necessity for special installation the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., have, we understand, lately put on the market a device which they call a "Twinkling Socket." This special socket is one that can be fixed into an ordinary lampholder, and can be used for incandescent lamps of 10 c.p. or 16 c.p. and 110 or 220 volts. It is devised so that when the current is switched on the lamp is cut in and out quickly and continuously at regular intervals. If the sign be fitted with a number of these sockets a most effective result is obtained, it is claimed, each lamp being cut in and out independently, the effect being that the whole sign appears to be twinkling or flickering.

### Asbestos Strip.

We note that the United Asbestos Company, Limited, Dock House, Billiter-street, E.C., are supplying a special kind of asbestos in the form of a thin strip for insulating the sections of electric car rheostats. It is called "Salamander" insulating strip.

### Catalogues, etc., Received.

Reduction Gear.—A list issued by Messrs. J. S. Fairfax and Co., 37 and 39, Essex-street, Strand, London, W.C., describes the firm's new types of reduction gear to drive directly from a motor shaft at one of six different ratios; pulley shafts of two, three, or four pulleys, equal in diameter, each revolving at a different forward or reverse speed to its neighbour; and a compact pulley block convertible to a self-sustaining hand crane.

Roller Bearings.—A list recently issued by the Empire Roller-Bearings Company, Limited, 15, Victoria-street, Westminster, S.W., includes illustrations and particulars of the firm's speciality; also a list of the railways and tramways on which their bearings are now in use.

Injectors.—The latest descriptive list of injectors issued by Messrs. Holden and Brooke, Limited, Sirius Works, West Gorton, Manchester, includes information to assist the user in selecting the right size of injector required, the conditions governing this selection being set forth.

Ship Installations.—From Messrs. J. H. Holmes and Co., Newcastle-on-Tyne, we have received an up-to-date list of the ship and yacht lighting installations carried out by them. It serves to convey an idea of the immense amount of experience which the firm have had in this special class of work.

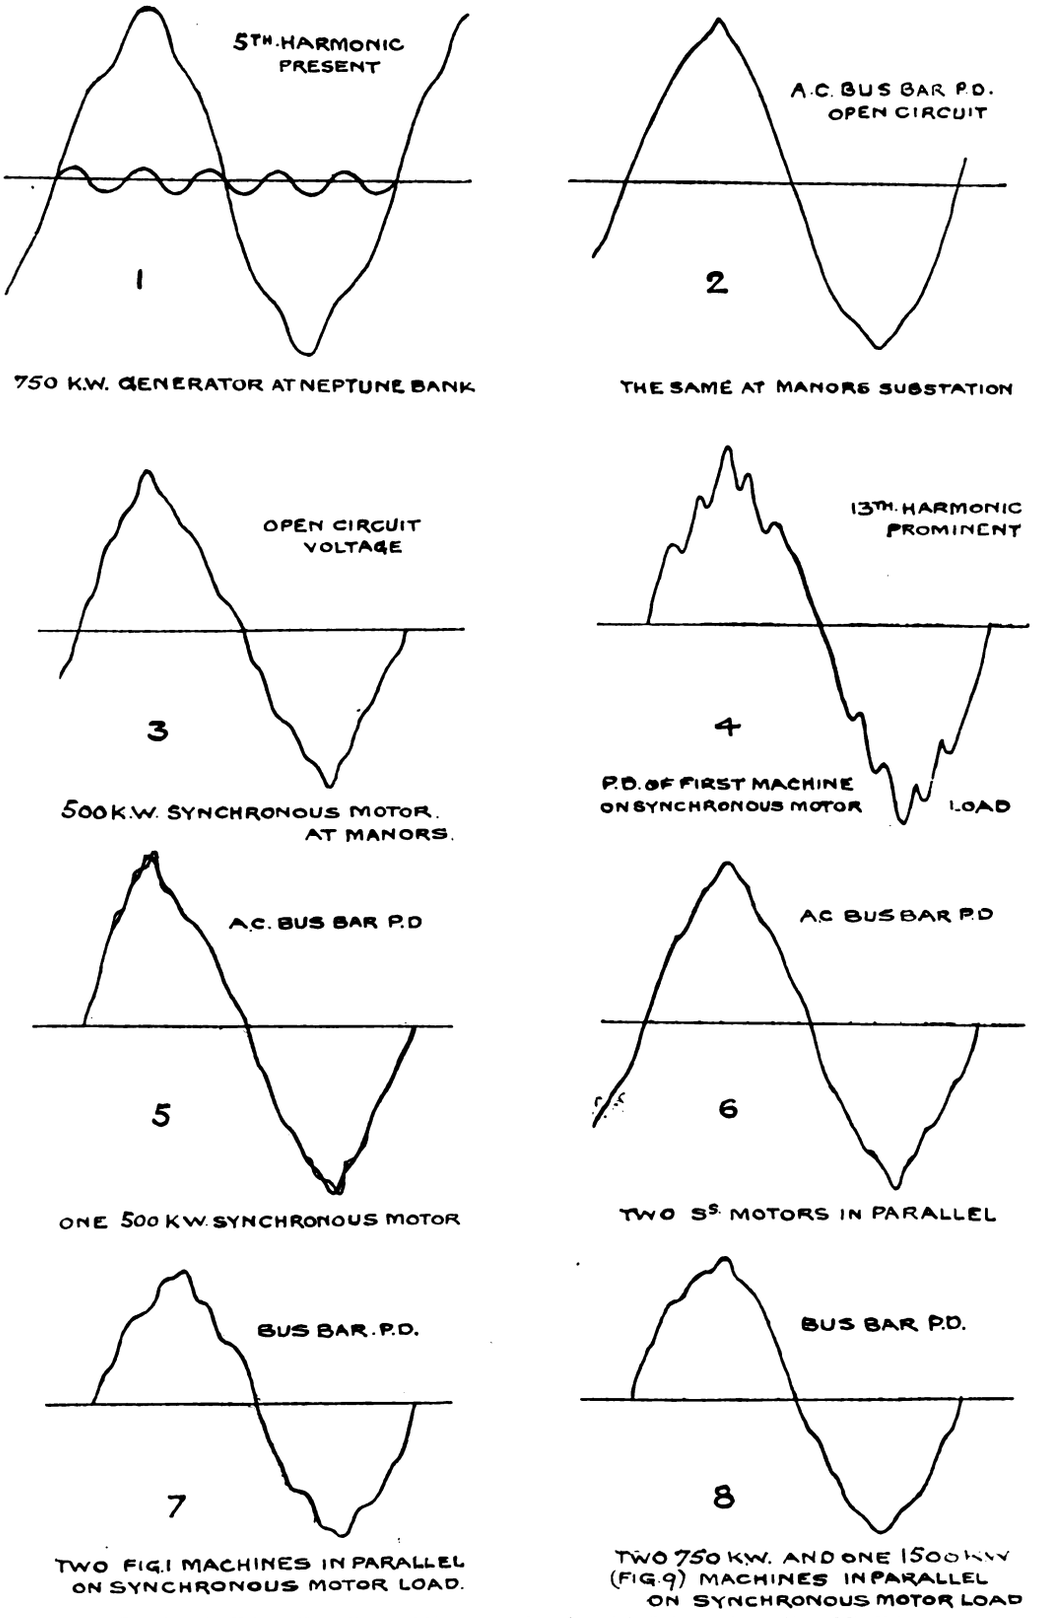
## NOTES ON SOME EFFECTS IN THREE-PHASE WORKING.*

BY W. M. THORNTON, D SC., MEMBER

§ 1. INFLUENCE OF CABLES ON TRANSMITTED WAVE-FORMS.

The behaviour of a polyphase electrical transmission system under working conditions presents many interesting problems. Through the kindness of the Newcastle-on-Tyne Electric Supply Company, I am able to give the results of some investigations with the oscillograph which were undertaken with the object of deciding, for this particular system, a few questions of importance in the regular working of the plant. The interest of the curves lies in the fact that they were taken under working conditions, in the absence of any abnormal phenomena, in the comparisons between different machines, and in the addition of a few more facts to our knowledge of polyphase working on a large scale. The tests were suggested by Mr. H. C. Leake and Mr. W. B. Woodhouse, and all the details were in their hands throughout. They were taken in three sets—in December, 1901, March, 1902, and July, 1903.

From the curves recorded I have selected those which throw light upon points of more than local interest. For example, it was desired to know whether the wave-forms at the sub-station were distorted by the mains. Fig. 1 is the voltage on open circuit of a General Electric (U.S.A.) 5,500-volt 750-kw. three-phase generator taken at the Neptune Bank power-house. Fig. 2 is the same wave at Manors sub-station, a length of three miles of three-core cable intervening. Analysis of the first curve shows that there is present a strong 5th harmonic. This machine has one slot per pole per phase, and, as is well known, six slots per period give rise to 5th and 7th harmonics in the voltage. Here the former predominates. It is clear from the second curve that there is little distortion



FIGS. 1 TO 8.—Voltage Wave Forms of Three-Phase Machines, R.M.S. Value of each Wave 5,500 Volts.

* Paper read before the Newcastle Local Section of the Institution of Electrical Engineers, Feb. 27.

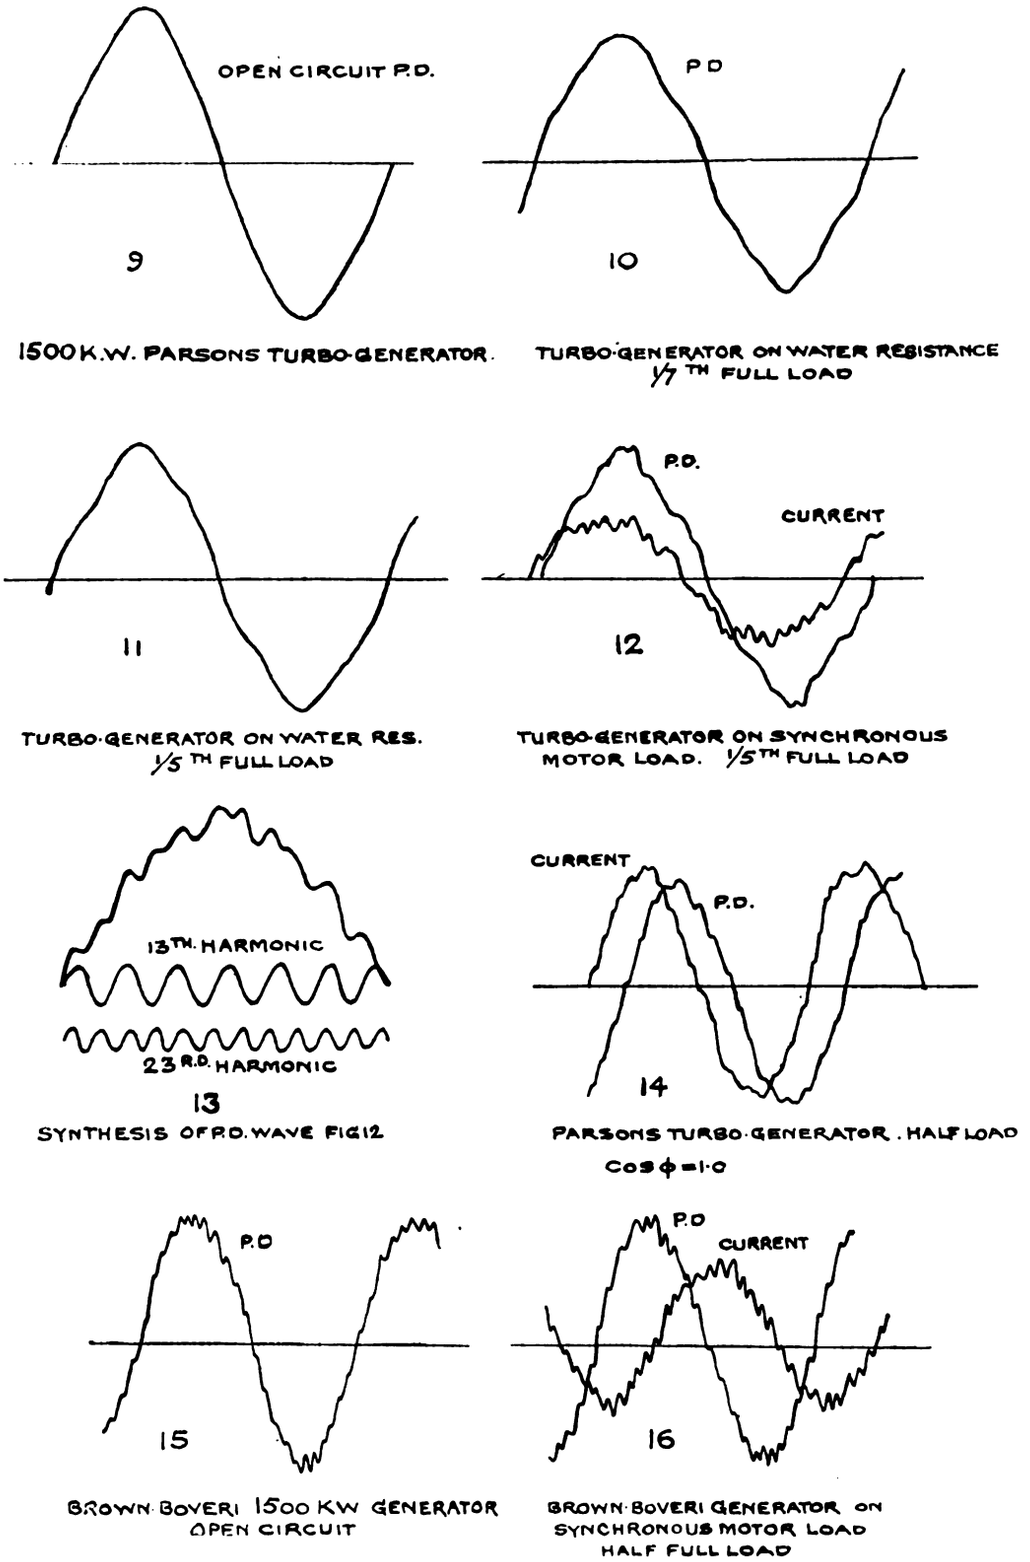
Digitized by Google

by the capacity of the cables; the tops of the waves are slightly more pointed, but there is no fear in this case of trouble arising from resonance.

§ 2. Influence of Synchronous Motor Load upon Wave-Form.

There is, however, the possibility of danger arising from the synchronous motor waves if they have strong harmonics. Fig. 3 is taken from a 500-kw. motor-generator set at Manors, driven from the direct-current side as a three-phase generator on open circuit, and is typical of all the motors in the system. alternating-current side, the ripples are smoothed out. In Curve 6 the superposition of 5th and 13th is clearly seen.

Another proof that the ripples came from the reaction of the synchronous circuit is that they appeared to run up and down the curve in time with the engine driving the generator. If they had arisen from this machine they would have been fixed, but since its phase is swinging slightly, by reason of the engine irregularity, with respect to the circuit voltage, they move along the wave, the amount of movement indicating precisely the range of the relative phase-swing between generator and



Figs. 9 to 16.

The machine has two slots per pole per phase, causing a well-marked 13th harmonic. The generator curve (Fig. 4) is the power-house wave of the same machine as in Fig. 1, but now running on a synchronous motor load at Manors. Although in this generator the 5th harmonic is most pronounced, the voltage appears with a 13th prominent, more marked, in fact, than on the motor, an effect possibly due to the mains, but more likely to the double-frequency phenomena explained in the next section. In Fig. 5, which is the 'bus-bar voltage at the sub-station when one synchronous motor is running light from the motor. The visible motion is slight on account of the small scale of the curves, or this would be a suitable method of measuring phase displacement between machines, either motors or generators, in parallel, having somewhat different wave-forms, by observing only the 'bus-bar voltage. In Fig. 5 the tips of the curves waved to and fro in time with the engine. The relative movement of the machines in this case corresponds to 17deg. of phase, the mechanical movement depending on the diameter and number of poles on the rotor of each machine.

Digitized by Google

Even when several generators are in parallel, as in Figs. 7 and 8, the motor harmonic is able to make itself felt at the power-house, though less so as the number of machines is increased.

A still better example is the reaction upon a Parsons turbo-generator. This machine gives a very fine curve (Fig. 9) on open circuit. It has, however, two slots per pole per phase, and the 13th harmonic is now just visible in the generator wave. On a water resistance (a circular brick tank, into which dipped three iron plates forming the inside surface of a symmetrical clover-leaf pattern, rigidly connected and raised or lowered together by a single pulley), there is some distortion, which increases with load (Figs. 10 and 11). In this case, however, it is the 11th harmonic which appears, suggesting that the occurrence of either harmonic is a question of armature reaction. Fig. 12 shows the wave-form of this machine on a synchronous motor load, and there is now a pronounced 13th harmonic. The current is full of a 23rd harmonic. This cannot readily be seen in the voltage, but a wave (Curve 13) may be built up of a fundamental 13th and 23rd, which approximates in wave-form to that of Fig. 12. As the load increases the higher harmonics predominate (Fig. 14).

That these high ripples do not entirely arise from double-frequency effect of armature current reaction may be seen from Fig. 15, taken from a 1,500-kw. Parsons turbine Brown Boveri generator set on open circuit, the machine having four slots per pole per phase. In this curve a 23rd can be counted. When the machine is on load there is a slight change in the voltage wave, but the current shows the 23rd harmonic much more clearly (Fig. 16).

(*To be continued.*)

## PERSONAL.

Elsewhere in this issue will be found a reference to Mr. W. A. Chamen's resignation of the position of chief engineer and manager to the Glasgow Corporation electricity department in order to take up larger responsibilities in connection with power distribution schemes. At a meeting of the Electricity Committee held on 7th inst., Mr. Lackie, Mr. Chamen's chief assistant, was unanimously recommended for promotion to the post of chief engineer and manager, Mr. Page, the stations superintendent, being recommended for promotion to the post of chief assistant. The salary recommended for Mr. Lackie is £800 per annum, rising to £1,000, and for Mr. Page £500, rising to £600. These recommendations are, of course, subject to confirmation by the Town Council on the 16th inst. Mr. Charles A. King, permanent-way engineer of the Glasgow tramways, has been appointed to a similar position on the Metropolitan District Railway.

Mr. Duncan McLennan, of Glasgow, has been assistant mains superintendent to the Corporation of Greenock.

Mr. W. W. Alston, assistant engineer to the Bermondsey electricity and destructor department, has been appointed chief assistant engineer to the West Bromwich electricity works.

We have received the following particulars of a wedding: "Leigh-Humbert—On the 1st inst. at St. John's Church, Stanmore, by the Rector of Stanmore, Mr. Frederick A. Cortez Leigh, of the firm of Messrs. Lacey, Sillar, and Leigh, to Dorothy, only daughter of the late Sidney Humbert, of Watford."

The special committee of the Exeter City Council have reported as follows: "The committee, after careful enquiry, are fully satisfied with the competency of Mr. Munro as an electrical engineer, and are of opinion that the electrical engineer should have charge of all the works in connection with the electric light undertaking, including mains, and of the electrical equipment in connection with the tramways."

The Dover Town Council have granted a number of increases to the staff of the electricity department.

We understand that Mr. Theodore Partington, electrical engineer at Pemberton, has resigned.

The Dewsbury Town Council have decided to increase the salary of Mr. A. P. Dryburgh, assistant electrical engineer at the electricity works, from £150 to £170 per year as from April 1 next.

Mr. W. H. Vincent, borough electrical engineer, Bermondsey, has resigned.

Mr. Rycroft has been appointed chief assistant electrical engineer, and Mr. Margary mains superintendent, to the Islington Borough Council.

Mr. Ernest Hatton, general manager of the Salford Corporation tramways, has been appointed to a similar position at Newcastle-on-Tyne.

The West Ham Council have increased the salary of the tramways manager (Mr. H. E. Blain) by £50, with a further increase in August next of £50 and a second increase in February, 1906, of a further £50.

JOINT-BOXES, ETC.—From Messrs. G. Clark and Sons, Limited, Shipley, Yorks, we have a copy of their new catalogue of joint and disconnecting boxes and fittings, feeder pillars, etc., in which the designs of the various items included are clearly described and illustrated. Particulars are included of the firm's cable-jointers' collapsible tents, of which, we understand, they have supplied a large number to all parts of the world.

## LEGAL INTELLIGENCE.

### "TUBE" VIBRATION.

Before Mr. Justice Lawrance and a special jury, the case of Stockton and others *v.* the Great Northern and City Electric Railway Company was commenced in the King's Bench Division on Tuesday.

**Mr. Rawlinson, K.C.**, explained that the plaintiffs were three daughters of the late Mr. O'Brien, who took the house No. 20, Highbury-crescent, in 1895, upon a 28 years' repairing lease, determinable at the end of 7 or 14 years. He built a stable, and altogether spent £1,300 on the house before taking possession. When the defendant company's tube was constructed, serious cracks in the wall occurred as the result, it is alleged, of subsidences of the soil. The damage continued to increase until the premises were declared unsafe at the end of 1903. Mr. O'Brien died in April, 1903, and his family were afterwards obliged to leave the house, which became uninhabitable. The premises were reinstated at a cost of £1,267, but the cracks soon reappeared. In addition to this the plaintiffs claimed £450, the cost of the forced removal, £225 for depreciation, £120 for drainage, and the amount of other losses.

**Mr. H. G. Deacon**, a civil engineer, of Westminster, deposed that the damage done to the house was such as could be caused only by subsidence from a tube railway or an earthquake.

**Mr. Lankester**, for the defendant company, suggested that all houses in this district were affected by a common general movement of the subsoil, wholly irrespective of the tube railway.

After expert testimony and evidence as to fact had been given, it was agreed that the jury should view the house before the hearing was resumed.

The company, it may be mentioned, had made an offer of £400.

### JANDUS ARC LAMP AND ELECTRIC COMPANY v. ARC LAMPS, LIMITED.

In delivering judgment, as reported in our last week's issue, Mr. Justice Kekewich granted an injunction, and refused to suspend its operation pending an appeal by the defendants. From this refusal the defendants appealed, alleging that the injunction would ruin their business, and that even if they should be ultimately successful in their appeal on the merits, they would be without any redress for the injury.

**The Court**, which consisted of Lord Justice Vaughan Williams and Lord Justice Stirling, made an order suspending the operation of the injunction pending the appeal, on the terms of the defendants being treated as licensees of the plaintiffs' patent. The defendants to undertake to keep an account of their sales, and the plaintiffs to undertake to return any moneys received by them from the defendants in the event of the defendants being successful in their appeal. The order to be without prejudice to any rights.

**Lord Justice Vaughan Williams** intimated that it would be right that a similar arrangement should be made in the event of an appeal to the House of Lords.

### TRAMS AND FOG.

In the Keighley County Court last week the Corporation were the defendants in an action brought by James Ellison Haggas, manufacturer, of Ingrow, who claimed £15. 7s. for damages to his brougham.

**Mr. Watson** explained that the plaintiff's wife and children were being driven from Ingrow to Keighley last November, and the coachman and plaintiff's wife were taking every precaution, on account of the dense fog, to avoid any accident. The coachman had the lamps lighted and was driving at a walking pace, while Mrs. Haggas was on the watch, with her head out of the carriage window. The lady heard a tramcar approaching in the rear, the driver clanging his bell, and after instructing the coachman to drive to the side of the roadway, called out to the car driver to stop. There appeared to be no notice taken of the cry, and the car crashed into the offside hind wheel of the brougham and caused the damages claimed for. He submitted that the car driver was clearly guilty of negligence in three respects: (1) that he did not keep a sufficient look out; (2) that he was travelling too fast, considering the dense fog; and (3) that although he admitted the next day to Mr. Haggas that he heard Mrs. Haggas call out, he did not comply with the request. The special defence was that the driver and conductor complied with all the ordinary requirements prescribed by the by-laws by running at a speed not exceeding nine miles an hour, that the driver continuously rang his bell and had the lamps of his car lighted, and that the collision occurred by reason of the plaintiff's coachman not causing his vehicle to be removed with reasonable dispatch so as not to obstruct the tramcar. Plaintiff's counsel admitted that the car might not be travelling more than three or four miles an hour, but contended that in the circumstances that rate was exceedingly rapid; and he further contended that even if the coachman was not using reasonable dispatch in getting out of the way, the Corporation were not entitled to run into the brougham.

After hearing evidence on both sides, **His Honour** said the case was a very interesting and somewhat difficult one. He knew of no authority as to how people were bound to behave in a fog. He did not see any evidence of neglect on the part of the plaintiff's coachman. When a person was in a fog he might, without any negligence of his own, lose his way. The coachman seemed to think that he was near the kerb, and if he thought it right to stop and find out he was perfectly justified. There would be no negligence in taking that care. Defendants contended that the coachman should have heard the bell, but Mrs. Haggas with her head out of the window did not hear it until

Digitized by Google

she spoke to the coachman. Was there negligence on the part of the driver? The man was driving carefully and in accordance with the wishes of his employers. It was said that the car must move, but he was not quite sure that that was true. It was very annoying when going by rail to find one's-self stopped for half an hour, but if the fog were bad enough that was the course taken by an engine driver. He thought that under the prevailing conditions the driver ought to have either called his conductor to walk slowly in front of him or some steps ought to have been taken so as to run the car without danger. He did not blame the driver, but in his judgment it was not right or lawful to drive through a fog at such a pace that he could not stop between the time of seeing a thing in front and running into it. He therefore gave a verdict for the plaintiff for the amount claimed.

Costs were given on the higher scale, and leave to appeal was granted.

# COMPANIES' MEETINGS AND REPORTS

## METROPOLITAN ELECTRIC SUPPLY.

The report for the year ending Dec. 31, 1904, states that the gross revenue for the year amounted to £306,540. 15s. 3d., as compared with £281,422. 5s. 8d. in 1903, being an increase of £25 118. 9s. 7d. The cost of generation, which in 1903 was £98,592. 10s. 8d., amounted in 1904 to £86,140. 14s. 1d., or a decrease of £12,451. 16s. 7d. The directors are of opinion that it would be advantageous to sub-divide the existing £10 ordinary shares into £5 shares and an extraordinary general meeting will be held immediately after the ordinary meeting to consider, and, if thought fit, to pass, resolutions authorising this to be done, and also to double the number of votes attaching to preference shares, in order to preserve the relative voting power between the ordinary and the preference shareholders. The balance at the credit of the revenue account, before providing for depreciation, is £176,837. 5s. 6d. The directors have set aside £20,000 as an addition to the depreciation and reserve fund, which, with the special additions referred to in paragraphs 4 and 5, now amounts to £216 355. 5s. 5d., carrying to the credit of the net revenue account the sum of £156,837. 5s. 6d. This sum, with the balance brought forward from last account and other receipts, makes a total of £170,982. 7s. 11d., of which, after deducting interest on debenture stocks and loans, dividend on preference shares and other charges, including interest paid to the Borough Council of St. Mary'ebone under the agreement referred to, there remains a balance of £108,157. 9s. 5d. An interim dividend of 9s. per share (being at the rate of 9 per cent. per annum) on the ordinary share capital, amounting to £45,000, was paid on Aug. 9, and the directors recommend that a further dividend of 11s. per share (being at the rate of 11 per cent. per annum) on such shares be now paid, making a total distribution for the year of 20s. per share, or 10 per cent. This will absorb a further sum of £55,000, and leave a balance of £8,157. 9s. 5d. to be carried forward to the next account. The total number of 8-c.p. lamps connected at the end of 1903 was 912,000, being an increase of 89,000 during the year. The present number connected is 930,000.

## NORTHERN COUNTIES ELECTRICITY SUPPLY.

The report for the year ending Dec. 31, to be presented at the fourth annual ordinary general meeting on the 10th inst., states that the work done shows a substantial increase on the previous year. The units sold totalled 986,873, against 344,781 for the previous year, and the gross receipts for current amounted to £12,280. 12s. 2d., against £4,979. 2s. 1d. In order to promote the more economical distribution of current and prevent the overlapping of interests in various areas in Northumberland, an arrangement has been made for the working and developing by the Newcastle upon-Tyne Electric Supply Company, Limited, of certain undertakings consisting of Whitley, Monkseaton, Earsdon, and Seghill. The revenue account, after an apportionment of charges between construction and revenue accounts, shows a credit balance for the year of £4,337. 11s. 5d. Adding balance from last year, £1,000. 12s. 4d., a sum of £5,388 3s. 9d. remains, which the directors recommend shall be disposed of thus: interim dividend already paid at the rate of 3 per cent. per annum, less income tax, £1,602. 2s. 10d.; final dividend at the same rate, less income tax, £1,649. 4s. 6d.; amount to reserve account, £1 500; preliminary expenses written off, £380; carrying forward £256. 16s. 5d. The money market being more favourable, it is proposed during the financial year now entered upon to offer the debentures, or a certain portion of them, to the shareholders at a fair rate of interest, as also the balance of the last issue of shares not yet taken up (14,537 in number).

## COUNTY OF LONDON ELECTRIC SUPPLY.

The report for the year ended Dec. 31, to be presented at the eleventh ordinary general meeting of the Company on the 16th inst., states that the revenue, including a balance from last account of £5 255. 7s., totals £90,534. From this have to be deducted (*a*) interest on the first and second debenture stock, £32,297. 6s. 2d.; (*b*) interim dividend on 30,000 6 per cent. preference shares for half-year ended June 30, 1904, less income tax, £8,568. 15s.; (*c*) interim dividend on 40,000 ordinary shares at 4 per cent. per annum for half-year ended June 30, 1904, less income tax, £7,616. 13s. 4d.; (*d*) amount carried to reserve for depreciation, repairs, renewals, etc., £19,150; leaving for further distribution £22,901. 15s. 8d. Out of this sum the directors now recommend: (*a*) that payment of the interim dividend on the 30,000 6 per cent. preference shares for the half-year ended June 30, 1904, less income tax, be confirmed; (*b*) that payment of the interim dividend on the 40,000 ordinary shares, at the rate of 4 per cent. per annum, for the half-year ended June 30, 1904, less income tax, be confirmed; (*c*) that a further dividend on the 30,000 6 per cent. preference shares for the half-year ended Dec. 31, 1904, less income tax, be declared; and (*d*) that a further dividend on the 40,000 ordinary shares for the half-year ended Dec. 31, 1904, at the rate of 5 per cent. per annum, less income tax, be declared, and that the said dividends be paid to all proprietors registered on March 3, 1905. This will absorb £18,050, and leave a balance of £4,851. 15s. 8d. to be carried forward.

## OXFORD ELECTRIC.

The report of this Company for 1904 shows a profit (including £830 brought forward from last year) of £11,803. After providing £2,050 for debenture and other interest, and writing off £608 on account of hire-purchase installations, the balance available for dividend is £9,144. The directors propose to pay a dividend at the rate of 7 per cent. per annum on the share capital ranking for dividend (whereof 2½ per cent. was paid in September last), adding £2,470 to reserve and renewal of plant account (which will then amount to £8,500), leaving £898 to be carried forward. It is estimated that at Dec. 31 last there was the equivalent of over 65,000 8-c.p. lamps connected to the mains. The number of Board of Trade units sold during 1904 was 13 per cent. larger than in the previous year. The new capital has been expended principally in erecting additional buildings for new machinery to meet the increased demand for current, in providing three transformers, and extending the supply mains in Banbury, Woodstock, Iffley and South Parks road, and St. Clement's and Walton streets.

## SOUTH LONDON ELECTRIC SUPPLY.

The report of this Company for 1904, to be submitted at the meeting to-day, states that, after making a full allowance for depreciation and preliminary expenses, the net balance is £21,884, from which must be deducted interest on borrowed capital, which absorbed £2,437, leaving a balance of £19,446. The directors now recommend a dividend at the rate of 4 per cent. on the ordinary shares, carrying forward £6,447. The number of lamps of 8 c.p. connected on Dec. 31, 1904, was 107,000, being an increase during the year of 15,098 lamps, while applications were in hand for a further 4,200 lamps. In accordance with the information given to the shareholders at the last annual meeting an issue of £50,000 debenture bonds was made in January of last year, the object being to pay off temporary loans and provide capital for necessary extension of mains and plant. The total number of units sold in 1904 was 9,205,342, an increase for the year of 4,399,861 units.

## HOVE ELECTRIC LIGHTING.

The report for the year ending Dec. 31, to be presented on the 16th inst., states that the net profits have increased, notwithstanding an indifferent season at Hove, from £11,215 in 1903 to £11,807 in 1904. With the balance brought forward from last year, and deducting debenture interest, other charges, and the interim dividend at the rate of 7 per cent. per annum, paid in October last, there remains a balance of £7,470. 18s. 1d. to the credit of net revenue account. The directors propose to place £3,000 to the reserve fund, which will thus be increased to £35,326. 12s., to declare a dividend, payable on April 15 next, at the rate of 10 per cent. per annum for the half-year on the paid-up share capital, making, with the interim dividend, 8½ per cent. for the year, and to carry the balance, £1,087. 1s. 7d., forward.

## W. T. HENLEY'S TELEGRAPH WORKS.

The twenty-sixth ordinary general meeting of this Company was held on Monday, Mr. Sydney Gedge presiding. Particulars of the account appeared in our last week's issue.

In moving the adoption of the report and accounts, the **Chairman** remarked that the Company was holding its own, partly by means of the new works and partly by giving as good work as they possibly could. He had hoped that the new works at Greenwich would be complete by this time, but various circumstances had delayed completion, and it would be six months before they were earning money.

The report was unanimously adopted, and a dividend of 15 per cent. sanctioned.

## BRITISH ELECTRIC TRANSFORMER.

The annual meeting of this Company was held on Monday, when the report, of which we gave particulars last week, was adopted.

## NOTTING HILL ELECTRIC.

The annual meeting of this Company was held on Tuesday at Winchester House, Sir William Crookes presiding. Particulars of the account appeared in our last week's issue.

The **Chairman** said that the rate of progress was being maintained this year, and they anticipated a normal increase of revenue of from £4,000 to £5,000.

The report was adopted.

## NEWCASTLE ELECTRIC SUPPLY.

The annual meeting of this Company was held last week, Dr. Merz presiding. Particulars of the report appeared in our issue of the 24th

Digitized by Google

ult. The report was adopted, and a dividend of 5 per cent. on the preference shares and 8 per cent. on the ordinary shares was declared. The provisional agreement for the purchase of the shares in the County of Durham Electric Power Distribution Company, Limited, was approved.

## NEW COMPANIES REGISTERED.

**Ferranti Limited.**—Capital, £130,000. Objects: to take over all or part of the undertaking, assets, and liabilities of Ferranti Limited, incorporated in 1901, to adopt an agreement between Ferranti Limited, of the first part, J. M. Henderson, the liquidator thereof, of the second part, and this company of the third part, to acquire any other electrical, mechanical, or sanitary engineering business, and to carry on the business of contractors for the erection of central stations for the supply of electricity for motive and other purposes, workers of such stations, constructors of railways, tramways, motorcars, of waterways and appliances appertaining thereto, telephone, telegraph, and electrical apparatus manufacturers, suppliers of electric power and electric generators, lamps, engines, etc. Registered office: Hollinwood, near Manchester.

**Electromobile Hiring Company, Limited.**—Capital, £8,000. Objects: to let out to hire, sell, and deal in electric and other motorcars and carriages, to carry on the business of automobile store and garage keepers, suppliers of electricity and other motive power, etc.

### Lien Registered.

**Langdon-Davies Motor Company, Limited.**—Lien registered Feb. 24, for £5,000 4½ per cent. debentures, issued in exchange for a like amount of debentures previously issued by the vendor company. No trustees. Charged on the undertaking and all the property, present and future, including the uncalled capital for the time being.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Salamanca.**—The Municipality requires tenders for public electric lighting. Tenders by March 14.

**Hoylake.**—The Council invite tenders for 250-kw. steam alternator, with piping, etc. Tenders by March 21.

**Hornsey.**—The Town Council require tenders for cables, meters, junction boxes, etc. Tenders by March 27.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**Cartagena.**—The Public Works Department, Madrid, require tenders for electrification of the local tramways.

**Leeds.**—The Corporation require tenders for the complete equipment of two sub-stations. Tenders by March 14.

**Sofia.**—The District Finance Commissioners require 15,000 insulators, elements for batteries, etc. Tenders by April 3.

**Barcelona.**—The Municipality require tenders for arc lighting of La barriada de San Gervasio de Cassolas. Tenders by March 15.

**Jawea (Province of Alicante, Spain).**—The Municipal Authorities require tenders for public electric lighting of the town. Tenders by March 12.

**Bucharest.**—The Post and Telegraph Department require tenders for 14 000 large, 8,000 medium, and 3,000 small insulators. Tenders by March 16.

**Fulham.**—The Borough Council invite tenders for the supply of electrical stores for year ending March 31, 1906. Tenders by 4 p.m. on March 15.

**Zurich.**—The Swiss Electricity Works (Schweizer Electricitätswerke) require tenders for 294,600 incandescent electric lamps. Tenders by March 15.

**Madrid.**—The Post and Telegraph Department, Carretas No. 10, require tenders for 32,000 zinc cylinders for Colland batteries. Tenders by March 15.

**Shoreditch.**—The Council invite tenders for their yearly contracts in the electricity works and other departments. Tenders by March 14. See advertisement in last issue.

**Bucharest.**—The Roumanian Government Railways require tenders for telegraph poles as follows: 2,000 7m. long, 2,000 8m. ditto, and 500 9m. ditto. Tenders by March 10.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Norwich.**—The Corporation require tenders for rubber-covered wires and accessories, underground cables, and incandescent lamps. Tenders by March 20. See advertisement.

**Plymouth.**—The Corporation invite tenders for the supply of electricity meters, transformers, and cables (paper insulated). Tenders by March 18. See advertisement in last issue.

**Johannesburg.**—The Corporation require tenders for 30 direct-current arc lamps with lanterns. Tenders by March 13 to Messrs. Mordey and Dawbarn, 82, Victoria-street, S.W.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Swansea.**—The Corporation invite tenders for the wiring and supply of sundry fittings for an installation of electric light at the new police and fire brigade station. Tenders by 12 noon on March 11.

**Madrid.**—The Post and Telegraph Department, Calle de Carretas 10, require tenders for telephone and telegraph apparatus, estimated at 35,337·50 pesetas. Tenders by March 10. This includes 50 Morse receivers.

**Keighley.**—The Electricity Committee invite tenders for the following plant: (Contract No. 9) one Lancashire boiler; (10) one 300-kw. direct-current steam dynamo, high-speed enclosed engine. Tenders by 10 a.m. on March 27.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station. Specification No. 619 may be obtained from the Government Railways Office, Brussels.

**Swindon.**—The Corporation invite tenders for annual supply of incandescent and Nernst lamps; cables; fuse boxes, service boxes, and feeder pillars; lubricating oils and grease; and direct-current meters. Tenders by March 21. See advertisement in last issue.

**Great Western Railway.**—The directors invite tenders for the supply, delivery, and erection of plant in connection with their electricity generating station at Park Royal and proposed sub-stations and distributing centres at various places. Tenders by March 13.

**Madrid.**—Der Compania Electrica Madrilena de Traccion propose to extend their electric tramways from the Barquillo-street to Olivide-place. The concession for the works will be dealt with by the Public Works Department, Madrid, April 2. Tenderers for same must deposit a guarantee of £96.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Stockport.**—The Corporation invite tenders for the team and manual labour and the supply of sand, drain boxes, and drains (only) in laying the permanent way of about 3½ miles of double line of tramway, including laying of special work in junctions and crossovers. Tenders by noon on 13th inst.

**Dublin.**—The Corporation invite tenders for the following contract, comprising supply and erection of two electric motors. Specifications may be seen at the Engineer's Office, City Hall, Dublin, or at the offices of the consulting engineer, Mr. G. Chatterton, 6, The Sanctuary, Westminster. Tenders by March 14.

**Edinburgh.**—The Corporation invite tenders for the annual supply of arc lamp carbons, cast-iron pavement and road boxes, electricity meters, house service fuse-boxes, earthenware trunking for laying electricity cables on the solid system, bitumen, and arc lamp globes. Tenders by March 13. See advertisement in last issue.

**Gloucester.**—The Electricity Supply Committee invite tenders for three Lancashire boilers and accessories, one 600-kw. generating set and accessories, electrically-driven surface-condensing plant to deal with 30,000lb. of steam per hour, steam, exhaust, feed, drain, condensing water, and sundry pipes, valves, etc., and an electrically-driven boiler feed pump, the whole bound up in one specification. Tenders by March 16. See advertisement in last issue.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**South Shields.**—The Electricity Supply Department invite tenders for the supply, delivery, and erection of the following plant: (Contract No. 67) one multitubular marine-type boiler, with chimney and mountings; (68) two medium-speed open-type vertical engines for two 550-kw. direct-current traction generators; (69) two 550-kw. direct-current traction generators; (70) traction switchboard; tramways department—(Contract No. 4) electric tramcars, complete with "Brill" trucks, for the Corporation. Copies of specifications, conditions, form of tender, also form of contract, can now be obtained from Mr. J. H. Cawthra, M.I.E.E., borough electrical engineer, South Shields, on payment of £2. 2s. for each contract, which sum will be returned on receipt of a bona fide tender for each contract. Tenders to Mr. J. Moore Hayton, town clerk, Court-buildings, South Shields, by noon on March 13.

### RESULTS OF TENDERS.

**Stepney.**—The Borough Council have accepted the tender of Jessop and Appleby Bros., Limited, Leicester, for an electrically-driven wall jib crane, at £150.

**London, S.W.**—The Chelsea Electricity Supply Company have accepted the tender of J. Greenwood, Limited, at £11,865, for erection of a new generating station, Manor-street, Chelsea.

**Newton Abbot (Devon).**—The Guardians have accepted the tender of Messrs. E. and E. Taylor, Alfreton-street, S.E., at £166, for supplying and fixing an electric lift, to carry a load of 10cwt., at the workhouse.

**East Ham.**—The Borough Council have accepted the tender of Dick, Kerr, and Co., Limited, Abchurch-yard, Cannon-street, E.C., for supply and delivery of five double-deck roof-covered tramcars, complete with the electrical equipment.

**Burslem.**—The Electric Lighting Committee have sealed the following contracts: Grant and Son, erection of electric lighting station,

Digitized by Google

destructor buildings, etc., at £3,745, and destructor chimney, at £850; Crompton and Co., switchboard, at £598, and arc lamps, at £443.

**Bournemouth.**—The Town Council have accepted the tender of J. G. White and Co., 22A, College-hill, Cannon-street, E.C., at £38 964, for Contract No. 1—(Section A) steel grooved girder rails, etc.; B) permanent-way construction and railbonding; (C) wood blocks and granite sett edging.

**Yarmouth.**—Messrs. Jno. Russell and Sons, Limited, of Crown Tube Works, Wednesbury, have secured the order for poles in connection with the Great Yarmouth tramways, through the British Electric Equipment Company, of 11, Queen Victoria-street, London, E.C., the length of route being four miles.

**Bridlington.**—The Corporation have accepted the following tenders for the installation of electric lighting (1) on the Prince's-parade, (2) in the Victoria Rooms and (3) in the town hall: (1) S. Dixon and Son, Limited, Boar-lane, Leeds, £346; (2) and (3) R. Bailey and Sons, Quay-road, Bridlington, £42. 2s. and £22.

**Colchester.**—The Town Council have accepted the tender of Davey, Paxman, and Co. (1) for Paxman's "Economic" steam boiler, 9ft. 9in. by 14ft. 6in., capable of evaporating 10 000lb. of water per hour, with pressure of 180lb. per square inch, at £605; and (2) for pipework for connecting up such boiler with the main steam range, at £155.

# BUSINESS NOTES.

## TRACTION.

**Reading.**—The Corporation have decided to adhere to the present hours of Sunday running.

**Yarmouth.**—A commencement has been made with the reconstruction of the Gorleston line.

**Halifax.**—The Corporation have decided to purchase two motor 'buses to serve the out districts.

**Ilford.**—The Urban District Council have decided to place £2,500 out of tramway profits to the credit of the general district fund.

**Brighton.**—The Corporation have refused consent to the application of the Sussex Motor Road Company for power to run a service of motor 'buses to Worthing.

**London Traffic Commission.**—The *Morning Leader* understands that the report of this commission will recommend a large extension of electric trams in the Metropolis.

**Newcastle.**—Extensions in Ridley-street and Scotswood-road are estimated to cost £5 549 with side poles, or £5,239 with centre poles, according to a report just issued by the Corporation.

**Aldershot and Farnborough.**—These two authorities have decided to apply for the recission of the light railway order on the ground that the company have not substantially proceeded with the work.

**Calcutta.**—It is reported that the extension to Alipore is being held up owing to the refusal of Government to allow the line to pass over Kalighat Bridge, or to contribute towards the widening of it.

**Nottingham.**—The Tramways Committee have promised to take into consideration the question of reducing fares, but Alderman Brownsward took the opportunity of deprecating constant applications for such concessions.

**West of Fife.**—It is reported that if the local authority insist upon their stipulations as to width of road and the sum to be annually paid by the promoters, the latter will abandon the scheme. A conference will probably be held.

**Bettws-y-coed.**—The Board of Trade have decided that a level crossing cannot safely be allowed in the district of Bettws-y-coed where the Snowdon and Bettws-y-coed light railway will pass over the Llugwy River near the Pontypair Fall. The Urban District Council are making alternative suggestions to the company.

**Wolverhampton.**—A breakdown on the Tettenhall-road section is reported to have occurred on the 1st inst. The supply of current failed, and subequently a fuse was blown in a feeder pillar. Telephonic communication with the officials at Cleveland-road resulted in the service being restored with all possible promptitude.

**Colchester.**—The Corporation have received a communication from the Board of Trade stating that the proposed position of the tramways in Military-road may be adopted, subject to the condition that there shall be everywhere a clearance of 15in. between the kerb and cars running on the lines. Provision has been made for this.

**Aberdare.**—Protests were made at a public meeting by the inhabitants of Hirwain against the Aberdare Council's tramway scheme. The chairman stated that the trams would not serve the district in question, and resolutions were carried urging the exemption of the inhabitants of Hirwain from contributing to the cost of the scheme.

**Stockport.**—The Corporation have decided to purchase 10 uncovered cars, with Brill trucks, interchangeable with the Brill trucks under the cars now in use, the car bodies to be obtained from the Brush Company and the equipment from the British Thomson-Houston Company. The electrification of the Edgeley route has been postponed in order that the question of motor 'buses may be considered.

**District Railway.**—The employés have held meetings to protest against the new rates of pay offered by the company, which are: motormen, 7d. per hour, rising to 8½d.; conductors, 5d., rising to 6d.; and gatemen, 4d., rising to 4½d. The directors are to be asked to receive a deputation. It is alleged by the employés that the new rates will mean weekly reductions of 13s. 6d., 4s., and 6s. 6d. respectively, calculated on the basis of a six-day week, with 10 hours per day.

**Tipton.**—At the monthly meeting of the Urban District Council it was reported that the tramways company had written declining to adopt ½d. fares between Great Bridge and Dudley Port and between Dudley Port and Sedgley-road. They also consider that the state of traffic did not warrant a 10 minutes' service, but the 15 minutes' service would be augmented when occasion demanded. The Council decided to ask the company to run a 10 minutes' service after 12 noon daily.

**Underground Electric Railways Co.**—At a special meeting of this company on Friday last, Mr. Charles T. Yerkes stated that the company, having sold £2,500,000 of debentures of the Baker-street and Waterloo Railway Company, the Great Northern, Piccadilly, and Brompton Railway Company, and the Charing Cross, Euston, and Hampstead Railway Company, the shareholders would not be asked to sanction the proposed increase of the borrowing powers of the Underground Company.

**Parliamentary Bills.**—The London County Council (Tramways) Bill, the Baker-street and Waterloo Railway Bill, the Charing Cross, Euston, and Hampstead Railway Bill, the Edgware and Hampstead Railway Bill, and the Great Northern, Piccadilly, and Brompton (No. 1) Bill were read a second time in the House of Commons on Tuesday. Mr. Whitmore's instruction to the committee on the London County Council (Tramways) Bill, to omit the proposed new lines over Westminster and Blackfriars Bridges, stood over.

**Darlington.**—The loss upon the tramways formed the main theme of discussion at a meeting of the Corporation last week. This is expected to be £1,900. Alderman Bartlett, the chairman of the Finance Committee, characterised the charge of 1¾d. per unit made by the electric department for the motive power for the tramways as unfair. It was a tacit understanding by the committee when the Corporation took over the horse tramways from the Imperial Tramways Company that the charge would not be more than 1½d. per unit.

**Glasgow.**—The Corporation Tramways (Consolidation) Bill came before the examiner at the House of Commons on Friday last. After the usual procedure, the Bill was found to comply with the Standing Orders, and was marked as such, but some time afterwards it was discovered that the assent of Partick had not been received. This made it necessary for the examiner to report that the Standing Orders had not been complied with. It will now rest with the Standing Orders Committee to say whether the Standing Orders should be dispensed with.

**Blagdon and Pensford.**—The following resolution was unanimously carried at two public meetings in the neighbourhood: "That this meeting is of opinion that the proposed light railway will greatly conduce to the prosperity and trade development of the district, and will also greatly assist the mining and agricultural and other industries, and be a great advantage to the public, and pledges itself to support the proposed railway by every means in its power." A memorial to the Light Railway Commissioners praying for the order was numerously signed.

**Swansea.**—At the meeting of the Tramway Committee the town clerk explained that the company wished a proviso inserted that if the Corporation made default in the supply of electricity, the company should not be held responsible. As regards licensing omnibuses, the Corporation were not at any time to allow any mechanical omnibus to ply for hire, and so compete with them. Eventually it was arranged to return the agreement to the company, leaving over certain points for further consideration. The Board of Trade are expected to inspect the new lines in about two weeks.

**Burton-on-Trent.**—At the meeting of the Tramways Committee the report of the electrical engineer of Jan. 27 last, on the subject of extending the capacity of the tramway generating plant to deal with the additional service of cars which the Burton and Ashby Light Railway call for, was read, and it was resolved that the electrical engineer obtain tenders for a 100 kw. continuous-current dynamo, to be coupled to the shafts of No. 1 alternator, together with the necessary switchboard and connections for the same. Messrs. Kincaid, Waller, Manville, and Dawson have in hand the preparation of the specifications for coupling up the two systems.

**Pontypridd.**—The completed portion of the system of electric tramways in course of construction by the Urban District Council was opened for traffic on Monday. The route now opened extends from Treforest, through Pontypridd to Coedpenmaen, Norton Bridge, and Cilfynydd. Three double-deck cars started soon after 11 o'clock from opposite the District Council offices. The journey was made without mishap, and as the gaily-decorated cars passed from point to point loud cheers were raised. Subsequently a luncheon was served at the New Inn Hotel, at which a large number of guests, the members of the Council, and others interested in the welfare of the town were present. The undertaking will cost, when completed, about £110,000.

**Cavehill and Whitewell.**—The report of this tramway company contains the following passage in reference to electrification: "The directors are glad to be able to state that a contract has been entered into between the company and the British Electric Traction Company, Limited, for the immediate reconstruction of the tramways for working by electric traction. It is provided that the work shall be completed by July 31 next, at which date it is intended that the system shall be ready for electrical running. In the event, however of any delay occurring from unforeseen causes the British Electric Traction Company have agreed to guarantee a dividend at the rate of 6 per cent. per annum on the existing issued shares of the company from July 31 next until the commencement of the working of the tramways by electric traction."

**Manchester.**—The Board of Trade have decided to adopt the recommendations of Colonel von Donop on the question of the distances at which the tramcars should be apart when running, and also as to the restriction which should be placed on the use of the lines in Portland-street, Peter-street, and John Dalton-street. This will allow the cars

Digitized by Google

in the central parts of the city to approach each other very closely. In the outer districts a distance of 25 yards is to be maintained between the cars. In Portland-street the Corporation proposed that between 9 a.m. and 7 p.m. cars should only run on one of the two sets of lines (south side) in cases of emergency, and in relieving traffic down adjacent streets, in which case there shall be a distance of 50 yards between following cars. This is agreed with by the Board of Trade, who think that, as a matter of fact, there need be no restriction as to running.

**Belfast.**—Messrs. White and Co. are experiencing great difficulties in the reconstruction of the system, owing to the action of the labourers, or a section of them. No sooner had a uniform rate of 6d. per hour been conceded than the men knocked off again. It appears the difficulty arose among the squad on Shankhill-road, and these, suddenly throwing down their tools, marched in a body along the whole route, ordering the others to cease work. The contractors invoked the aid of the constabulary, but the latter remained passive spectators of the open picketing which followed. Nearly a thousand men are idle in consequence. The Lord Mayor has been asked to negotiate for a settlement. The *Belfast News Letter* says the strike is the work of a handful of agitators, who will neither work themselves nor allow others to do so. Among the great bulk of the men themselves there is said to be a strong feeling of resentment against the originators of the strike. Sunday running has been confirmed.

**Llanelly.**—An extraordinary meeting of the Urban District Council was held last week to consider the opposition to the South Wales Electric Power Company's Bill. The chairman (Mr. D. James Davies) explained that the promoters of the Bill had an interview with representatives of the Council in November, when Mr. Graham Harris intimated that they were willing to step into the shoes of the British Insulated Wire Company, who had by agreement undertaken to carry out a system of electric light and traction in the district. They were then informed that the promoters would settle with the tramways company, and afterwards with the Council. Since they had seen it reported that they had purchased the tramway undertaking, but negotiations between the Council and the promoters of this Bill had not been concluded. Delay had occurred owing to Mr. Graham Harris going to Egypt, but before he went he asked their clerk to prepare an agreement, and after it had been thoroughly considered this had been submitted. They had not received any reply to it so far. He wished it to be distinctly understood that the relations between the parties were friendly. The Council had considered it expedient to put in a protective petition against the Bill, and the petition would be withdrawn upon an agreement being fixed up. He moved a formal resolution in line with the object of the meeting, and this was carried.

**Beckenham.**—It is reported that the scheme for the construction of tramways in Beckenham, for which the Urban District Council obtained an Act of Parliament in 1903, may be abandoned. The tramways were to have cost £28,000, and the scheme also involved street widenings to the amount of £62,550. By an agreement with the British Electric Traction Company, which was ratified by Parliament, the tramways when completed were to have been leased to the company, who were to pay the Council interest on the capital expenditure and also to repay the interest and sinking fund on the necessary loan. The company were also to cover the cost of necessary street widenings up to a total of £31,000, and at the end of 28 years to have handed the tramways in perfect working order over to the Council free of cost. When the ratepayers were originally appealed to they decided by a majority of 1,689 in favour of trams, but since then a number of members of the Council appear to have become enamoured of the motor 'bus, and it is stated that the Council now propose to cancel the agreement with the company for another, in which the company, when the tramways in the neighbouring district of Penge are ready, is to provide a service of motor 'buses. A report embodying these proposals has been received by the Council, but in view of the fact that the ratepayers had decided on a poll in favour of trams, it was decided that the full acceptance of the report should be held over for a fortnight.

**London County Council.**—Tuesday's agenda contained the following report and recommendation of the Highways Committee: "We have had under consideration the question of the steps to be taken to provide adequate accommodation for the repair and overhauling of the electric cars used on the Council's tramways. At the present time the cars are comparatively new, and the repairs which have been necessary have consequently not been of an extensive character, and these have had to be done at the particular depôts from which the cars are operated. We think, however, that, having regard to the great increase in the Council's tramways system, more adequate arrangements should be made at an early date for the repair and overhauling of the rolling-stock. In our opinion the present system of executing repairs at the several car-sheds does not properly meet the needs of the tramways undertaking. We consider that special repair shops should be provided in some central position where the cars could be periodically overhauled and where spare parts, which at present have to be obtained from the car manufacturers, could be made. It is probable that by direct production in the Council's own workshops, equipped and operated in a thoroughly economical and systematic manner, spare parts could be supplied at a cheaper rate and with greater dispatch than hitherto, a very important item in the maintenance expenditure of a tramways undertaking. In the first instance, buildings of sufficient capacity to meet present requirements might be erected, and they might subsequently be extended if required. We will report at a later date upon the proposal to erect new buildings specially for the purpose, as it will take some time to frame a comprehensive scheme that will meet the demands of the undertaking as it is likely to be developed in the future. In the meantime, however, it is of importance that more satisfactory provision than now exists should be made for the repair of cars, as an instalment of the larger scheme. A large car-shed, capable of accommodating nearly 300 electric cars, is being erected by the Council at New Cross-gate. This car-shed is in a comparatively central position as regards the Council's electric tramways, and we think that a portion of it should be temporarily equipped as a workshop for the repair of cars. For this purpose it will be necessary to provide plant, tools, and machinery, the cost of which is estimated at £5,000. If our proposal for the establishment of a special large central repair depôt, capable of dealing with the overhauling and maintenance for about 1,000 cars be carried into effect at some subsequent date, a considerable quantity of additional plant and equipment would be required. It would then be possible, however, to transfer from the New Cross car-shed the plant now proposed to be obtained, as this would form part of the complete equipment of the permanent repair depôt. By this means no loss would be incurred in the purchase of the plant required for the temporary equipment of the New Cross depôt. We propose, subject to the Council authorising the necessary expenditure for the purchase of the plant, machinery, tools, etc., to obtain prices from selected firms for the supply of the materials, the work being of a nature which makes that course desirable. We accordingly recommend 'that the estimate (No. 4,393) of £5,000, submitted by the Finance Committee, be approved; that expenditure, on capital account, not exceeding that amount be authorised for the provision of plant, machines, tools, etc., required for the equipment of a repair depôt at New Cross for the rolling-stock used on the London County Council tramways; that the Highways Committee be authorised to take all necessary steps for obtaining and installing the plant, etc., referred to; and that the seal of the Council be affixed to any necessary documents in connection with the matter.'" The receipts for the week ended Feb. 25 amounted to £12,091 as against £9,780 last year, and for the period from April 1 the total was £600,448 against £466,822.

## LIGHTING AND GENERAL.

**Loughborough.**—An electrical exhibition is to be held in April.

**Whitehaven.**—The consumption of electricity is increasing, and the receipts are correspondingly larger.

**Aspull.**—The District Council are conferring with the Lancashire Electric Power Company re the supplying of the township with energy.

**South London Electric Supply Co.**—A dividend has been declared of 4 per cent. on the ordinary shares for the year, carrying forward £6,446.

**Dewsbury.**—Application is to be made for sanction to a loan of £10,000 for additional plant and cable required at the electric light station.

**Bradford.**—The scheme for putting in additional fuse boxes is being proceeded with, and a special box has been designed for the purpose.

**Direct Spanish Telegraph Co.**—A dividend at the rate of 4 per cent., tax free, on the ordinary shares, for the half-year ended Dec. 31, is payable on April 1.

**Shetland Cable.**—Telegraphic communication between Shetland and the south, which was interrupted by the severe storm of Jan. 14, has now been restored.

**Tredegar.**—The District Council are negotiating with the Tredegar company with regard to the supply of electrical energy in bulk for public lighting purposes.

**Huntingdon.**—The Corporation have decided to consider the question of electric lighting, and have instructed Mr. Warden-Stevens, of Westminster, to advise on the matter.

**Hull Telephones.**—At the last meeting of the East Hull Social and Literary Society, Councillor J. Grindell, J.P., who presided, delivered an address on municipal telephones.

**Barnsley.**—The Town Council have completed the purchase from the Chatterley-Whitfield Collieries of land in Scotia-road for the refuse destructor and electric lighting station at £4,340.

**Change of Address.**—Mr. J. H. Rhodes, civil and consulting electrical engineer, M.I.C.E., has removed to 16, Park-lane, Leeds, and 22, Abingdon-street, Westminster, London, S.W.

**Bridlington.**—A letter from the Electricity Committee drawing the attention of the Guardians to the desirability of having the house lighted by electricity has been referred to the Visiting Committee.

**Southall-Norwood.**—The Urban District Council are opposing the Bills of the Metropolitan Electric Supply Company, Limited, and the Administrative County of London and District Electric Power Company.

**Darlington.**—The electrical engineer in his last report stated that to meet the increasing demand for current there would have to be extensions of the works, and the cost, if what he proposed were carried out, would be £2,000 to £3,000.

**London Gazette.**—The partnership between George Hubert Woods and Randal Beresford Slacke, carrying on business as electrical engineers at Blackburn under the style of G. H. Woods, Slacke, and Co., has been dissolved by mutual consent.

**Torquay.**—The post-card poll, referred to in our last issue, has resulted as follows: cards issued, 6,392; returned, 6,171. In favour of the scheme, 416; against, 5,069—majority against, 4,653. The number of inhabitants at the last census was 33,625.

**Tonbridge.**—The Electric Lighting Committee's last report shows that three applications for light, equivalent to 88 8-c.p. lamps, have been received during the month. The number of consumers to date totals 125, equivalent to 4,705 8-c.p. lamps.

**Thornhill.**—The Yorkshire Electric Power Company have made arrangements for a bulk supply with the Pudsey Corporation, the Mirfield Council, the Liversedge Council, and a supply is now available from the company's station at Thornhill.

Digitized by Google

**Lichfield.**—The Lichfield Gas Company and the Tamworth Gaslight and Coke Company have withdrawn their opposition to the passage through its committee stage in the House of Commons of the Shropshire and Worcestershire electric power scheme.

**Halifax.**—A report of the electrical engineer on the lighting mains and estimate of the cost of recommendations contained in the report, has been approved and adopted by the Electricity Committee. We understand that considerable expenditure is suggested.

**Liverpool.**—The Town Council have adopted a report of the consulting engineer as to charges for electrical energy. It appears that while a reduction is made in the cost per unit for tramway purposes, the ordinary consumer cannot obtain lower charges at present.

**North African Telephones.**—A new trunk line connecting Algiers with Constantine has just been completed. Arrangements are being organised for completing a grand trunk system of North African telephones by carrying the Oran line eastwards from Algiers as far as Tunis.

**Charing Cross and Strand Electricity Supply Co.**—From the 8th inst. the style and title of this corporation has been altered to the Charing Cross, West-end, and City Electricity Supply Company, Limited, in accordance with the special resolution of the corporation dated Feb. 3, 1905.

**Ripon.**—The City Council have adopted a resolution strongly urging adherence to the policy embodied in the Telegraphs (Telephones) Act, Act, 1899, which is based on the encouragement of municipalities and other local authorities and companies to provide local telephone services in connection with the Government trunk service.

**Johannesburg.**—It has been decided to replace all overhead telephone wires by underground wires. The cables will contain from 104 to 612 wires, and will be laid in 3½in. earthenware ducts, aggregating seven miles. The Village Main Reef Mine requires a three-phase generating plant with a capacity of 900 h.p. for hauling purposes.

**Blaydon.**—An amended proposal for the supply of electrical energy has been received by the Council from the County of Durham Electrical Power Distribution Company, Limited. The company have been asked for a price for street-lighting for 50-c.p. incandescent lamps, and also for a copy of their agreement with the Whickhaw Council.

**Melton Mowbray.**—An exhibition promoted by the Melton Mowbray Electric Light Company is being held in the corn exchange. The profits are to be devoted to the funds of the Leicester Infirmary. Numerous electrical appliances in lighting, heating, and power are on view, and various musical attractions are provided.

**Whitechapel.**—Messrs. R. W. Cunningham and Co. having asked the Guardians to permit them to advance the amount of their estimate for the installation of the electric light at Section No. 2 of the infirmary by 10 per cent., owing to the increase in the price of materials since the tender was sent in, the Guardians have resolved to hold the firm to their tender.

**Hampstead.**—At the last meeting of the Borough Council it was stated that the rate of 3s. 7d. in the £ (the same as for the half-year just ending) would have been increased by 1d. but for the fact that the Council has for the first time, included in the estimates a transfer of electric lighting profits in aid of the rates. This amounts to £2,000 this year, and to £2,060 for next year.

**French Cables.**—The Under-Secretary of Posts and Telegraphs is about to lay two new submarine cables, which have been voted by the French Government. One will be from Pontianak, the capital of the western division of Dutch Borneo, to Saigon in French Cochin China, and the other will be from Madagascar to the island of Réunion, which lies about 420 miles east of Madagascar.

**Carn Brea (Cornwall).**—An electrical exhibition is being held here. Among the varied purposes for which electricity is used as a motive power in this district the following may be of interest: air-compressor, forge and cupola blowing pulveriser, engineer's workshop, woodcutting, corn grinding and chaffcutting, butchers' machinery, bakers' machinery, lift, magnetic separator, pumping, etc., aggregating 240 h.p.

**York.**—Sufficient applications for current having been received, a cable is to be extended at an estimated cost of £250. Some of the street arc lamps are to be replaced by enclosed lamps, and additional lamps will be erected. It is also proposed to divide the lamps into series of two in lieu of 10 as at present, so that in case of the blowing of a fuse only two lamps will be affected instead of the whole series of 10 as heretofore.

**Hammersmith.**—The loan of £18 482 on account of the cost of installing the additional electrical machinery has been completed. Some additional land has been transferred to the electricity department. The premises of 19 additional consumers, representing a maximum of 370 8 c p. lamps, have been connected to the mains, and 35 consumers have been disconnected. The present number of consumers taking current from the mains is 1,555.

**Parliament.**—The following Bills have been read a second time: (1) in the House of Lords—Tyneside Tramways and Tramroads, Central Electric Supply, County of London Electric Supply Company, Mexborough and Swinton Tramways (Extension of Time), Oldham and Saddleworth District Tramways. (2) House of Commons—Andover Lighting and Power, Whitechapel and Bow Railway, and Weybridge and Walton-upon-Thames Electric Supply Bill.

**Colchester.**—The Council have passed a resolution strongly urging the Local Government Board to sanction the entire loan referred to in our last issue. The output of electricity in units in January, 1905, was 111,554, against 55,781 in the corresponding month of 1904 and 39,342 in 1903; the number of consumers at the end of January was 637, against 414 in 1904 and 334 in 1903; the total number of 8-c.p. lamps connected in 1905 is 30,601, against 25,174 in 1904 and 20,013 in 1903.

**Fans and Blowers.**—Messrs. John Gibbs and Son, ventilating and electrical engineers, Duke-street, Liverpool, are exhibiting at the Liverpool Motor Show their new "Peerless" blower, direct driven by their patent dust-proof motor, adaptable for blowing forges or removing dust from polishing wheels. They are also exhibiting a variety of electrically-driven ventilating fans and their patent quick-break safety starting switch, a most ingenious arrangement for minimising the possibility of accident with electric motors.

**Telegraph Revenue.**—The gross amount received during the last year by the Post Office in respect of telegrams, private wire rentals, special wire rentals, and other sources was £4 208,426. From this sum the amount paid to cable companies, £529,520. and telegram moneys refunded, £4,748, must be deducted, leaving £3 674,137. The amount expended by the telegraph section of the Post Office in salaries, rent, and other respects during the same period is £4,693,897, the balance of expenditure over receipts thus being £957,702.

**Sheffield.**—A committee, consisting of the Lord Mayor (Alderman Joseph Jonas), Aldermen W. E. Clegg and George Senior, and Councillors C. F. Bennett, A. Cattell, W. T. Gent, W. C. Fenton, J. C. Whiteley, J. W. Crowther, and C. R. Nowill, has been appointed to consider the means of giving a cheaper supply of electric current, to report on the advisability of closing one or more of the existing generating stations, as to the utilisation of surplus heat from the destructors for the production of current, and upon the question of electric supply generally.

**Gorleston.**—A cable has now been laid below the river bed between Yarmouth and Gorleston for electric lighting, traction, and power purposes generally. At first a ditch was dug to a depth of 7ft. by the new dredger "Sir Harry Bullard" of the Port and Haven Commissioners, which was hired by the Corporation, thus saving a large expenditure on excavating. The cable has been manufactured by the Callender Cable Company, and is a combination of three cables heavily armoured, the whole having a circumference of 9in. The cable starts from Yarmouth, and it comes ashore into a sub-station beside the steps up Ferry-hill. The sunken cable is to be covered up with soil to the depth of 7ft., and the Port and Haven Commissioners have issued a prohibition against vessels dropping their anchors in its vicinity.

**Aston.**—The Electricity Committee have resolved to abolish the two-rate system of charge, and in substitution thereof have adopted the following rate of charges for the supply of electrical energy for lighting purposes—viz., consumption under 300 units per quarter, 3½d. per unit; 300, but under 600, 3½d.; 600, but under 1,000, 3½d.; 1,000, but under 1,500, 3d.; 1,500, but under 2 000, 2½d.; 2 000 units and upwards, 2½d. Lighting accounts will be made payable quarterly, with a discount of 5 per cent. for payment within one month from date of issue of the account. The committee reserve to themselves the right to adopt the time-switch system for all consumers having an irregular load. They are about to purchase and fix a Worthington double-ram packed feed pump of approximately 3,000 gallons capacity, together with a cooling tank for the soft water, at a cost not exceeding £250. The committee having considered the question of supplying incandescent lamps to consumers, have authorised the electrical engineer to purchase 5 000 lamps for the purpose of retailing same as required, and, further, have authorised him to purchase Nernst lamps for the same purpose and maintain same if required.

**Stock Exchange.**—The Stock Exchange Committee have appointed March 15 special settling day for Havana Electricity Company's scrip (fully and partly paid) for £150,000 5 per cent. debentures, and have ordered the undermentioned securies to be quoted in the official list: City of Buenos Ayres Tramways Company's (1904) 243,708 shares of £5 each, fully paid, Nos. 1 to 241,671, 243,656 to 244,142, and 246,451 to 248 000; and £174,000 4 per cent. debenture stock, in lieu of the shares and debenture stock of the City of Buenos Ayres Tramways Company, Limited, now quoted; and Havana Electricity Company's scrip (partly paid) for £150,000 5 per cent. debentures. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to Henley's (W. T.) Telegraph Works Company's further issue of 5 000 ordinary shares of £5 each, fully paid, Nos. 35,001 to 40,000. The committee has also been asked to allow the following securities to be quoted in the official list: Bournemouth and Poole Electricity Supply Company's further issue of 4,500 ordinary shares of £10 each, fully paid, Nos. 22 501 to 27,000, and £80 000 4½ per cent. debenture stock; and Western Telegraph Company's further issue of £44,435 4 per cent. debenture stock.

**Pontypridd.**—An electric lighting and tramways scheme has just been completed. The cost on the electric lighting and generating station was about £55,000, and that of the tramways about £60,000, excluding the Rhondda section about to be constructed. The generating station is combined with a refuse destructor. The tramways are 3ft. 6in. gauge on the overhead system, and 3½ miles are equipped, while an extension of 1½ miles is under construction. The whole of the works were carried out by the consulting engineer to the Council, Mr. R. P. Wilson, of 66, Victoria-street, Westminster, Mr. W. S. King being his resident engineer. Since December last Mr. J. E. Teasdel, the Council's engineer and manager, has been occupied in organising the staff and in administrative work. The contractors were: overhead equipment, British Insulated and Helsby Cables, Prescot; track and pipe work, pumps, water-softener (Sinclair's), R. W. Blackwell and Co., London; underground cables, W. T. Henley and Co., London; buildings, Hughes and Stirling Bootle, Liverpool; engines, Coombe, Barbour, and Co., Belfast; dynamos, Greenwood and Batley; switchboard, Ferranti Limited; balancers, British Westinghouse Company; arc lamps, Johnson and Phillips; tramcars, British Thomson-Houston Company, Rugby (Brush Company, Loughborough, sub-contractors for car bodies).

Digitized by Google

**Bridgend.**—The report of the electricity department for the quarter ended Dec. 31 shows total receipts £311, as against £296 for the corresponding quarter of 1903. The number of units supplied by the power company was 37,430, as against 31,700, being made up as follows: public lighting, 19,692, against 15,361; private lighting, 16,692, against 15,439; sub-station, 598, against 400; unaccounted for, 448, against 50.

**Dartmouth Electrical Exhibition.**—The electrical exhibition held at the Subscription Rooms closed on Saturday evening last after a most successful run of four days, 2,801 persons having passed through the building between three o'clock on Wednesday afternoon and 10 p.m. on Saturday. The sum of £65. 6s. 11d., receipts from various causes, has been handed over to the Dartmouth and Kingswear Cottage Hospital. Mr. St. John Brown, of Newton Abbot, sang several songs at the exhibition last week.

**Telephone Operators' Union.**—The employés of the National Telephone Company are organising a union on similar lines to that among the Post Office workers in view of the transfer, six years hence, of the telephonic system to the Government. The movement originated in Liverpool, and at a largely attended meeting on the 4th inst. the objects and methods of the proposed association were discussed. It will be protective, and possess insurance features. Delegates were present from a number of towns.

**St. Andrews.**—An arrangement has been made under which the Town Council will erect four arc street lamps, and the electric supply company will supply current for keeping them—viz., four 10-ampere street arc lamps—burning for 1,500 hours at their full power, also do all repairs and maintenance and supply special cable to connect the lamps and between the lamps for the sum of £9. 1s. 3d. per lamp per annum, the Town Council to supply and own the complete arc lamp-posts. This offer is to hold good for five years.

**Anglo-Chinese Telegraph Convention.**—Mr. Berrington, director of the traffic branch of Indian telegraphs, has gone to Shanghai to assist in negotiations for the renewal of the Anglo-Chinese Telegraph Convention of 1894, the Chinese Government having notified under the terms of agreement a desire for the modification of the clauses referring to the maintenance of the line on the Chinese side of the Burmo-Yunnan frontier and the rates charged. The line in Yunnan beyond the Bhamo border is reported to be in want of repair.

**Southwark.**—The Borough Council have decided upon the following new scale of charges for current: Lighting—6d. for the first 1½ hours of average maximum demand and 1d. for any quantity afterwards, with discounts; flat rate, 4½d. per unit, with discounts. Power—3d. for the first hour of maximum demand and 1d. for any quantity afterwards, with discounts; flat rate, 2½d., with discounts. Discounts—2½ per cent. on quarterly bills of £50 or under, 5 per cent. on bills between £50 and £100, 7½ per cent. for £100 and £200, and 10 per cent. over £200.

**Grimsby.**—The Public Lighting Committee have decided that an extension of the electric plant is necessary to be prepared for the demand of 1907, and have left it to the engineer to prepare a scheme. The capacity of the plant at the present time is sufficient to deal with the equivalent of 46,000 8 c.p. lamps connected to the mains (after allowing for the public lighting). On Feb. 9 the equivalent of 42,000 8-c.p. lamps was connected, and, at the normal rate of increase, by December next the number connected will be about 43,000, and by December, 1906, 57,000. A temporary draughtsman is to be appointed.

**Football.**—On Saturday last the engineering works of the G.E.C., Witton, sent their football team to London to play Robertson Lamp Works, and after a somewhat exciting game Birmingham team ran out the winners by five to two. After the game they were invited by the Robertson Lamp Works to a tea provided by the president of the Robertson Lamp Works Club, Mr. C. Wilson, and after that a dance, which had been postponed from Wednesday. Mr. C. Wilson, in a speech, said that it was the first inter-works game that had ever taken place in the history of the G.E.C., and he hoped it would not be the last.

**Assessment of a Yorkshire Electric Light Works.**—Although the premises were still in the hands of the contractors, and would not be in working condition for some time to come, the new generating station of the Yorkshire Electric Power Company at Thornhill, near Dewsbury, was some time since assessed at a rateable value of £1,200. We understand that the company thereupon sought the advice of the Machinery Users' Association, with the result that their valuer, Mr. Humphreys-Davies, appeared before the Assessment Committee last week, and obtained a reduction of the rateable value from £1,200 to £10, until such time as the station should be profitably occupied.

**Wrexham.**—At the last meeting of the Electricity Supply Committee a letter was read from Mr. Ash, complaining that certain statements reported in the public Press referring to work done by him when an employé in the electricity department were inaccurate and calculated to do him harm. It was decided that Mr. Ash be informed that no blame attached to him in regard to the discharge of his duties up to the time when his voluntary resignation took effect, there being no ground for dissatisfaction as far as the committee had ascertained as to his capacity. The electrical engineer's report showed that in January there had been used for tramways and lighting, etc., 51,381 units as compared with 41,581 in January, 1904. Five new consumers had been connected.

**Metropolitan Asylums Board.**—Mr. A. C. Scovell presided on Saturday at the meeting of the Board held at the offices, Victoria-embankment. The Local Government Board wrote forwarding copies of an order authorising the execution of certain works for the purpose of lighting the Belmont Asylum by electricity and the provision of telephones and fire-alarms at a cost not exceeding the sum of £6,450 and the borrowing of that amount, which should be repaid in 10 years. It was resolved that application be made for sanction to the Managers inviting tenders for the installation of proposed systems of electric lighting, telephones, and fire-alarms at the Southern Hospital from nine selected firms, and to their entering into a contract or contracts for the execution of the necessary works, without in the first instance advertising for sealed tenders. It was stated that at the present moment the engineer-in-chief was not in a position to give a definite estimate of the cost of these works (full provision for which had been made in the expenditure sanctioned by the Local Government Board in connection with the erection of the hospital), but he anticipated the cost approximately at £9 000, of which the underground mains alone would account for about £3,000. It was decided that, subject to the assent of the Local Government Board, the plan of the proposed new boiler-house, destructor, and chimney shaft at the Eastern Hospital be approved, and that the Works Committee be instructed to take steps for the execution of the necessary work.

**Exeter.**—The City Council, in committee on Wednesday, considered the following interim report of the special committee appointed to consider the management of the electric light undertaking: "The special committee have elected Councillor Dunn chairman of the committee, and at three lengthened meetings have fully and carefully enquired into the matter referred to them. The committee are not yet prepared to report fully upon the general reference, but having regard to the special reference relative to the general competency of the chief officer, they beg leave to present this interim report. The committee, after careful enquiry, are fully satisfied with the competency of Mr. Munro as an electrical engineer, and are of opinion that the electrical engineer should have charge of all the works in connection with the electric light undertaking, including mains, and of the electrical equipment in connection with the tramways. Having regard to the extent of the works and the growth of the undertaking, the committee are of opinion that this is sufficient to fully occupy the time of the electrical engineer, and that some other arrangement should be made, by a readjustment of the present staff, with regard to the supervision and control of what may be called the mercantile side of the undertaking by an officer who should be in direct communication with the committee. The committee recommend that, having presented this report bearing testimony to the competency of Mr. Munro as an electrical engineer, that the matter should be again referred to them in order that they may report upon the general question of the management of the undertaking."

**Finchley.**—The Electricity Committee in their last report stated that they had had under consideration a report of the electrical engineer upon the progress of the electrical undertaking, and an estimate of the cost of the further extensions to buildings and plant which were necessary to cope with the increasing demand for current. They pointed out that the original loan of £35,000 provided for the supply of current to the equivalent of 10,000 8 c.p. lamps for private lighting and 600 8-c.p. lamps for street-lighting. The further loan of £16,600 made provision for the doubling of this output—*i.e.*, 20,000 8 c.p. lamps for private lighting and 1,200 8 c.p. lamps for street-lighting. There were connected, or applied for, at the present time the equivalent of 18,845 8 c.p. lamps for private lighting and 1,324 8-c.p. lamps for public lighting; and, in addition, 150 centre poles which were now being connected up. The engineer further estimated that during the current year at least the equivalent of a further 10,000 8 c.p. lamps would be applied for; additions and conversions of public street lamps to the number of 600 8 c.p. lamps would also be necessary, making in all a grand total of 31,370 8 c.p. lamps, or 10,170 8 c.p. lamps in excess of the capacity of the existing plant. The committee considered that arrangements should be made for extensions at once. Application is to be made for sanction to the borrowing of £23,500, made up as follows: machinery, £5,450; water supply, £2,180; buildings and sub-station, £6,750; mains, £5,370; service connections, £2,200; contingencies, office, and inspection expenses, and loan charges, £1 500. The committee have been authorised to invite tenders. The electrical engineer has reported that the work in connection with the centre-pole lighting was now in active progress, and would probably be completed in about a fortnight. Following on the recommendation adopted at the last meeting of the Council as to the acquisition of the undertaking of the Finchley Electric Light Company, the committee are, pending completion, supplying to the company in bulk.

**Annual Staff Dinners.**—The annual works dinner of the Croydon Corporation electricity works staff was held at the "Greyhound" on Feb. 24, the chief engineer, Mr. A. C. Cramb, being in the chair, supported by Mr. W. Burr, chief assistant engineer (vice chairman). A good programme of songs, recitations, and instrumental music was ably rendered by various members of the staff at the smoking concert which followed. An interesting little ceremony took place during the evening, the same being a presentation of a handsomely fitted travelling bag to Mr. C. W. Salt, who was leaving to take up a higher position at Bradford.—The first annual staff dinner of the Anchor Cable Company, Limited, Leigh, was held in the White Horse Hotel on Feb. 27, Mr. R. H. Harvey, the manager, being in the chair. After dinner songs were rendered by members of the staff an enjoyable evening being brought to a close with singing of "Auld Lang Syne" and the National Anthem.—The Fulham electricity undertaking held their second annual dinner at the King's Hall, Fulham, on the 3rd inst. Mr. A. J. Fuller, the chief engineer, took the chair, and about 70 members of the staff were present. A very enjoyable evening resulted, and it is interesting to notice that the whole of the musical programme was carried out by those in the Council's employ. The chief toast of the evening was "The Undertaking," proposed by the Chairman, who said it was a pleasure to him to be able to record a steady increase in the output and revenue, and a steady decrease in the cost of production, and these, he explained, had enabled the Council to sanction the reduction of the price for lighting current to 3½d. per unit with a small discount, which he was sure would induce further business. With reference to the destructor, the Chairman said that by reason of its efficiency it had become famous, and reminded them that approximately 35,000 tons of refuse per annum were destroyed

Digitized by Google

in Fulham at an average price which was at least 10d. per ton cheaper than the best results obtained elsewhere. In conclusion, he thanked the staff and all in any way connected with the department for the loyal support given and interest shown, and said that it was owing to the fact that all were pulling together to make the undertaking an even greater success that such a pleasing state of affairs could now be recorded. This toast was replied to by Mr. R. M Prescott (town clerk) and Mr. Councillor A. J. Warner (chairman of the Establishment Committee). Mr. G. T. Meek (superintendent of the destructor) proposed the toast of "The Chairman," which was enthusiastically received with musical honours.

## PROVISIONAL PATENTS, 1905

FEB. 27.

**4003. Improvements in dynamo-electric and electro-dynamic machinery.** James Grey Bell, 17, St. Ann's-square, Manchester.

**4040. Improvements in or relating to electric motors.** James Burke, 111, Hatton-garden, London. (Complete specification.)

**4041. Improvements in or relating to electric tools.** William Obed Duntley, 111, Hatton-garden, London. (Complete specification.)

**4062. Improvements in sparking plugs operating with magneto-electricity, for gas or oil engines.** Theodore Ferdinand Rene, 65, Chancery-lane, London. (Complete specification.)

**4075. Transformer for electrical metal-working apparatus.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (The Thomson Electric Welding Company, United States.) (Complete specification.)

**4076. Apparatus for welding and performing other metal-working operations by electricity.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (The Thomson Electric Welding Company, United States.) (Complete specification.)

**4089. Improved method of constructing electric accumulators and secondary batteries.** William Holloway Fellows and Edward Thomas Pickup, 173, Fleet-street, London.

**4097. Improvements in electromagnetic devices.** Hermann George Pape and Jacob Bender, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**4100 Improvements in electrolytic apparatus.** William Phillips Thompson, 322, High Holborn, London. (The Decker Manufacturing Company, United States.) (Complete specification.)

**4102. Improvements relating to electric tramways with conduit current supply.** Albert Newman Connett, 322, High Holborn, London.

FEB. 28.

**4109. Improvements in and connected with galvanic batteries.** Edward John Wade, 16, Elm-street, Gray's-inn-road, London.

**4122. Improvements in and relating to electrical switches for arc lamps and other circuits.** Sydney Hughes, 96, Buchanan-street, Glasgow.

**4127. Improvements in automatic electric warning signals for railways and the like.** Joseph Henry Hollyer, Rashwood House, Droitwich.

**4131. Improvement in telephone cables.** Alfred Whalley, Ashville, Helsby, near Warrington.

**4166. Telephone apparatus.** Robert Bines, 46, Lincoln's-inn-fields, London. (Complete specification.)

**4167. Telephone systems and apparatus.** Robert Bines, 45, Lincoln's-inn-fields, London. (Complete specification.)

**4168. Telephone transmitters.** Robert Bines, 46, Lincoln's-inn-fields, London. (Complete specification.)

MARCH 1.

**4233. Improvements in electric ignition devices for internal-combustion engines.** Frederick Millington and Albert Hugh Miller, 322, High Holborn, London.

**4237. Improvements in and relating to electric fuses.** Alfred Schwartz, 3, Brown-street, Market-street, Manchester.

**4249. Improvements in or connected with dynamos or electrical machinery, including their external circuits, with special reference to the regenerative system of electrical tramcar control.** Henry Winram Dickinson, 5, Salisbury-road, Wimbledon, London.

**4260. Improvements in the manufacture of electric cables.** Charles James Beaver and Ernest Alexander Claremont, 4, Bloomsbury-square, London.

**4273. Improvements in apparatus for automatic electric advertising and like purposes.** Guy Carey Fricker, 46, Lincoln's-inn-fields, London. (Complete specification.)

**4298. Improvements in or relating to joining belts, wire, or other ropes, cords, wires, electric cables or conductors, tyre wires, or the like, or for attaching terminals or other suitable end pieces thereto and means for affixing such attachments.** Arthur Henry Edwards, Birkbeck Bank-chambers, Chancery-lane, London.

**4307. Improvements in secondary electric batteries.** Pascal Marino, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**4303. Improvements in or relating to apparatus for obtaining constant voltage from dynamos working at varying speeds.** Maurice Eyquem, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, March 3, 1904, being date of application in France.) (Complete specification.)

**4305. Improvements in electric motor-starting rheostats and switches.** Henry Boultbee Brooks, 18, Buckingham-street, Strand, London.

MARCH 2.

**4313. Further improvements in apparatus for the automatic ignition of gas, gaseous mixtures, or the like by means of an electric current.** George Hill, The Grove, Ashton-on-Mersey. (Complete specification.)

**4315. Improvements in electric gas lighters.** George William Somerville, 68, Owen-street, Accrington.

**4321. Improvements in sparking plugs for electrically-fired internal-combustion engines.** Herbert Lewis, Wilfrid Hill, and Jack Whitfield, 24, Temple-row, Birmingham.

**4343. Improvements in and relating to arc lamps.** John Frederick Wakelin, William Bunn, and Charles Weston, 5, Tottenham-street, Tottenham Court-road, London.

**4354. Electric time switch.** Hilding Lübeck, 44, Grange-park, Ealing, London. (Date applied for under Patents Act, 1901, April 3, 1904, being date of application in Germany.) (Complete specification.)

**4362. Improvements relating to electric circuit systems.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (The Direct-Line General Telephone Company, United States.) (Complete specification.)

**4375. Improvements relating to dynamo-electric machines.** Robert Pohl, Felix Pohl, and the Phœnix Dynamo Manufacturing Company, Limited, 322, High Holborn, London.

**4379. Improvements in and relating to the supply and regulation of the electric energy employed in the operation of arc lamps used in searchlights and like apparatus.** The British Thomson-Houston Company, Limited, 83 Cannon-street, London (The General Electric Company, United States.)

**4384. Improvements in receivers for wireless telegraphy.** Guglielmo Marconi, John Ambrose Fleming, and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery-lane, London.

MARCH 3.

**4389. Improvements in and relating to magneto-electric generators for igniting the charge in internal-combustion engines and the like.** John Carlaw, 96, Buchanan-street, Glasgow.

**4395. Improvements in magnetic separators for ores and other materials.** Joseph Mansell Moss, 6, Bank-street, Manchester.

**4431. Automatic signals for loop-line signal arms and bells the whole worked by electric tramcar automatically.** George William Burden, 58, Uxbridge road, Hanwell, London.

**4456. Improvements in and connected with conduits for electric conductors or cables.** Thomas Easton Devonshire, 47, Lincoln's-inn-fields, London.

MARCH 4.

**4491. An improved drum for winding or coiling wire rope—copper, iron, or steel—electric cable, lead tube, hemp, or cotton rope.** David Muckley and Albert Payne, 112, Hood-lane, Little Sankey, Warrington.

**4497. Improvements in brakes for electrically-driven machinery.** Frederic Osmond Hunt, 19, Houndgate, Darlington.

**4513. Improvements in electric clocks or the like.** Frederick Augustus Chandler and Bshue Bonniksen, 18, Hertford-street, Coventry. (Complete specification.)

**4529. Improvements in the control of the electromotors on electric railway cars.** Francis Lydall, Queen Anne's-chambers, Broadway, Westminster, London.

**4540. Improved means for alternatively driving from a reciprocating engine and a rotary engine.** The Elektrizitäts Actien-Gesellschaft vormals W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, March 4, 1904, being date of application in Germany.) (Complete specification.)

**4541. Improvements in or relating to microtelephones.** Elektromilitära Aktiebolaget, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, March 8, 1904, being date of application in France. (Complete specification.)

**4544. An improved process for the electrolytic manufacture of metallic wire or strip.** Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

**4545. Improvements in the electrolytic production of metallic strip.** Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

**4567. Improvements relating to electrically-driven air-pumps.** Max Soblik, 18, Southampton-buildings, Chancery-lane, London.

Digitized by Google

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published March 23.*

1904.

**4937. Arc lamps.** Andrews and Manufacturing Electric Company, Limited.

**5064. Electrical and automatic working of signals, points, and crossing gates on railways.** Daboo.

**5294. Electric alarms.** Kiewert.

**5374. Electric gear for controlling lifts or hoists.** Björnstad.

**6690. Electrically-controlled lifts.** Bush.

**7428. Apparatus for moving electrically the points on electric tramways and railways.** Tierney and Malone.

**7660. Electric arc lamps.** Levis. (General Electric Company.)

**7676. Telephonic communication.** Lee.

**8064. Working of single lines of railway on the electric staff or other electric systems.** Jacobs.

**8922. Automatic electric switches and circuit breakers for controlling motors.** Haywood and Brounger.

**9660. Starting devices for electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**9841. Commutators for dynamo-electric machines.** British Thomson-Houston Company, Limited. (General Electric Company.)

**9842. Resistance units and methods of making same.** British Thomson-Houston Company, Limited. (General Electric Company.)

**9844. Vapour electric apparatus.** British Thomson-Houston Company, Limited. (General Electric Company.)

**9884. Controller for electric motors.** Soar and Joel.

**10019. Dynamo-electric machines.** British Thomson-Houston Company, Limited. (General Electric Company.)

**11604. Dynamo-electric machines.** Wilson. (Date applied for under International Convention, June 1, 1903.)

**11832. Vapour electric apparatus for rectifying alternating electric currents and other purposes.** von Recklinghausen.

**12976. Lining and insulating of chambers or cases carrying switches or fuses or both.** Ward and Goldstone.

**21995. Intercommunication telephone systems.** Birnbaum and White.

**22326. Controllers for electric motors.** Justice. (Voltage Controller Company.)

**23001. Automatic electric switches.** Scott.

**23182. Electric fire-alarms.** Hopkinson. (Date applied for under International Convention, April 15, 1904.)

**25378. Electric spark-gap apparatus for use with high-frequency currents, particularly adapted for therapeutic work.** Lake. (Electro-Radiation Company.)

**25382. Rotary spark-gap apparatus for use with high-frequency currents.** Lake. (Electro-Radiation Company).

**26098. Electric current-controlling systems.** Eastwood. (Date applied for under International Convention, June 4, 1904.)

**26917. Electrodes for arc lamps.** Whitney. (Date applied for under International Convention, Dec. 10, 1903.)

**27297. Means for lighting and extinguishing gas lamps by electricity.** Giorgi.

**27702. Method of winding for asynchronous electrical machines for producing a variable number of poles in the proportion of 1 : 2** Siemens Schuckert-Werke G. m. b. H. (Date applied for under International Convention, Feb. 13, 1904.)

**27842. Electric percussive tools.** Newton. (American Inventions Company.)

**28458. Incandescent electric lamp.** Howorth. (Guest and Hills.)

**28797. Apparatus for indicating the number of a telephone subscriber.** Andersen. (Date applied for under International Convention, March 30, 1904.)

**28824. Electric lighting arrangements for internal-combustion engines.** Renault. (Date applied for under International Convention, Feb. 2, 1904.)

## NOTES.

**New Publications.** — "Rateable Machinery," by G. Westall (London: Philip Allen and Co. 5s.). Nobody who is not a member of the legal profession would care about wading through the standard text-books on the subject of rateable machinery, and the author's concise review of the general principles regulating this matter, supplemented by abstracts of important cases, should prove of great utility.—Report No. 14 of the Engineering Standards Committee (price 2s. 6d.) The latest report of this committee deals with the standard specification for structural steel for marine boilers, which the main committee approved after the subject had been carefully investigated by a sub-committee.

**Cantor Lectures.**—On Monday last Mr. Herbert Laws Webb delivered the first of a series of four lectures on telephony at the Society of Arts. The importance of this industry, which has grown up within the past quarter of a century or so, was shown by the fact that over 5,000,000 telephones were in use, and a quarter of a million of men employed. The lecturer briefly described the acoustical requirements for telephony, and showed the evolution of the apparatus employed, how Reiss had made his investigations with interrupted currents, and how necessary for clear speaking were undulating currents. The names of Elisha Gray, Graham Bell, Edison, Hughes, Hunning, Blake, and others were mentioned, and their work in the development of the apparatus described. The voice of the lecturer was greatly assisted by screen illustrations, and excepting that, as in all these cases, the matter is too much for the time, the audience must have been edified at the clear and simple way in which the lecturer treated his subject.

**Electrification on the Brighton Line.**—One of the features in connection with the electrification of the Brighton Company's suburban service will be the type of car. As most of the traffic will probably be terminal, and in order to utilise the full carrying capacity of the line, it will be essential to reduce stoppages at the termini to a minimum. Besides adopting the multiple-unit system, end gangways on the cars will be substituted by sliding side doors along the whole length of the train, to facilitate the discharge of passengers. This arrangement is similar to that introduced on the Illinois Central Railway described in our issue of May 20 last. Instead of a centre aisle there will be a gangway down each side of the seats. This design entails a certain loss in seating accommodation, but it is stated that a later contrivance enables the seats to slide, so that the gangway on the other side from the platform can be utilised, the arrangement being reversed for the return journey. The doors will be operated by compressed-air motors, power being supplied by the Westinghouse brake reservoirs, and it will also be possible for passengers to open them independently.

**Glasgow Wiring Rules.**—The new issue of wiring rules by the Glasgow Corporation Electricity Department reflects the views on the earthing question expressed by Mr. W. W. Lackie in his paper before the Local Section of the Institution of Electrical Engineers. Thus the principal alteration in the new wiring rules is that dealing with the bonding and earthing of metal-sheathed conductors and metal tubes and conduits. The Corporation now most distinctly insist that all metal tubes into which insulated electric light wires are pulled must be connected together by means of properly screwed sleeves or couplings, or securely soldered together so as to form a permanently continuous conductor from end to end of the system. Also, where iron pipes are used for protecting insulated electric conductors, it is necessary always to keep these iron pipes clear of gas-pipes by means of a distance-piece, and special attention is drawn to the fact that this distance-piece is always fixed securely in position. There is a slight addition to the rule concerning the insulation of paper and jute-covered cables, and the undue use of flexible on installations is discouraged. Bare terminals on motors and accessories connected therewith are also prohibited, and these must be covered in some way.

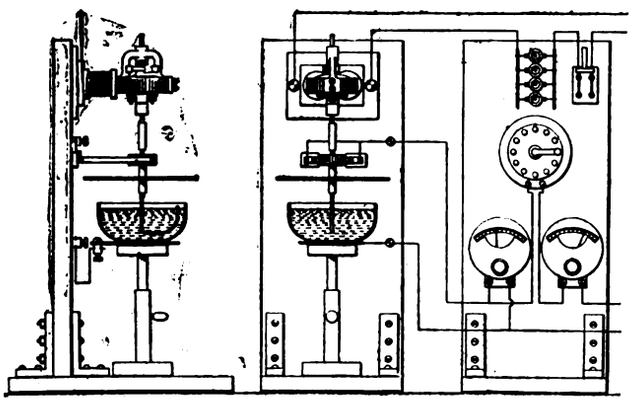
**Royal Institution.**—Prof. J. J. Thomson delivered on Saturday the first of three lectures upon "The Electrical Properties of Radioactive Substances." Discussing the behaviour of a gas that was being ionised at a definite rate, the lecturer showed that the number of electrified particles could not increase indefinitely, because simultaneously with their production a process of destruction was going on. If a gas while being ionised was exposed to an electric field, some of the ions would be removed by being driven against the plates connected with the battery, and the greater the force the larger the number that would be so treated. The number of ions produced by the radioactive substance in a given time was not, however, indefinitely large, and therefore the conducting power of the gas would reach a limit beyond which it would be unaffected by any increase in the strength of the electric field. The current passing would thus reach a constant value, known as the saturation current. This current was most important in the study of radioactive substances, because it represented a perfectly definite quantity, and its measurement constituted the most delicate method of detecting a radioactive substance. On Tuesday next, March 21, at five o'clock, Prof. W. E. Dalby will deliver the first of two lectures at the Royal Institution on "Vibration Problems in Engineering"; and on Thursday, March 23, at the same hour, Prof. R. Meldola will begin a course of two lectures on "Synthetic Chemistry" (experimental). The Friday evening discourse on March 24 will be delivered by Sir Oliver Lodge, the subject being "A Pertinacious Current," and that on March 31, by Prof. J. Wright, will be entitled "The Scientific Study of Dialects."

**American Electro-Chemical Society.**—The annual meeting of this institution is to be held at Boston, Mass., on April 25, 26, and 27, and we give below the preliminary list of papers that has been announced. A plentiful supply of current for demonstrations and exhibition purposes will be available While limitations of space will not permit of a general invitation to manufacturers to display their products, the committee offer to make all possible arrangements for such exhibits on application being made to the secretary-treasurer, Prof. H. P. Talbot, Massachusetts Institute of Technology. The headquarters will be at the Hotel Lenox. The papers are as follows: "Microstructure of Silicon and its Alloys," by Mr. A. B. Albro; "The Migration and Coagulation of Colloidal Suspensions," by Mr. J. C. Blake; "Chromium," by Mr. H. R. Carveth; "Treating Low-Grade Ore and Tailings by Electrolysis," by Mr. Ernst Fahrig; "Billitzer's Method of Determining Absolute Potentials," by Mr. H. M. Goodwin; "An Optical Method of Observing Diffusion in an Electrolyte," by Mr. C. Hambeuchen; "Removing Solvents during Electrolysis," by Mr. Carl Hering; "A Low-Voltage Standard Cell," by Mr. G. A. Hulett; "Osmosis," by Mr. L. Kahlenberg; "Some Experiments with the Reduction of Titaniferous Ores into Steel and Titanate of Iron," by Mr. A. Lodyguine; "Experiments with the Reduction of Different Oxides of Lead by Electric Current," by Mr. A. Lodyguine; "Some Results of Experiments with the Electro-deposition of Metals on Aluminium,"

Digitized by Google

by Mr. A. Lodyguine; "The Interdependence of Atomic Weights and Electro-chemical Equivalents," by Mr. A. Reuterdahl; "Conduction in Electrolytes," by Mr. J. W. Richards; "Water Powers of the Canadian Hinterland," by Mr. C. C. Richardson; "Electro-deposition of Silver," by Mr. R. C. Snowden; "Adherence of Nickel to Nickel," by Mr. R. C. Snowden; and "A New Diaphragm Cell," by Mr. C. P. Townsend. Papers are expected from Messrs. W. D. Bancroft, C. F. Burgess, A. J. Rossi, and others.

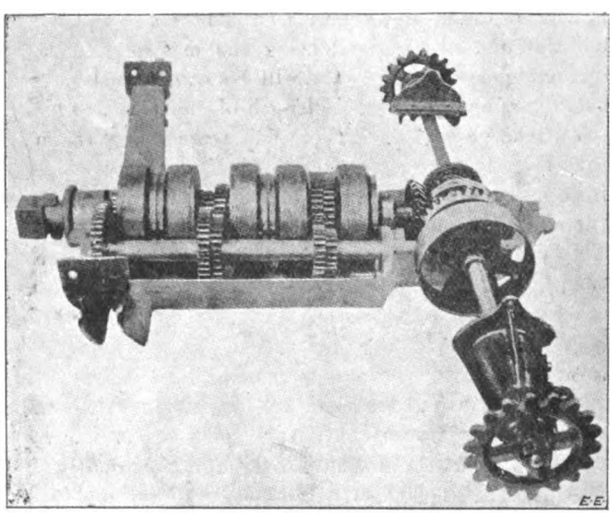
**Rotating Anode for Rapid Electro-Analysis.**—It has been found by Mr. N. M. Hopkins that by using a rotating anode for the electro-analysis of metals they can be completely precipitated in a few minutes, whereas with a stationary anode it is necessary to employ such feeble electric currents that several hours are occupied in the



process. He gives a description of the apparatus in the *Scientific American*. The outfit is exceedingly simple, as will be seen from the accompanying diagram. It consists of a vertical board firmly bolted to a heavy base by angle irons, and supporting an electric motor mounted with its shaft in a vertical position. Although this motor has practically no work to do in rotating the platinum wire in the solution, the use of a very small motor is to be deprecated, as it cannot be operated in connection with a lighting circuit, even by using a lamp bank. Directly under the commutator, upon which copper or preferably carbon brushes feed, is a large metal disc to prevent any minute particles from falling into the solution. The platinum dish should rest upon a sheet of platinum supported on an adjustable stand, in order that the dish may be quickly lowered to remove the anode. The necessary instruments for maintaining the proper electrical conditions are shown in the extreme right of the illustration. The author is contributing a series of articles upon "Experimental Electro-chemistry," appearing bi-weekly in the *Scientific American Supplement*, where a more detailed account of electro-analysis is given, and where those interested in this subject will find certain recent laboratory data. It may be stated, however, that the effect of the rotating anode is to maintain a homogeneous electrolyte by preventing concentrating changes due to differential ion velocity.

**Faraday Society.**—The first annual general meeting of this institution was held on the 6th inst., the treasurer, Dr. F. Mollwo Perkin, presiding. Allusion was made in the report to the enthusiastic efforts of Mr. Sherard Cowper-Coles, to which the formation of the society was largely due. At his suggestion an informal meeting was held, at which a provisional committee, consisting of Mr. J. Swinburne, Mr. W. R. Cooper, Mr. Cowper-Coles, Dr. F. G. Dorman, Dr. Perkin, and Mr. H. V. Simpson, the latter of whom has since been succeeded as secretary by Mr. F. S. Spiers, was appointed. Having extensively circularised the profession, it was decided to create an organisation for the study of electro-chemistry and kindred subjects under the title of the Faraday Society. The arrangement by which an exchange is made with the American Electro-chemical Society of the literature issued by the respective bodies has given mutual satisfaction. There is, however, one feature in the history of the society which the council cannot look back upon with gratification, the membership roll having remained practically stationary. We trust there will be a substantial response to the reiterated appeal of Sir Joseph Swan for wider support, in order to increase the range of efficiency of the society's operations. The officers for the ensuing year were elected as follows: president—Lord Kelvin, O.M., G.C.V.O., F.R.S.; past-president—Sir Joseph Wilson Swan, F.R.S.; vice-presidents—Prof. A. Crum-Brown, F.R.S.; Sir William Huggins, K.C.B., P.R.S.; Sir Oliver Lodge, F.R.S.; Ludwig Mond, F.R.S.; Lord Rayleigh, O.M., F.R.S.; Alexander Siemens, Pres.I.E.E; James Swinburne, M.I.C.E.; treasurer—Dr. F. Mollwo Perkin; council—George Beilby, Bertram Blount, W. R. Cooper, Sherard Cowper-Coles, Prof. A. K. Huntington, Dr. R. A. Lehfeldt, W. Murray Morrison, M.I.C.E., Dr. W. S. Squire, Dr. O. J. Steinhart, Prof. Ernest Wilson. The meeting concluded with votes of thanks to the retiring president (Sir Joseph Swan), the honorary auditors (Messrs. L. Gaster and T. M. Lowry), and to the Institution of Electrical Engineers for the free use of their library for the monthly meetings.

**Magnetic Change-Speed Gear.**—Suggestions have been made from time to time for the substitution of the ordinary cone friction clutch in motorcars by magnetic clutches, and the Société la Magnétie, of Paris, has designed such an arrangement, which is described in the *Car*. The change-speed lever is dispensed with, the speed being regulated by an electric controller, which replaces the sliding gear. The device consists of two steel plates for each speed, the plates being located opposite each other, with a short interval between them. One of them is hollowed out to contain the coil through which it is magnetised by a dynamo or accumulators.



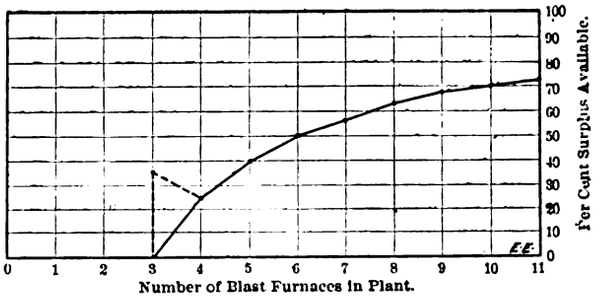
This causes attraction between the plates, which adhere to each other. The pinions remain in gear, but are free to revolve round the first-speed shaft, except when the two plates corresponding to each speed are attracted towards each other. The first-speed pinion is attached to one of the plates, the other plate being attached to the first-speed shaft, so that when the two plates adhere to each other the first-speed pinion corresponding to them becomes solid to the first-speed shaft and drives the second-speed shaft, which, in turn, actuates the differential gear. This method has been found to greatly facilitate changes of speed, which

Digitized by Google

are accomplished without shock or noise. It is stated that a change can be made from the third speed to the reverse motion without any difficulty or danger, the reverse motion acting in this case as a brake until the car has stopped and reversed. If this device carries out its early promise, it will materially assist in disposing of the trouble with the cone friction clutches.

**Electric Lifting Machinery.**—Mr. Edward C. R. Marks read before the Birmingham and District Electric Club on the 11th inst. an interesting paper on this subject, in which he has specialised. The lecture was illustrated by a large number of lantern slides showing various types of electrically-driven lifting gear. Referring to overhead travelling cranes, the author traced the development of electrical driving from the single-motor crane exhibited at the Paris Exhibition in 1889 to the three-motor crane, which may be looked upon as standard practice nowadays. Further on in the paper, however, a description was given of a heavy crane in which four motors were used, there being two connected with the lifting gearing—*i.e.*, a small motor for light loads and a large one for heavy load. Referring to the gearing for such cranes, the author, while alluding to the simplicity and compactness of worm gearing, preferred under ordinary conditions spur gearing with machine-cut teeth as being more satisfactory. In very heavy cranes, however, the spur wheel on the parallel shaft is frequently made with machine-moulded teeth. When dealing with the question of the electric motors, the conclusions of Mr. A. P. Head, given at the engineering conference held in London in 1903, were quoted to the following effect: "The most suitable form of electric energy is continuous current at 220 to 500 volts. This is superior to alternating current on account of the greater starting torque and acceleration given by the former. The operations of a crane involve a rapid succession of startings and stoppings; continuous current occupies an unimportant fraction of the time, and loads are very variable. Alternating-current motors, while efficient at full load, can have a strong starting torque only at the expense of efficiency. Continuous current, on the other hand, admits of easier regulation of motors, is cheaper in wiring, and can be stored in batteries to equalise a variable load. Series-wound motors, which automatically run faster with lighter loads, should be used if they are coupled permanently to the gearing. They should withstand 100 per cent. overloading for short periods, and much higher loads momentarily without damage, which conditions are fulfilled by the ordinary tramway type. Where motors run continuously, with clutch connections to the gearing, they should be shunt wound." Mr. Marks seems to prefer the lower voltage of 220 for such work, owing to the danger from shocks when working at 500 volts. At the conclusion of the paper some interesting information was given of a large quantity of electric lifting apparatus recently manufactured by various manufacturers throughout the country. Concerning these, some useful figures were collected of the overall efficiency of overhead cranes, passenger lifts, jib cranes, etc. These efficiencies varied from about 55 per cent. up to over 80 per cent., and in one particular instance an electric winch is described, of which the efficiency is as high as 84·6 per cent. at full load and 83·1 per cent. at half-load. The question of brakes on lifting gear was also thoroughly gone into by the author, who spoke highly of the electrically-controlled band brake, such as is met with very frequently. Such a brake designed to hold up the load if the current is interrupted is an invaluable feature in electrically-driven apparatus. This electric brake is, however, frequently supplemented by a mechanically-operated one, especially in the case of jib cranes, when the barrel is not always in gear with the motor. The illustrations made the lecture a most interesting one, and it was highly appreciated by the members of the club.

**Power Gas for Blast Furnaces.**—There appears in the March number of the *Electro chemical and Metallurgical Industry* of New York an interesting article by Mr. F. du P. Thomson on the commercial possibilities of blast-furnace gas for the development of electric power. The author deplores the fact that until recently all the pioneering work in this field has been done on this side of the Atlantic. He attributes the inactivity of American engineers to the fact that they have had for the last four years an enormous volume of remunerative business to deal with, so that any money available was worth more as working capital than if used in providing more economical means of operation. The author looks into the question of how much power there would be available in connection with a given number of blast furnaces, assuming the blowing engines for these furnaces to be themselves worked by means of gas-engines. In reference to guarding against any reduction in the output when one or two furnaces are under repair, he finds that the surplus gas available increases rapidly with the number of blast furnaces in the plant. This is represented in curve form in the accompanying figure. After

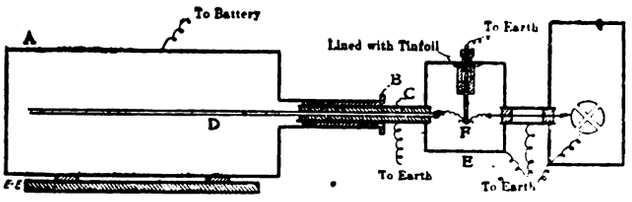


dealing with the practical details of purifying the gas for use in gas-engines, figures are given to show the advantage of using such engines in connection with the blast furnaces themselves. The author then goes into statistics as to the cost of electrical energy obtained from blast-furnace gas. Such figures have been given before in our columns, and have been supplemented by results obtained in actual practice. It is interesting, however, to quote Mr. Thomson's net results, which are as follows: With a plant consisting of four 1,000-kw. units, of which one is to be used as spare, working with a load factor of 50 per cent. over 24 hours a day, he calculates that the total cost per unit will be about ½d. In this cost he allows 5 per cent. as interest and 8 per cent. for sinking fund, and assumes that each of the units is capable of working up to 50 per cent. overload. The cost per kilowatt-year of station capacity is then about £9, which, with the load factor in question, would allow of electric power being used over a considerable area. His other calculation gives for much the same plant, worked with an 80 per cent. load factor, but without any overload capacity, much lower figures. In this case he assumes that the same units will be rated as of 1,500 kw. capacity, and the cost per unit comes out as low as 0·219d. In these calculations no allowance is made for the gas taken from the blast furnaces, which at the present time is running to waste. The author estimates that the return to the blast-furnace owner if the power were utilised would be equivalent to 1s. 3d. per ton of iron produced in the first calculation, or to about 3s. per ton with an 80 per cent. load factor. The editor of our contemporary supplements these calculations by an interesting one which shows that the output of pig iron in the United States for 1904 was 16½ million tons. On Mr.

Digitized by Google

Thomson's figures the surplus gas from the furnaces producing this iron should develop nearly 900,000 h.p., which is almost one-half of the capacity of the electric central stations in the United States as given in the census report of 1902. The point for electrical engineers to remember is that while cheap power can be produced by the waste gases from blast furnaces, it is only by high-voltage transmission that this power can be conveyed to consumers in the surrounding areas. There is, undoubtedly, a large field in this country for this class of installation, but a substantial reduction in the prime cost of gas engines would help matters.

**Sensitive Quadrant Electrometers.**—Prof. J. C. McLennan, of the University of Toronto, recently delivered an address on the use of sensitive quadrant electrometers, an account of which appears in the *Electrical World*. Prof. McLennan stated that in making measurements upon the conductivity of a gas by means of a highly sensitive electrometer, such as the Dolezeleck type of instrument, considerable delay and inconvenience was frequently experienced on account of the disturbance imparted to the needle by simply breaking the earth connection to the free quadrants. Such disturbances are in great measure due to electrostatic effects caused by the approach of the observer's body, or even his hand, in the process of breaking the earth connection; and in order to avoid them, it has become the practice to surround the electrometer and the testing apparatus with earth-connected metallic screens, and also to make and break the earth connection to the quadrant by keys of a special form, which the observer can operate from a distance by means of strings or other connections. In using different keys, however, Prof. McLennan found that, with electrometers of high sensitiveness, small though relatively important initial disturbances still existed, and arose from a variation in the capacity of the measuring system caused by the action of the key itself when the earth connection was broken. In order to overcome this defect, it was only necessary to take special precautions in the construction of the key to reduce this variation in capacity to a minimum. The general arrangement of apparatus adopted in measuring the conductivity of a gas is shown in the accompanying diagram. The receiver, A, which contains the



gas whose conductivity is to be measured, rests on insulating supports, and is connected to a battery of small storage cells. It is provided with an ebonite plug, B, which carries an earth-connected brass tube, C. This tube in turn also carries a second ebonite plug, which supports the exploring electrode, D. The tube, C, and the electrode, D, penetrate a small wooden box, E, lined with tinfoil, also connected to earth, and connection is made at F with the contact key of special form. The electrometer is supported in a box of wood lined with tinfoil connected to earth, and its free quadrants are connected to the key, F, by a wire supported by ebonite plugs in an earth-connected brass tube, which at one end penetrates the box containing the key and at the other that containing the electrometer. The key of special form consists of two brass parts, as shown in the accompanying diagram, held by means of an ebonite support with their parallel faces as close together as possible without touching. The whole is supported against the tinfoil lining on the top of the box by a nut, which keeps the upper brass part always connected to earth. Both of the brass parts are pierced by a small opening less than a millimetre in diameter, and the earth connection to the quadrants is made or broken by inserting or withdrawing a fine rigid steel wire, which moves freely through this opening. It will be seen that with this device the earth connection can be broken with practically no variation in the capacity of the measuring system. By using this key and making the arrangements described above for screening off electrostatic induction, it has been found quite immaterial whether the earth connection is broken by hand or by means of strings operated from a distance. In either case the process is not followed by any disturbance of the needle. All initial oscillations are stated to be entirely eliminated, and the needle, although starting from rest at the moment the contact is broken, almost immediately assumes a steady rate, and its motion may be taken as a measure of the conductivity of the gas at the instant the quadrants are freed.

**Steel Cars on the New York Subway.**—In the equipment of the new steel cars for the New York Subway special attention has been paid to the design and protection of the car wiring, which is described in the *Street Railway Journal*. The adoption of car bodies employing steel exclusively, not only for framing, but also flooring, made it impossible to support the wiring beneath the floor by any of the usual methods. As it was desired to keep all the wiring and other equipment as far as practicable beneath the car body, it was necessary to construct mechanical supports for the large amount of wiring required and for the 12 rheostatic steps, and in this connection the following considerations had to be studied: safety from fire, which prohibited the use of wood; protection of wiring against abrasion; the use of insulation having an ample margin of safety with reference to the potential employed; and the reduction of the insulation to a minimum, the need of the last being emphasised by the fact that though the risk from any possible burning of wire insulation was negligible, there remained the chance of a panic through smoke from burning insulation. An insulation of very high grade and moderate thickness was therefore selected for the wiring, the insulation of conductors of the larger sizes being $\frac{1}{8}$in. thick, while that of the smaller

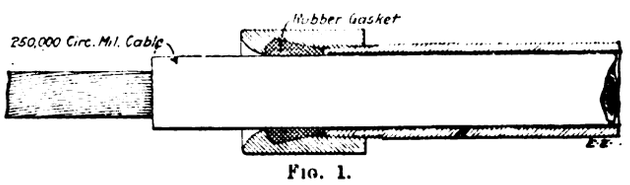


FIG. 1.

conductors is $\frac{3}{64}$in. The specifications called for not less than 30 per cent. of pure Para rubber. This insulation is covered and protected by a single "weatherproof" braid, and in the case of all the wires carrying comparatively heavy current, this braid is covered by a heavy coating of asbestos. The company decided to employ metal pipe conduits, thoroughly grounded, so as to secure the advantages of mechanical strength, durability, protection of wires against injury, and the consequent low maintenance cost. It was foreseen that unless some provision was made for holding the wires rigid at their outlets from the conduits, chafing and insulation would result at these points from the vibration of the cars, even with the usual smooth-edge outlet bushings. A special type of outlet bushing was, therefore, designed for covering the ends of all conduits, and combining the advantages of gripping the wires so tightly that movement would be impossible, while furnishing additional insulating properties at the gripping point. Fig. 1 shows a section of cable fitted with this bushing and

Digitized by Google

a soft rubber gasket. Another interesting feature is the collecting shoe, which is of the slipper type. It is pivoted at a distance of 9in. from the contact rail centre, being held normally in its lower position by a spring on the pivot shaft. The wearing surface of the shoe is carried from the hinged portion by two slender prongs, webbed as indicated in Fig. 2. The prongs of the shoe are purposely made somewhat weaker than the balance of the casting, so that in case of meeting with an obstruction the breakage will occur at that point, throwing the shoe out of service, instead of breaking the supporting hanger and subjecting the contact rail to possible short-circuit. The shoe is arranged with a limit stop, the maximum possible drop

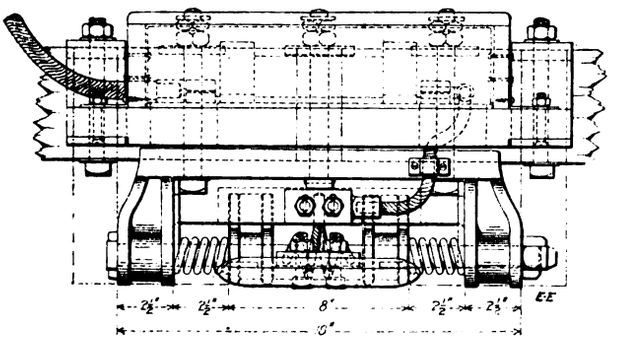

FIG. 2.

being 1½in., though a ⅛in. shim is used to reduce the drop to approximately 1in. The pivoted shaft for mounting the shoe is fastened in place by a key for quick removal. With express trains five motorcars and three trailers are used, and for the local service three motorcars and two trailers, each motorcar being equipped with two 200-h.p. motors.

**Solid-Forged Car Wheels.**—There appears in a recent issue of the *Street Railway Journal* an interesting description of a solid-forged and rolled steel wheel for tramway purposes. This wheel is being manufactured by the Standard Steelworks of Philadelphia, which company has installed a special plant for making the same. The object of the company is to prepare a wheel which shall successfully replace the steel-shod cast-iron wheels or the cast-iron wheels with chilled tyres which have been so largely used up to the present. In the manufacture of this new type the whole wheel is treated with as much care and forged as thoroughly as a tyre bloom, and is subsequently rolled to the required form and size, which so increases the strength of the hub and web that a much lighter design is permissible, reducing largely the weight in comparison with steel-tyred wheels. The method of rolling and arrangement of rolls is illustrated diagrammatically in Fig. 1, from which it will be seen that the arrangement is such that heavy work can be put on the tyre of the wheel. The steel used in the manufacture of these wheels is made from the acid open hearth of composition similar to that used for steel tyres of medium grade of hardness—that is, from ·60 to ·65 carbon. The method of manufacture has, however, appeared to increase the density of structure of the steel, so as to give better wearing qualities than would the steel tyres of the same chemical composition. The billets of steel from which each wheel is made are cut from long vertically-poured ingots, of which only the lower sections are used. These billets are first forged under a 5,000-ton hydraulic press into wheel blanks, which are then rolled into shape in the specially designed mill. This gives a good structure to the steel. The next process is the curving of the web of the wheel to the form shown in the illustration (Fig. 2), which is done in a smaller hydraulic press All the machinery required is electrically driven and arranged for the convenient handling of the wheels in their various stages of manufacture. The machining to be done after the wheels have been rolled and pressed is not much, and consists of facing the hubs and rims and truing the threads to the exact diameter. From

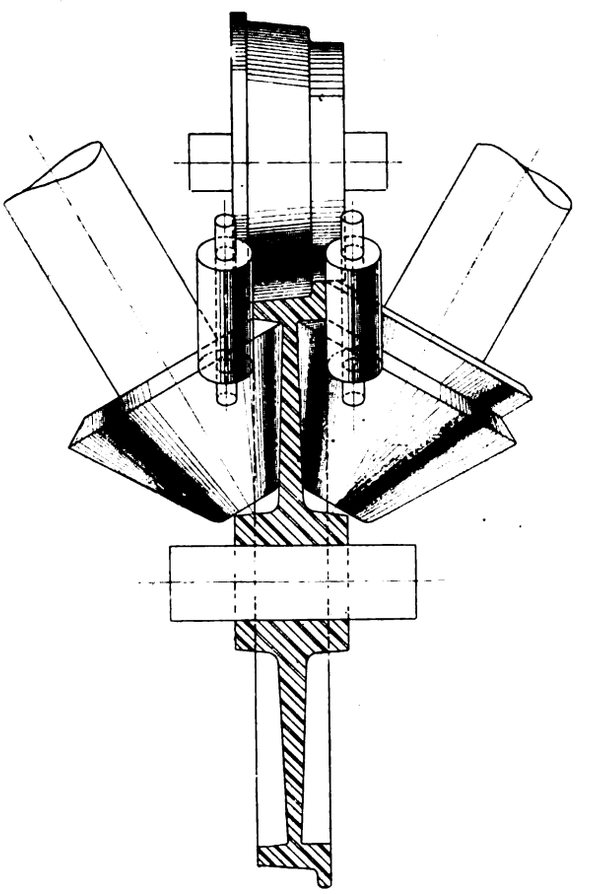

FIG. 1.

figures given in the article before us, we gather that samples of steel cut for these wheels have the high elastic limit of about 52,600lb. and an ultimate strength of about 124,000lb. per square inch. The weight of the finished

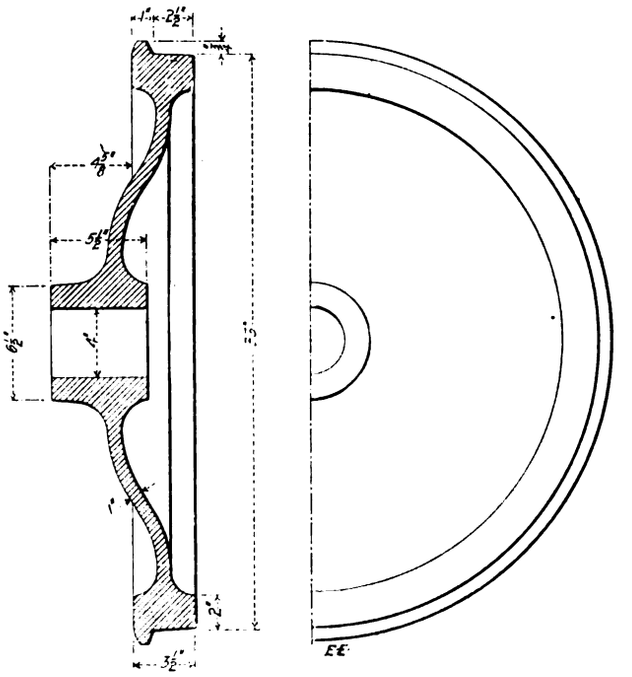

FIG. 2.

wheel, which is suited to freight as well as passenger traffic, is about 425lb. There is no doubt that wheels so formed must be more expensive than those which they replace, but we should expect a much longer life and more satisfaction in service.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

*(Continued from page 332.)*

**Appearance of the Two Forms of Drum Armatures.**

It has been said that the commutator and brush gear of a two-circuit machine may present exactly the same appearance as that of a multiple-circuit machine, but there is one difference in the armature itself which enables us usually to tell at a glance whether an armature is of the two-circuit or multiple-circuit form, particularly when it is bar wound—*i.e.*, with one pair of inductors per commutator section. It is this: since the two-circuit winding goes continually forward from pole to pole, the connection at one end of any inductor is practically parallel to that at the other end; but these two connections run in opposite directions around the armature periphery; so that, on the whole, the inductor with its two end connections will present somewhat the appearance of a distorted letter Z (thus ⥨). With the multiple-circuit winding we pass alternately forward and backward along the armature periphery, so that each inductor with its end connections has the appearance of a distorted letter ⊔ on its side (thus, ⊐); and this difference is commonly visible in modern dynamos.

**Rules for Two-Circuit Simplex Windings.**

We can now set to work to develop the rules which govern this class of armature.

It is better, perhaps, to commence with the idea of *distance-pitch*, so as not to lose sight of the most general case. For the same reasons as those given for multiple-circuit armatures, it is necessary to connect an inductor under the centre of a north pole with an inductor under the centre of a south pole. This would give for a machine with $p$ poles a distance-pitch $= \frac{1}{p}$ of the circumference (or, to make matters more clear, for a four-pole machine each end connection would span one-fourth of the periphery). In such a case, however, after $p$ connections the winding closes, so that for any large number of inductors we must take a different pitch if we wish to connect them into one winding.

We may at once repeat that here, just as much as in the case of multiple-circuit windings, the armature connections are assumed to be regular, so that the pitch at either end of the armature does not change throughout, though the two ends may have pitches differing from one another. Now we may, I think, safely assume that the two following points are obvious enough to need no demonstration.

1. If we consider the distance-pitch to be measured around the armature periphery, then since, after a definite number of such pitches the winding closes (or we return to our starting point), it follows that the length of the distance-pitch multiplied by the number of such pitches is equal to some multiple of the armature circumference in the same measure. This may be calculated in two ways. If we say that the armature is "so many" inches in circumference, then the distance-pitch in inches × the number of connections made = some whole multiple of the armature circumference. On the other hand, if, instead of measuring the armature circumference in inches, we say that it consists of "so many" inductors, then the distance-pitch would be measured by the number of inductor spaces which one connection spans, and thereby becomes what we have hitherto called the "number-pitch." Thus we have the average number of inductor spaces spanned by one end connection × the number of end connections = some *whole* multiple of the total number of inductors. This shows clearly also the close connection existing between distance-pitch and number-pitch.

2. Since the last connection must naturally join on to that end of conductor No. 1 which is open or unconnected, there must be an even number of end connections, or just as many at one end of the

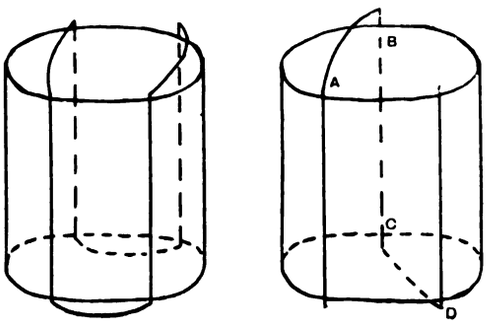

FIG. 17.

armature as at the other. Now, the total number of end connections is obviously equal to the total number of inductors, therefore there *must also be an even number of inductors*. Reference to such a simple diagram as Fig. 17 will soon prove the truth of this statement. It is easily seen that it is impossible to connect any armature with an *odd* number of inductors (such as that shown with 3, Fig. 17) by any regular system whatever. We get connections A B and C D, but then we should have to connect right across the armature from E to F, which, of course, is inadmissible, since it involves the equivalent of inserting another inductor. The armature with 4 inductors, however, connects quite easily. We see, then, that there must be an *even* number of inductors, and that except in the rare case when the number of inductors is equal to the number

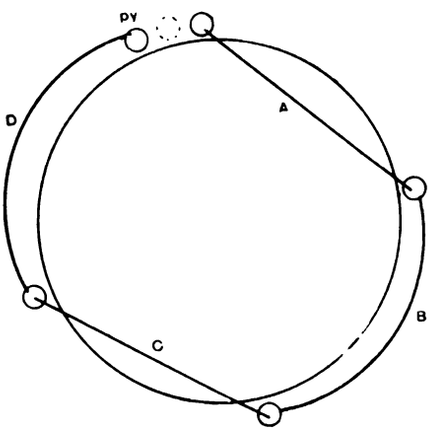

FIG. 18.

of poles, the number-pitch must *not* be equal to $\frac{w}{p}$. If the number-pitch is the same at both ends of the armature, we call it $y$; or if it be different at the two ends, let $y$ = the mean of the two values $y_1$, $y_2$: then we must arrange $y$ so that after having made $p$ connections, we arrive, not at inductor No. 1, but at the nearest inductor to it. For it is clear that the nearer we are to No. 1, after having made $p$ connections, the more nearly will $y$ be equal to $\frac{w}{p}$, which is, as has been shown, an advantage. Referring now

Digitized by Google

to Fig. 18, which represents a four-pole armature, we make the four connections A, B, C, and D, and note that if A and C are at the front of the armature (or commutator end), B and D will be at the back. We also note that the connection which closes the winding must be at the opposite end of the armature to connection A.

Taking at first $y$ as nearly as possible equal to $\frac{w}{p}$, D will be connected to either the last inductor, or to No. 2. In any case, when we have made these four connections, the total number of inductor spaces *spanned* will be $4y$; consequently, if we have arrived at the last inductor, the total number of inductors is equal to $4y + 1$, and if we have arrived at No. 2 it is equal to $4y - 1$, or in the general case

$$w = py \pm 1$$

for such a winding.

Now, since $p$ is of necessity an even number, $(py \pm 1)$ must be an odd number. But we have seen above that $w$ must be an even number, consequently the formula

$$w = py \pm 1$$

is not tenable, a fact which becomes more clear if we try to connect up an armature fulfilling its conditions; for we find ourselves in the difficulty shown in its most simple form in Fig. 17.

**Meaning of "Creep."**

It is convenient here to introduce a word to denote the difference between the number of the inductors up to which the $p$-th (or in this case the fourth) connection brings us, and inductor No. 1.

This difference (representing the amount which the armature winding has progressed) is frequently called the "creep" of the winding. It is clear that it is equal to the figure after the "$\pm$" sign in the formula above. We have tried a creep = 1, and find that it gives an impossible arrangement: we may now take it equal to 2. The formula then is

$$w = py \pm 2,$$

which obviously fulfils the condition, that there is an even number of inductors.

Taking, again, a four-pole case, four times (or generally $p$ times) the mean pitch brings us to the inductor marked $py$, so that

$$w - 2 = 4y.$$

Whence, since $w$ = an even number, $y$ = either (1) a whole even number or (2) an odd number and a half or (3) an odd number.

Thus, if $w = 24$, $y = 5\frac{1}{2}$. Whence $y_1 = 5$ and $y_2 = 6$.
if $w = 26$, $y = 6$.
if $w = 30$, $y = 7$.

The first of these cases is inadmissible, since it does not agree with the first axiom on page 366. In the second case, just as for multiple-circuit windings, only half the number of inductors would be included if $y$ were an even number. We may, however, remedy this by using two pitches, both odd numbers, the mean pitch remaining an even number; thus if

$$y = 6$$

we take

$$y_1 = 7$$
$$y_2 = 5$$

The third case is the commonest of all, and the best generally; since it gives like connections at the two ends of the armature, which from the point of view of regularity and of ease in design is always an advantage.

In this way we arrive at a general formula for simple two-circuit windings:

$$w = py \pm 2,$$

in which, if the connections are to be the same at both ends, $y$ must be an odd number.

Referring now to Fig. 14 we have a four-pole case with a number-pitch of 5.

From the formula

$$w = 4 \times 5 - 2$$

the number of inductors = 18, and we see that after making four connections we arrive at inductor No. 3, giving the winding scheme shown on page 330.

An example of a winding arranged with the end connections differing by two is given in Fig. 19.

The scheme is 1—8—13—20—3—10—15—22—5—12—17—2—7—14—19—4—9—16—21—6—11—18—1.

$$y_1 = 7 \quad y_2 = 5 \quad w = 4 \times 6 - 2 = 22.$$

**Similarity between Multiple and Two-Circuit Windings.**

It is of interest to compare such schemes as those of Figs. 14 and 19 with similar windings for multiple-circuit armatures.

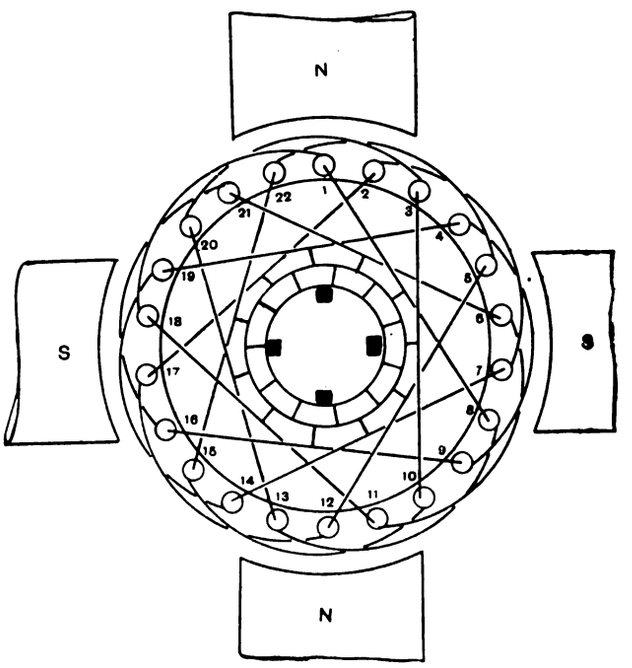

FIG. 19.

For simple windings of the latter type we found that the second connection should bring us to inductor No. 3. Similarly we now find that in these windings the $p$-th connection should bring us to inductor No. 3, or to that which corresponds to it—viz., the last inductor but one. Other points of similarity there are between the two classes of windings, and they will be pointed out as they occur.

*(To be continued.)*

## DISTANCE-CONTROL SWITCHES AND THEIR LAY-OUT IN STATIONS.

BY W. E. WARRILOW, A.M.I.E.E.

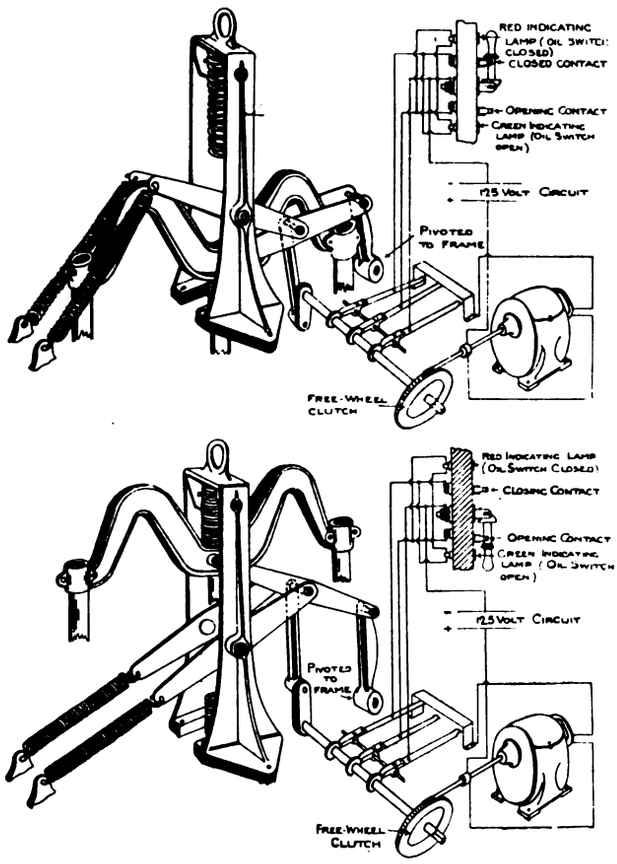
(*Concluded from page 231.*)

**Motor-operated switches have found considerable favour in America, whence the best-known type—that of the General Electric Company—has been introduced into this country and exploited by the British Thomson-Houston Company. It is the practice of this company to place all its large switches in separate brick compartments as a sure safeguard against damage to the neighbouring gear. In**

Digitized by Google

addition, the phases are similarly separated to confine any trouble arising in one limb to that member only.

The switch (Figs. 24 and 25) is almost identical with that described in Fig. 20, save that it is operated by a motor



FIGS. 24 AND 25.—Motor-Operated Oil Circuit Breaker in perspective, showing Motor and Connections (B.T.H.).

instead of by pull magnets. This motor serves to wind up the controlling springs when throwing in the switch, at the same time placing the knuckles of the lever system on a dead centre. The motor, which always runs in one direction, when used for opening the switch, breaks

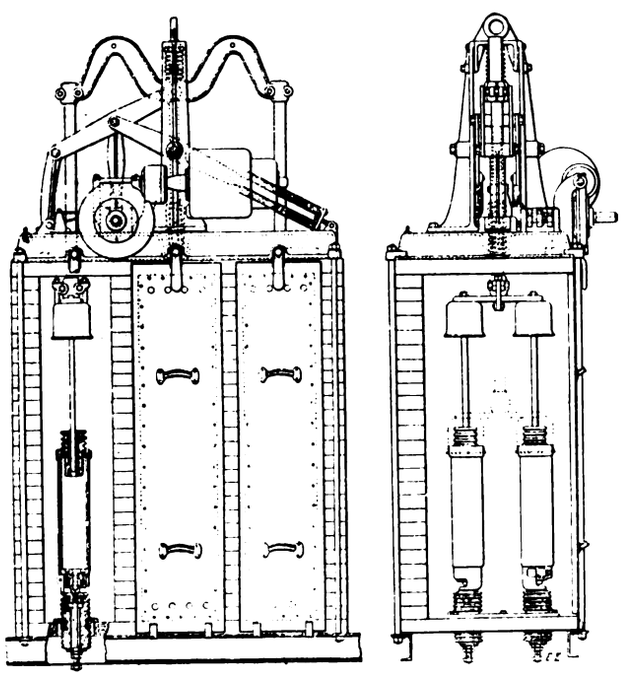


FIG. 26.—View of complete Motor-Operated Circuit Breaker, showing Contacts (B.T.H.).

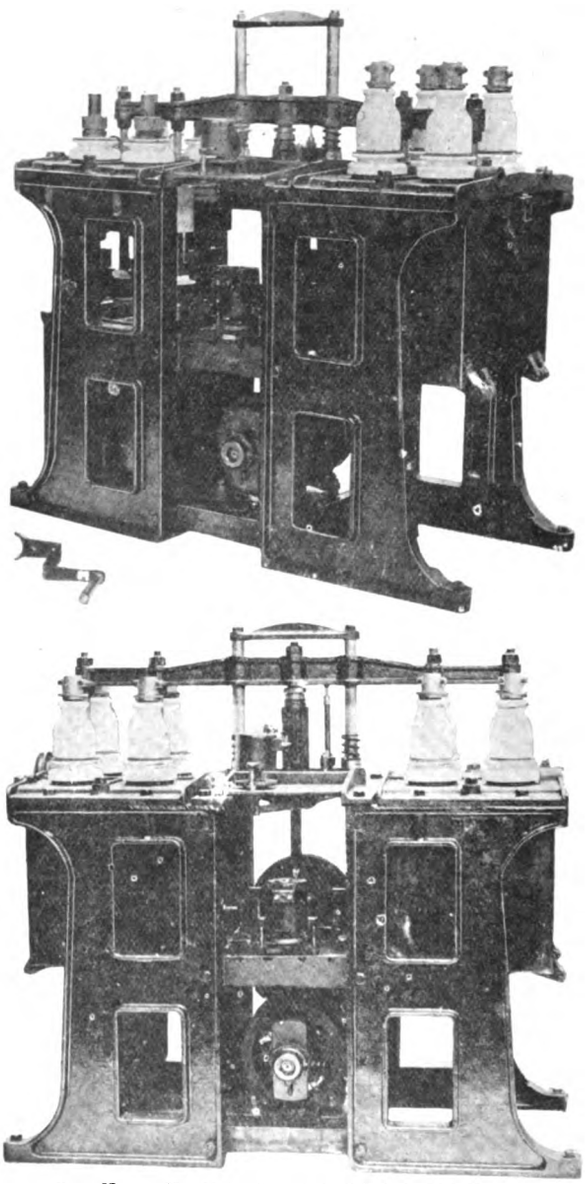
this knuckle when the springs smartly open the switch, the over-running clutch permitting this sharp rotation of the first-motion shaft, independently of the motor. Three cams on this shaft operate three contacts in such a way as to signal to the operating board the position of the switch (by lighting red and green lamps) and keep the motor running should the control switch be released, a circumstance followed at once by its flying to the off position. In this case, however, the contact on the extreme right keeps the motor circuit closed long enough for it to put in the switch; the cam trips it once the switch is closed. A section through the complete switch is shown in Fig. 26, and in this the contacts can be clearly seen. The cable terminal is at the bottom of the switch and quite clear of the oil-chamber. Figs. 24 and 25 will explain the connections and on and off positions of the switch. It will be noticed that, in addition to the controlling springs, there are buffer springs which damp the blow of the cross-head when the switch is opened or closed.

In Figs. 27 and 28 are two views of a new oil switch, the design and production of Dick, Kerr, and Co. The principle of this is almost identical with that shown in Fig. 10 (p. 51), save that the operating is done entirely by a motor controlled



FIGS. 27 AND 28.—Motor-Operated Oil Switch (Dick-Kerr).

from a separate board. Tripping coils for overload and no-voltage release are fitted, and quick break is obtained by a falling weight. In one view the oil-tank is shown lowered to expose the contacts. A switch of this class is self-contained, and need not be enclosed in brick chambers. The lay-out of electro switchgears of this description is subject to much modification, and it is doubtful if any standards will ever be adopted for assembling the various apparatus. Now that circuit breakers, comprising one circuit unit as opposed to switch and fuse, are the recognised practice, less difficulty is experienced in making-up the complete gear. Four main sections can, however, be counted upon (1) the 'bus bars, (2) the switches, or circuit breakers, (3) the operating board, (4) the instrument and relay transformers. In very large plants a fifth

Digitized by Google

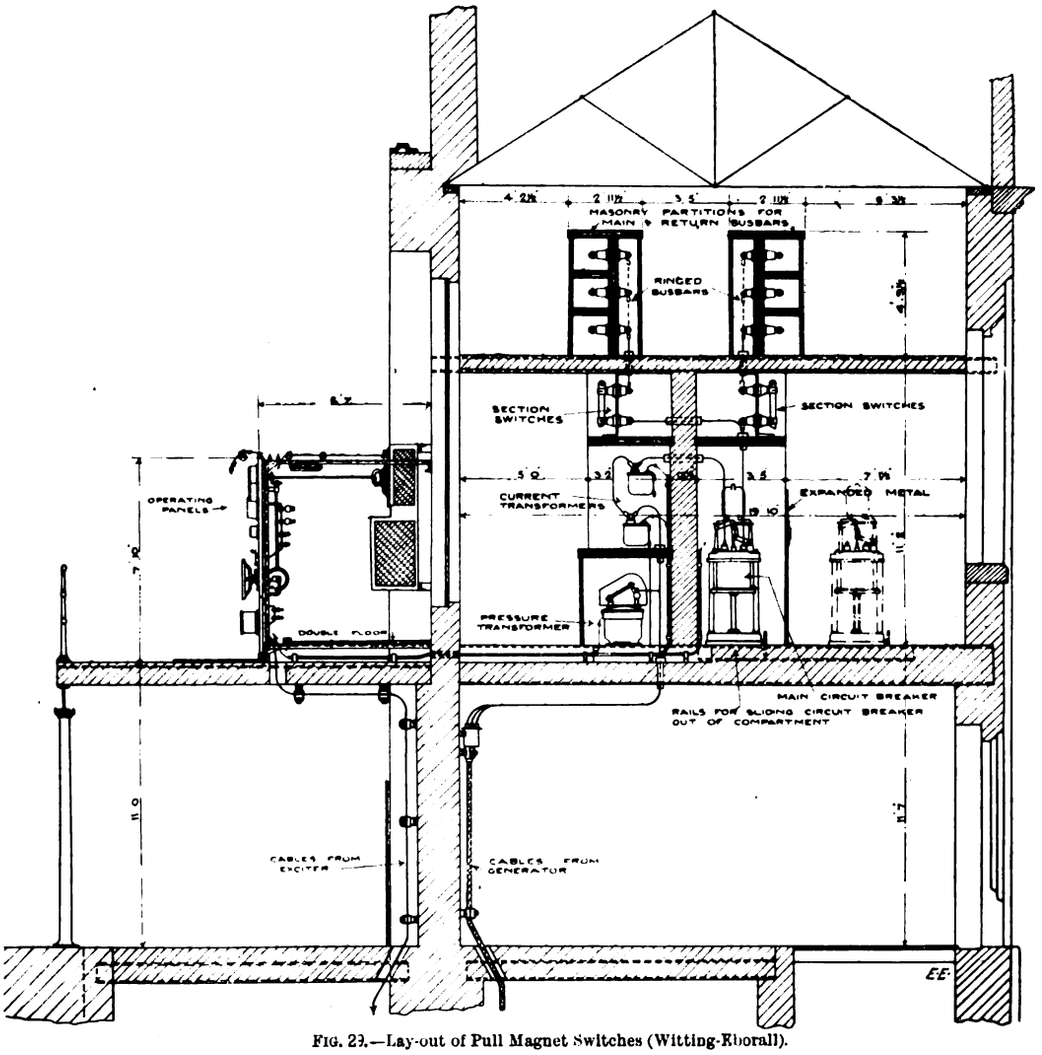


FIG. 29.—Lay-out of Pull Magnet Switches (Witting-Eborall).

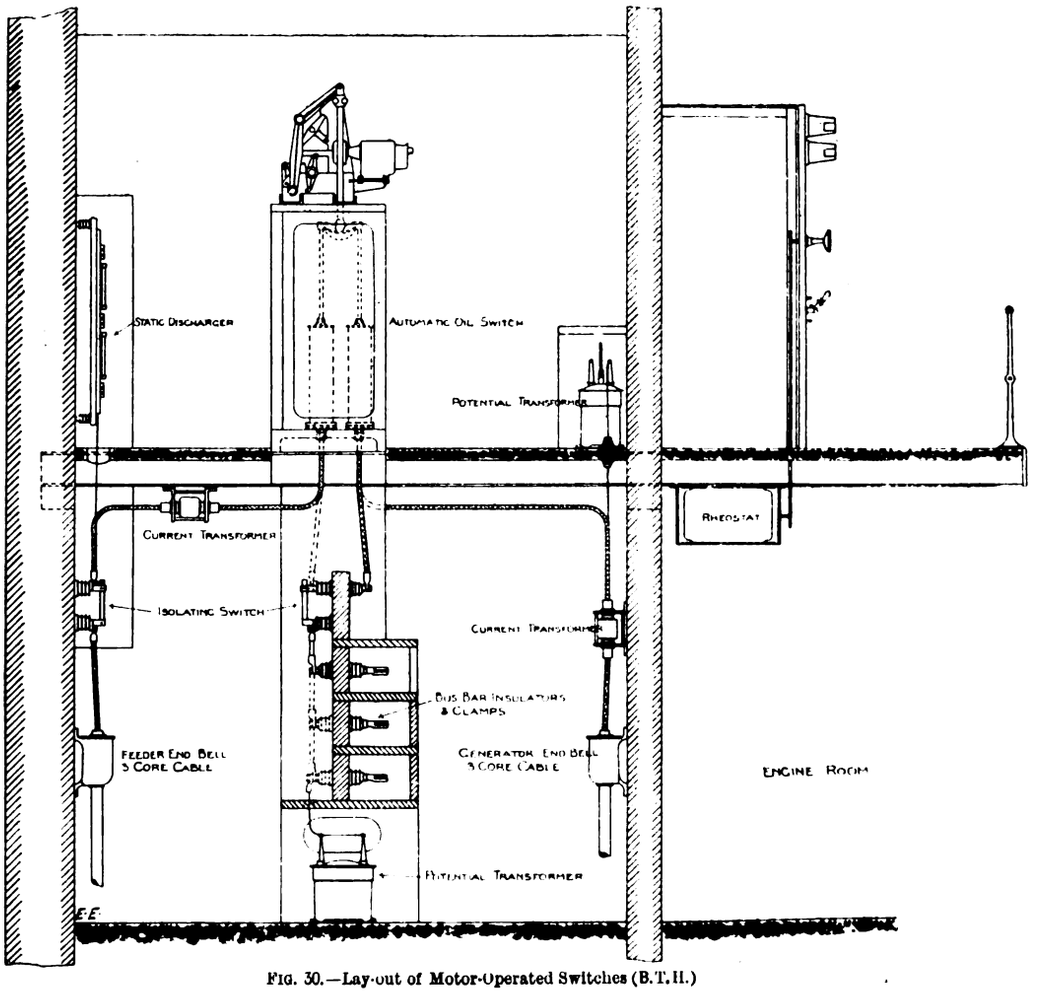

FIG. 30.—Lay-out of Motor-Operated Switches (B.T.H.)

Digitized by Google

may be found in the cable section—a precaution necessary for isolating an important member in the system of energy transmission. Where the voltage is not excessive, care must be taken with the cables, but they need not necessarily be confined to a separate vault.

In Fig. 29 a lay-out of Messrs. Witting-Eborall's pull-magnet switch is shown. The gear requires two floors, one for the controlling gear, high-tension switches, etc., and the other for the high-tension 'bus bars, these latter being at the top of the whole. The high-pressure apparatus is in a separate switch house, and only the controlling board projects into and forms part of the engine-room. The wall of the latter divides off all high-tension gear from the operator, and ensures his complete isolation. As in previous cases with mechanical control, the exciter circuits, low-tension instruments, and control switches only are allowed on the operating board. The high-tension portion is divided by a wall up one side of which pass the generator cables, trifurcated into tails leading through the instrument transformers and main switch to two selector switches, permitting the use of either of two sets of 'bus bars which surmount the whole board. The oil switch can be drawn out to the position shown, for complete inspection, after the cables have been disconnected.

In Fig. 30 the B.T.H. lay-out is shown for the switches described by Figs. 24 and 25. Here a distinct contrast will be noticed in comparison to the lay-outs described above. The high-tension gear is again divided off as before and the control gear placed on a gallery to command the engine-room. In the high-tension room, however, the switches and 'bus bars are placed in the centre in two tiers, while the cables enter and leave the various panels by way of the walls. Referring to the diagram, the generator cable passes up the right-hand wall, through its dividing box and current transformer, and then crosses to the centre under the floor of the switch-room to the switch terminals (which are conveniently below the switch), thence through selector switches to the 'bus bars, these being below the switches. Feeder connections are taken from the 'bus bars through the oil switches, thence through cable bends to section switches on the left-hand wall to the cable terminal box as before. Potential transformers for wattmeters, etc, are placed below the main 'bus bars. Where duplicate bars are provided at the point directly below the switch, selector switches are fitted, permitting the switching of either set of bars to the particular generator or feeder circuit. A glance at this lay-out will at once indicate that the chief item likely to cause trouble, the circuit breaker, is placed in a position which, in case of switch failure, will ensure the damage being confined to the switch itself. The 'bus bars and cables are well out of the way, and as "shorts" are the least likely to occur on these, seeing that they are so completely isolated and partitioned, their location below the switch and in company with the cables should occasion the minimum of anxiety.

It is now considered that the oil circuit breaker is completely reliable, but provision must be made for the exception to that rule determining the factor of safety of any apparatus. In any high-tension switchgear the arc-producing portions of the gear should be mounted above everything else, so that when accidents happen, which they may readily do in large power plants, these parts must "fizzle out in splendid isolation" without shutting down the whole gear.

## ELECTRICAL TRANSMISSION.*

BY G. W. WORRALL, M.SC., M.ENG.

There is probably sufficient energy in a flash of lightning to light the city of Liverpool for a month, and sometimes the spontaneously generated earth currents are sufficient to seriously disturb the regular working of the telegraph line. But this native form of electricity has not yet been brought under sufficiently systematic control to serve the general purposes of man as a prime source of power. It is a fortunate circumstance, however, that this power may be generated under conditions which bring it under the absolute control of the engineer. The generation of the commercial electricity of to-day is brought about by the motion of a conductor across a magnetic field. To produce this motion involves the expenditure of some kind of natural energy. The kinds of energy most readily obtainable at present are the chemical energy of fuels and explosives, and the potential energy of the waterfall. One advantage of transforming these natural energies into electrical energy is in the facility with which the latter may be transmitted, almost regardless of distance, to those points at which there is the greatest demand for its use, and this with the least possible loss. Thus the modern engineer finds it to his advantage to transform natural energy into electrical energy, and electrical energy into mechanical energy. The selection of the natural energy to be thus transformed is a matter of no inconsiderable importance. For the advantage of one kind over another depends not only upon which kind is nearest to the point of demand, but also upon which kind will most economically meet the exigencies of the demand. For instance, suppose that the maximum demand greatly exceed the average demand, then the natural energy should be such as may be drawn upon to a greater or less extent, and without entailing continuity of the upkeep charges necessary to meet the maximum demand. The waterfall fulfils this condition better than other sources of energy, because the plant required for its utilisation is considerably less, and the cost of the energy is a less serious factor. On the other hand, when the demand is more nearly uniform, the generating plant is more fully utilised, and it may be more economical to use such sources of energy as are near at hand than to have an expensive long-distance transmission system to obtain the cheap energy of the waterfall.

These considerations bring us at once face to face with the all-important question of the efficiency of transmission, and to clear the ground one may pardon the statement of the truism that the most efficient transmission is that which is accompanied by the least loss. If R = the resistance of the line and C = the current flowing, then the loss of power in the line = $C^2$ R watts. Hence to obtain the highest efficiency it is essential that the value of the current be low. And as the power transmitted = potential difference on the line × the current, the potential difference must be high. Perhaps next in importance to ensuring the highest efficiency in transmission is to deal with the problem which affects the producers of most commodities—*i.e.*, the ever-varying demand on the source of supply. The parallel system of distribution deals with the problem by maintaining the potential difference constant and varying the current according to the demand. The constancy of the potential difference is maintained by numerous generators connected in parallel, all generating the same potential and capable of being switched in and out at will. The same obtains with regard to the demand. The motors utilising the current being connected in parallel, and thus are all at the potential of the line. In this arrangement of motors there would be a great danger from the high potential were it not that the electricity is transformed from a high potential to one at which it may be more safely handled.

The question next in importance is the form of the current best adapted to these processes of generation and transformation. The two forms of current in general use are the alternating and the continuous. Alternating may be generated at high tension by a single machine, while to generate continuous current at high tension several machines are required, and these in series. The transformation of alternating current from a high to a lower tension may be effected by a stationary transformer or by a motor-generator connected directly across the line, while that of the continuous is only possible by the employment of several motor-generators, the motors in series and the generators in parallel. These advantages have caused alternating current to be generally considered to be the best adapted for high-tension transmission. It must not, however, be thought that continuous current is entirely without advantages, and these principally consist in the facility with which the generators may be switched in and out of circuit, the simplicity of the switchgear which may be employed throughout the entire installation, the facility

* Paper read before the Liverpool University Engineering Society on Tuesday, Feb. 21, 1905.

Digitized by Google

also with which the speed of the motors may be regulated and varied, and the partial absence of such phenomena as inductance and capacity. These advantages have probably led the Edison Continental Company, contrary to general practice, to select continuous current for a somewhat important installation they have equipped at Paris. In this case current is generated at 4,400 volts by groups of two machines in series and transmitted to a distance of 6 km., where it undergoes transformation to 130 and 260 volts by means of motor-generators which are arranged so that there are two motors in series and the generators are in parallel.

The partial freedom from inductance possessed by continuous current is perhaps the greatest advantage so far named. For the presence of inductance is a serious drawback to the use of alternating current, its presence, of course, being due to the very alternation itself, and its action being to oppose current changes and to reduce their value. Now, as the phenomena of inductance and capacity have just been referred to, it may not be out of place here

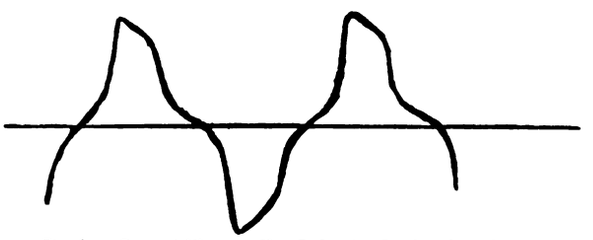

FIG. 1A.—Current Wave on Non-Inductive Load No Inductance. No Capacity.

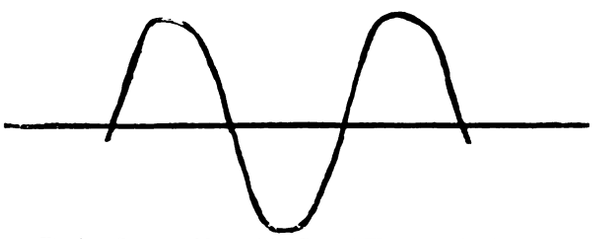

FIG. 1B.—Same machine as (A). Current Wave on Inductive Load. No Capacity.

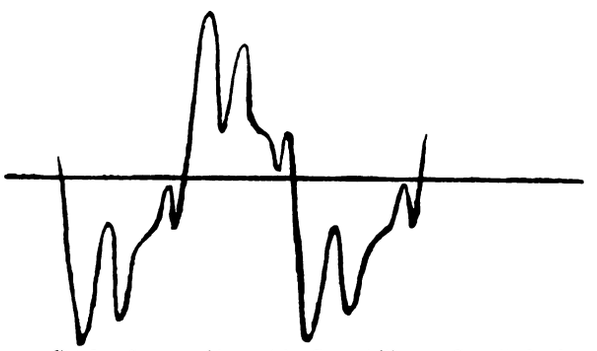

FIG. 1C. Same machine as (A). Current Wave on Capacity Load. No Inductance.

to consider their respective effects in high-tension transmission generally. These effects are broadly due to the tendency of inductance to retard current changes and the tendency of capacity to emphasise them. Thus, in switching on, inductance retards the rise of current, while the capacity of the line causes a rush, and the danger of this rush may be averted by a temporary increase of the inductance. The effect of inductance upon the wave-shape of the alternating current is to cause it to approach the ideal, while the effect of capacity is to further distort it, as shown in the oscillograph records (Fig. 1). In switching off, the inductance may produce such a high E.M.F. as to seriously endanger the insulation of the line, and its disturbing effect upon neighbouring telephone and telegraph wires is well known. The existence of capacity causes the line to remain charged after the circuit has been broken, and in the case of alternating current the potential of this charge may be even higher than that in the normal working. Both in switching on and switching off the combined action of inductance and capacity may produce dangerous electrostatic surgings in the line. All these effects as regards inductance, however, may be minimised by such transposition of the conductors as that the effects in alternate lengths tend to neutralise each other, and also by placing the conductors in close proximity to each other. But as regards capacity, the effects are emphasised by the close proximity referred to, which latter is a necessary part of underground work. And the capacity effects of the materials used in insulation are so much greater than those of air, that for long-distance transmission aerial lines are alone practicable.

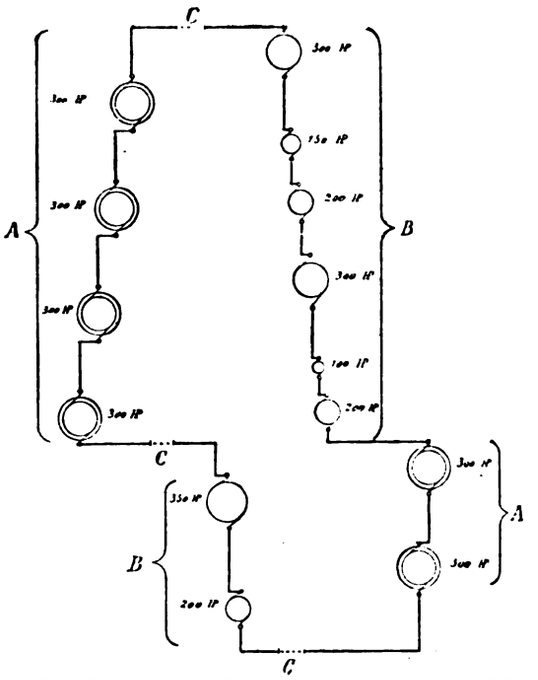

FIG. 2.—Thury Series System of Transmission. A A, generators; B B, motors.

Thus much on the subject of inductance and capacity, and to enter on this discussion has been somewhat of a digression, and it would scarcely be proper to leave the discussion of the respective advantages and disadvantages of alternating and continuous current for high-tension transmission which has been based upon general experience without referring to the special experience of M. Thury, a Swiss engineer,

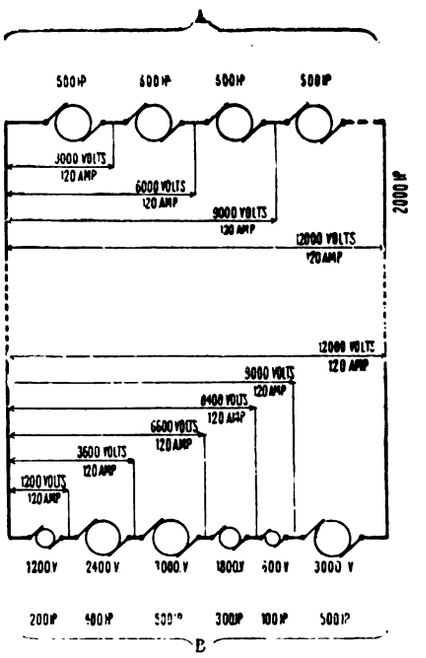

FIG. 3.—Diagram showing Distribution of Voltage on the Thury Constant-Current Series System.

and giving a brief description of, and cursorily remarking upon, the system by which he utilises continuous current for the same purpose. The principle of the system is to generate continuous current at very high tension and constant current, to transmit it to the nearest point of demand, continue it in series through all the points of demand to be supplied, and to return it through an insulated line. Thus as each consumer takes his quotum of energy from

Digitized by Google

the line the tension is lowered. Not only are the points of demand in series with each other, but the groups of motors, or other users of the energy, are themselves in series with each other, so that the tension drops as the current passes through each piece of apparatus in succession. Each piece of apparatus on the line carries the full main current, and the whole of the apparatus is in one single series. The current is generated by machines so

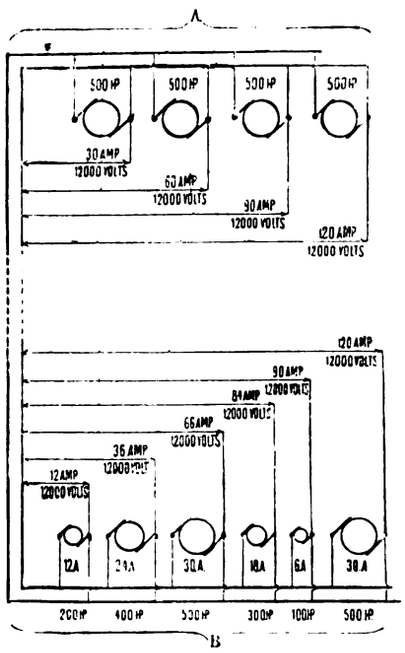

FIG 4.—Diagram for the same Generators and Motors on the Parallel System.

connected in series that as it passes through each machine in succession it is raised in potential by a maximum of about 2,000 volts. Thus 10 machines in series generate a maximum of about 20,000 volts, and the number of machines that may be employed is limited only by the insulation of the line. The variations in demand are met by varying the total potential difference on the line. Small variations are provided for by a regulator, automatic in action, which varies the total potential difference by

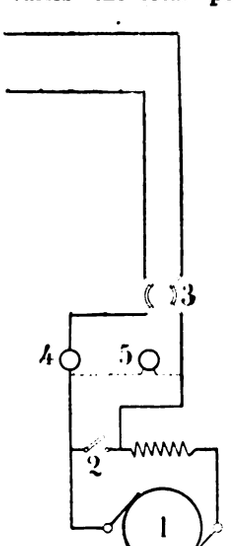

FIG. 5.—Switchgear required for each Generator on the Thury Continuous-Current System. 1 is the generator, 2 the automatic regulator, 3 the short-circuiting switch, 4 the amperemeter, 5 the voltmeter.

adjusting the speed of the entire set of machines running. Large variations in demand are provided for by switching individual machines in and out of circuit, which is effected respectively in each case by disconnection from the automatic regulator referred to, stopping and short-circuiting, and by practically the reversal of the process. It might be thought that the switching of an individual machine in and out of circuit would seriously disturb the entire system. This, however, is provided against by the automatic regulator, which serves to diminish or increase the speed of the machines remaining in, so that they collectively take the total load while an individual machine is being switched in or out.

It has been stated that the most efficient transmission is that which is accompanied by the least loss, and judged by this standard alone the transmission of electricity by the system now under consideration would be found wanting; for while in the parallel system the loss is in some degree proportional to the energy transmitted, in this application of the series system, of which constancy of current is a necessary part, the loss is the same whether the load be large or small. There is no system, however, without its disadvantages, but many of these may be outweighed by the one great advantage claimed for this system by M. Thury, and which consists of connecting in series power-houses of waterfalls situated long distances apart and the points of demand which lie between, which points may be individual factories or cities, and all as they occur *en route* (Fig. 2). Thus electricity at high tension is transmitted from the power-house of a fall to the nearest centre of industry, where, as has been shown, it loses potential. Therefrom and by a continuation of the same conductor to the next power-house *en route*, where it gains potential, and in the same manner through points of further

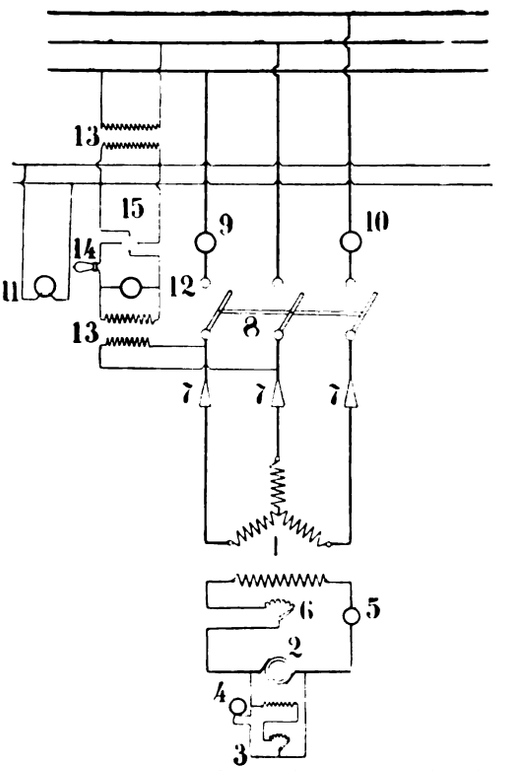

FIG. 6.—Switchgear, etc., required for each generating unit with the Three-Phase System. 1 is the Generator, 2 the exciter, 3 the exciter rheostat, 4 the exciter voltmeter, 5 the exciter amperemeter, 6 the alternator field rheostat, 7 the fuses, 8 the three-pole switch, 9 and 10 the amperemeters, 11 and 12 the synchronising voltmeters, 13 the two synchronising transformers, 14 the synchronising lamp.

demand and points of further supply, forming a huge loop closing at the point from which it started, and this without danger to life or property unless it be possible for the line to become accidentally connected to earth, as it will be remembered that only one line passes through the point of demand. Dwelling for a moment on this system of high-tension transmission, an imaginative mind can scarcely fail to see foreshadowed the decentralisation of industries and the reoccupation of rural hill and dale, where industries may be again pursued in pleasure and health to all. Thus much about M. Thury's generators and transmission, and a word about the motors to close.

Judging from theory, and without experience of the system, the behaviour of these motors would seem to be somewhat peculiar, for, unlike motors of other systems, the armature current would be constant as well as the field, with the result that the driving torque would be constant also. If this latter were less than the torque applied to the pulley, the motor would stop, and if the opposite were the case, the motor would race. These theoretical conclusions appear to have been realised in practice, for the inventor describes

Digitized by Google

a special form of automatic regulator for adjusting the driving torque to that applied to the pulley. The action of this regulator is to shunt the field coils by a resistance, and thus to vary the strength of the field directly with the torque required, equalising the driving torque to that applied to the pulley, and thereby maintaining the speed constant. He further claims that the action is initiated by the speed of the motor itself, and that the regulator may be adjusted to any given speed within certain limits. It will be remembered that short-circuiting is applied to individual generators to disconnect them from the series to which they belong, and the same method is applied to the motors. The short-circuiting is effected by means of a by-pass, which under normal conditions is worked by hand, but which, when the current abnormally rises, is operated automatically. It may, however, be mentioned that in a system in which the current is constant, abnormal rising is infrequent, and overloading is never the cause, so that, contrary to experience with parallel systems, the armatures of these motors are not thereby liable to danger. If M. Thury's expectations are realised in practice, the constant-current system of high-tension transmission, which has for some time been considered impracticable, is established again, and not the least of its advantages is that every motor upon the line, independent of its relation to the source of energy, is supplied with the full amount of power it can take.

[An interesting account of a transmission between Lyons and Moutiers about to be installed on the Thury system will be found on p. 217 of our issue for Feb. 17. In this case voltages up to 57,000 will be needed at full load, but the system will be earthed, so that one-half of this voltage between any part of the line and earth will never be exceeded.—ED *E. E.*]

## A NEW OPERATING DEVICE FOR AUTOMATIC REGULATORS.

The usual method of automatically regulating the voltage of a circuit involves the rise of a delicate relay or contact voltmeter device for the purpose of setting the regulating apparatus (cell switch or resistance switch) in operation. A rise or fall in voltage from the normal deflects the voltmeter and closes a local circuit which starts the regulator in the correct direction for producing the required change in voltage. As soon as the normal voltage is reached again the contact is broken at the voltmeter, and the regulator comes to rest in its new position.

For direct-current circuits the voltmeter often takes the form of a solenoid connected across the voltage to be regulated, and acting on a tubular iron plunger suspended inside it by means of a spring. This plunger carries a contact arm free to make contact with one or the other of two fixed terminals, according to the position of the plunger in the solenoid. The position of the plunger is determined by the opposing actions of the magnetic pull due to the solenoid and the pull of the spring, and a definite position corresponds to every voltage across the solenoid. Any change in voltage causes one or the other of the forces to preponderate to an extent depending on the amount of the voltage change, and the plunger takes up a new balanced position. If a contact is to be closed by this movement, it is clear that the plunger must be arrested before the new balanced position is reached, if there is to be any force available for making the contact. On this account only a fraction of the net increase in pull can be actually employed. Further, the total net increase in pull will itself be very small, because the apparatus must be sensitive enough to act under voltage changes of the order of 1 per cent., so that only something like $\frac{1}{2}$ per cent. of the total ampere-turns in the solenoid can be employed for actually making the contact. The smallness of the actuating forces makes all such apparatus very delicate, and the distances moved through are also very small, so that only very small currents can be dealt with at ordinary voltages. Similar objections apply to contact devices of the Deprez type, in which a coil carrying the current moves in the field of a permanent magnet, and also to those of the Ferraris type, used for alternating currents, in which a metal disc moves under the action of a revolving field against the action of a controlling spring. These objections have led to numerous attempts to solve the problem in other ways, but without much practical success hitherto.

The *Elektrotechnische Zeitschrift* describes a new device, recently put on the market in Berlin, which would seem to overcome most of the difficulties. In this instrument two ordinary horseshoe electromagnets are employed, one to cause increase in voltage when required, and the other to cause decrease in voltage. A single electromagnet would be useless alone, because of the wide difference which would exist between the exciting voltage, which just caused the armature to be attracted up, and that which just allowed the counteracting spring to draw it off again. On the other hand, an electromagnet can be relied on to make satisfactory contact when once the correct actuating voltage is reached, for as soon as the magnetic pull overbalances the pull of the spring the armature moves towards the magnet, and so reduces the air-gap and increases the flux, which still further increases the pull. The armature is therefore drawn on with a rapidly increasing force, in spite of no further increase in voltage occurring, until it comes into actual contact with the magnet, or, at any rate, until the required electrical contacts are securely made. By employing two independent magnets this desirable result can be ensured for both decrease and increase of voltage from the normal, the magnets being set so that at normal voltage the armature of one of them is just on the point of being attracted up by the magnetic pull, and that of the other is just on the point of being pulled off by its spring.

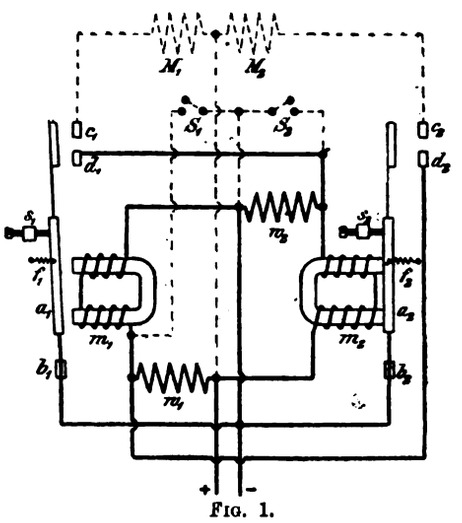

FIG. 1.

The actual connections employed with this apparatus are shown diagrammatically in Fig. 1. $m_1$ and $m_2$ are the two magnets connected to the supply (+ −) through the resistances, $w_1$ and $w_2$. $m_1$ makes contact when the voltage is above the normal, and $m_2$ when it is below the normal. The diagram shows the conditions existing at normal voltage. The adjustment of the screw $s_1$ and the spring $f_1$ determine the upper limit of voltage, and the adjustment of the screw $s_2$ and the spring $f_2$ determine its lower limit. Suppose that an excess voltage occurs. The first effect will be the drawing up of the armature $a_1$, connecting $b_1$, $c_1$, and $d_1$. This sends a current through the voltage adjustment apparatus, $M_1$, by means of which the circuit voltage is lowered, and at the same time the auxiliary switch, $S_1$, is closed. This short-circuits the magnet winding of $m_1$, and so allows the armature $a_1$ to fly back under the action of the spring $f_1$ into its normal position. This return opens the contacts $c_1$ $d_1$ and brings the voltage adjustment gear, $M_1$, back to its normal position and opens the switch $S_1$ again. In this way the original state is reached once more, with the exception that, in the meantime, the voltage has been lowered by the required amount, and so the armature $a_1$ will not be drawn up again. If, on the other hand, the voltage falls below the normal, the armature $a_2$ will be allowed to fall, and contact will result between $b_2$, $c_2$, and $d_2$, and the regulating apparatus, $M_2$, will be energised. This raises the circuit voltage, and at the same time closes

Digitized by Google

switch $S_2$, which short-circuits the resistance $w_2$ in series with magnet winding $m_2$, and so strengthens this magnet sufficiently to ensure the armature $a_2$ being drawn up once more. This opens the circuit of $M_2$ and allows the voltage adjustment gear to return to its normal position, and also opens the switch $S_2$, thus reaching the original condition again, with the exception that the current round $m_2$ is somewhat increased by the rise in voltage effected. The contacts $d_1$ $d_2$ form a safety device for ensuring that both armatures shall never operate at the same time—for instance, owing to sudden voltage variations or to mechanical vibration of the instrument. When $a_1$ is drawn up, the operation of $a_2$ is prevented by the short-circuiting of the resistance $w_2$ through $d_1$ $b_1$. When $a_2$ is down, the operation of $a_1$ is prevented by the short-circuiting of the magnet winding $M_1$ through $d_2$ $b_2$.

The sensitiveness of the apparatus depends entirely on the accuracy of its construction. With the ordinary care obtainable in a manufacturing workshop, and the employment of flat steel springs for the armature supports, fine-thread adjustment screws at $s_1$ $s_2$, and long springs at $f_1$ $f_2$, (ensuring their being stretched by only a small fraction of their length), voltage regulation within a fraction of 1 per cent. can be depended upon. Such accuracy is seldom required in practice—*e.g.*, with cell switches the minimum steps which can be employed are of 1·9 volts each—but the fact that the instrument is capable of such fine adjustment ensures accurate results, whatever the limits may be for which it is set. The contacts consist of copper and carbon, and are so solid in construction, and the pressure with which contact is made is so great, that the instrument can deal with currents of several amperes at 220 volts, and so can be used without additional relays for the operation of quite large motors. The large forces employed prevent the ordinary vibrations met with in engine-rooms affecting the working at all, as they are liable to do in the case of the ordinary contact voltmeter devices, so that the apparatus can safely be mounted direct on the switchboard.

## TEMPERATURE CURVES AND THE RATING OF ELECTRICAL MACHINERY.*

BY RUD. GOLDSCHMIDT, ASSOCIATE MEMBER.

### I.—Short Time Rating.

It is a well-known fact that the energy lost in electrical machines is converted into heat, which causes the temperature of certain parts to rise above that of the surrounding atmosphere, and results in a dissipation of heat by means of radiation or convection. If no dissipation took place at all, the temperature would simply continue to increase in proportion to the time until either the insulation was burnt or the metal was melted. Given the specific heat of the material, the calculation of the temperature rise under any given conditions is a very simple matter, and in the case of the two materials, copper and iron, since their specific heat is nearly the same, we may assume an average value.

As a thermal unit, the kilowatt-hour or watt-second is a more convenient one than the B.Th.U. to adopt, and by this means we obtain the following practical method of measuring the specific heat of copper and iron: "3·5 watts lost in one cubic centimetre of copper or iron raise its temperature 1deg. C per second, supposing that no radiation takes place"; or in British units, "32 watts lost in one cubic inch of copper or iron raises its temperature 1deg. F. per second." If we call the watts lost in the unit volume $W_v$, the initial temperature increase per second V, and the watts per unit volume for the unit of temperature increase per second—that is, 3·5 in C.G.S. and 32 in British units—$C_v$, then

$V$ = initial temperature increase,
$W_v$ = volume watts,
and $C_v$ = rise constant.

The connection between these values is then given by the formula:

$$\text{Temperature increase per second} = \frac{\text{Volume watts}}{\text{Rise constant}},$$

or,

$$V = \frac{W_v}{C_v}$$

In many cases in practice an instrument is used for a few minutes only, and not more than once or twice a day, for instance, with apparatus such as starting transformers, the choking coils of single-phase motors, the small motors used for starting synchronous motors, etc. In these cases it is useless to apply the well-known "watts per square inch" rule for calculating the temperature, and it is a mistaken idea in designing these machines to take into consideration the providing of any cooling surfaces. The heat developed during the time the apparatus is in use is almost entirely spent in heating up the material, and the average temperature attained is too low and the time too short to dissipate any appreciable amount. In many other respects, as will be seen later on, it is of much practical value to study closely the behaviour of machines without taking account of the heat dissipated, but considering only "the initial temperature increase."

We may suppose a choking coil or starting transformer to be so dimensioned that if used only once a day for a period of, say, five minutes (=300 seconds) as a maximum, the temperature rise in any part will not exceed 16½deg. C. The frequency is to be 100 cycles per second, and we may assume that the excessively long starting period of five minutes is due to the fact that heavy weights have to be accelerated with a very low starting current. The temperature increase per second is $\frac{16\frac{1}{2}}{300} = 0{\cdot}055$deg. C. Since a rise of 1deg. C per second is caused by 3·5 watts per cubic centimetre, the energy lost in one cubic centimetre must in this case be $3{\cdot}5 \times 0{\cdot}55 = 0{\cdot}19$ watt. Considering first the question of the heating of iron parts, we have only to look at a hysteresis curve, showing the hysteresis loss per cubic centimetre at different flux densities for the particular iron we are going to use. This curve shows that at 100 periods the flux density corresponding to 0·19 watt loss per cubic centimetre (3·1 watts per cubic inch) is about 15,000 C.G.S. per cm.² (16 Kapp lines per square inch).

With regard to the heating of the copper winding, we must consider the following facts: A copper wire 100cm. in length and 1mm.² section has a resistance of about $\frac{1}{55}$ ohm; its volume is one cubic centimetre. To cause a rise in its temperature of 0·055deg. per second 0·19 watts must be lost in the wire. The current causing this loss in $\frac{1}{55}$ ohm can be obtained directly by Joules's law—

$$C^2 \times \tfrac{1}{55} = 0{\cdot}19, \text{ or } C = \sqrt{0{\cdot}19 \times 55} = 3{\cdot}2 \text{ amperes.}$$

The current per 1mm.² section would therefore be 3·2 amperes, or 2,000 amperes per square inch. Now to obtain a temperature rise of 16½deg. C. in five minutes we found that, quite independently of the size and surface of our apparatus, the flux density in the iron must be 16 Kapp lines per square inch, and the current density in the copper 2,000 amperes per square inch. We have, therefore, with the aid of an example, been enabled to formulate the following rule: "Machines which are to work only for a short time, with interruptions sufficient to allow them to cool down to the temperature of the atmosphere, must be so designed that the flux density and copper density do not exceed a certain amount, independent of size and cooling surface."

We can further conclude from our example that with short-period apparatus the flux density is practically only limited by the permeability of the iron, and not by the heating, since it is possible even under the severe conditions of a frequency of 100, a five minutes' starting period, and a permissible temperature increase of only 16½deg. C., to work at the high flux density of 15,000 C.G.S. per cm². In the example a current density of 3·2 amperes per mm.² correspond to $W_v = 0{\cdot}19$ watt per cubic centimetre, and to a temperature increase of 0·055deg. C. per second. As the watts are proportional to the square of the current density, we can deduce direct a general rule for calculating volume watts and initial temperature increase from the current density. If we denote the current density by the symbol $i$, we have

$$W_v = 0{\cdot}19 \frac{i^2}{3{\cdot}2^2} = 0{\cdot}019 \times i^2 \text{ watts per cubic cm.}$$

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

$$V \text{ per sec.} = 0{\cdot}055 \times \frac{i^2}{3\,2^2} = 0{\cdot}0055 \times i^2 \text{ deg. C. per sec.}$$

or,

$$V \text{ per min.} = 0{\cdot}0055 \times 60 \times i^2 = 0{\cdot}33 \times i^2 \text{ deg. C. per min.}$$

For convenient use tables are appended, giving the temperature rise per minute at different current densities:

Table II. shows the same figures for nickeline wire with a specific resistance 25 times that of copper, and Table III. gives those for iron with a specific resistance equal to six times that of copper. The figures will be found useful in the calculation of starting resistances, the formula being $V = 8{\cdot}5 \times i^2$ deg. C. of temperature rise per minute for nickeline wire, and $V = 2{\cdot}0 \times i^2$ deg. C. for iron.

In determining the section of the wire by means of these data, we are sure of an ample margin of safety as the loss of heat by dispersion has not been taken into account. To be quite accurate, however, a slight increase should be allowed in the temperature values in these tables to compensate for the increase of resistance with rising temperature. We see that for a starting period of one minute with a temperature rise of 70deg. C. per minute, the current density of

$$i = \sqrt{\frac{70}{8\,5}} = 2{\cdot}9 \text{ amperes per mm.}^2$$

(= 1,900 amperes per square inch) in nickeline wire must not be exceeded. A starting transformer or other short-time apparatus would under these conditions have the current density of

$$i = \sqrt{\frac{70}{0\,33}} = 14{\cdot}5 \text{ amperes per mm.}^2$$

(= 9,300 amperes per square inch) in the copper. As already mentioned, the limit of the flux density in the iron is practically unaffected by heating.

There is still to take into account the effect of the insulation. In a field coil consisting of average-sized wire the cotton insulation forms about 5 per cent. of the total weight, and owing to the close contact between the wire and the insulation, both will quickly attain the same temperature. Considering the field coil as a whole, we have no longer to deal with the specific heat of the copper alone, but with that of copper plus, say, 5 per cent. cotton. Assuming cotton to have six times the specific heat of copper, the average value of the specific heat for the coil is $1 + 0{\cdot}05 \times 6 = 1{\cdot}30$ times higher than that of copper alone. The average temperature increase per second might therefore be found to be $\frac{1}{1{\cdot}30} = 0{\cdot}77$. It should be noted that the temperature is lower with field coils of thin wire containing much insulation, and having a higher specific heat than with those having thick wire.

Up to the present it has been assumed that the apparatus gives out no heat to the surrounding atmosphere, but the extent to which this assumption is permissible depends on the kind of machine. With a totally enclosed stationary machine the heat dissipated is only a small percentage of that stored in the heated body itself, say during the first hour of heating. The temperature curve up to this point is an absolutely straight line, or, practically speaking, the temperature increase for the second half-hour is very nearly the same as that during the first half-hour. The following are approximate values for the time during which the apparatus can be considered as giving out no heat:

| | | |
|---|---|---|
| Revolving machines, | open | 20 minutes. |
| ,, ,, | totally enclosed | 40 ,, |
| Stationary ,, | open | ½ hour. |
| ,, ,, | totally enclosed | 1 ,, |
| Starting resistances, and generally single wires | | ½-2 minutes. |

## II.—THE TEMPERATURE CURVE.

Having dealt with the simplest case first, we will now proceed to the other extreme. The temperature of an apparatus will be supposed to have attained a constant value. Theoretically, this state can only be obtained after an infinite time, but actually it is so nearly arrived at within a few hours that a small fluctuation in the temperature of the atmosphere leads to perfect constancy. Under these conditions, the temperature reached by the heated body is sufficient to dissipate all the heat developed, and no further storing of heat—*i.e*, increase of temperature—will take place. This constant temperature is dependent on the lost watts, on the ventilation, on the cooling surface, and on the temperature of the surrounding atmosphere.

For the sake of simplicity we will assume in the whole of the following investigations that the air is at zero temperature. With a given amount of ventilation the difference in temperature between machine and atmosphere is directly proportional to the watts dissipated from one square inch of surface. For instance, in a field coil of an ordinary continuous-current generator, in order to obtain a temperature rise of 90deg. F. (50deg. C.) above that of the atmosphere, measured by resistance rise, about 4¾ square inches (= 30cm.²) cooling surface are required for every watt lost. In other words, a difference in temperature of 90deg. F. dissipates 0·21 watt from every square inch of surface, or $\frac{1}{4\,7\,5}$ watt per square inch per 1deg. F. rise. To state this in C.G.S. units, $\frac{1}{1\,5\,0\,0}$ watt is dissipated by one square centimetre of surface for an increase in temperature of 1deg. C. Henceforward we shall only employ C.G.S. units, and thus apply the factor $\frac{1}{1{,}500}$, which we will denote by the symbol $C_h$ (heating constant). The watts dissipated per unit of surface we will call "surface watts," symbol $W_s$. Surface watts = heating constant × temperature difference.

$$W_s = C_h \times t.$$

Digitized by Google

With the definitions of volume watts ($W_v$) and surface watts ($W_s$), the rise constant ($C_v$) and heating constant ($C_h$), it will be possible to solve any problem in connection with the temperature rise of electrical machines, for intermittent or continuous load, without complex mathematical calculations. And it is proposed to follow the method previously employed of demonstration by the aid of a definite example, which will take the form of a field coil with a heating constant $C_h = \frac{1}{1500}$ and a rise constant $C_v = 4{\cdot}5$. In determining $C_v$, the cotton insulation has been allowed for by increasing the figure from 3 5 to 4·5. The surface watts are assumed

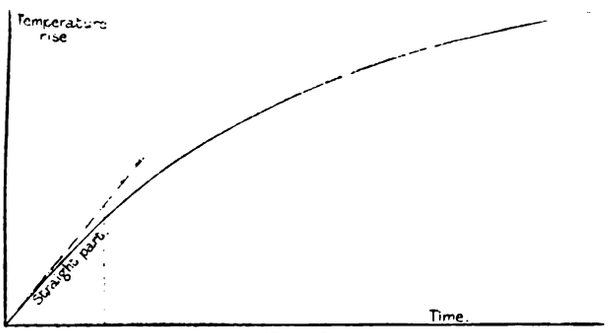

FIG. 1.

to be $W_s = 0\ 033$ watts per square centimetre, corresponding to a final temperature

$$t_f = \frac{\cdot 033}{\frac{1}{1500}} = 50\text{deg. C.}$$

The current density may be 1·7 amperes per mm². The initial temperature increase according to Table I., without taking into account the cotton insulation, would be 0·71deg. C. per minute. We have assumed in this case that the cotton insulation raises $C_v$ in the ratio 4·5/3·5. Consequently

$$V = 0{\cdot}71 \times \frac{3{\cdot}5}{4{\cdot}5} = 0\ 55\text{deg. C. per minute.}$$

When the final temperature of $t_f = 50$deg. C is reached, the heat developed—*i.e*, that amount which would increase the temperature 0·55deg. C. in one minute, neglecting cooling—is completely dissipated in the atmosphere in the same time of one minute. The whole of the 0·55deg. C rise per minute is neutralised by the cooling action. From this fact we may deduce the method for calculating the temperature at any desired instant. For example, at a given moment the body may have a temperature of, say, $t = 35$deg. C in excess of that of the atmosphere. Then the cooling action is less than that in the final state in the ratio of 35/50, and thus compensates for $35/50 \times \cdot 55 = 0{\cdot}39$deg. increase per minute. These 0 39deg. are completely neutralised by the cooling action, therefore, at the instant when the temperature of the body is 35deg. C in excess of the air temperature, the temperature increase per minute is 0·55 − 0 39 = 0 16deg. C. Thus we obtain the rule: "If the temperature of the body has attained, say, $\alpha$ per cent. of the final temperature, the increase of temperature per minute is $(100 - \alpha)$ per cent. of the initial increase."

Assuming that the temperature at a certain instant was known to be 35deg. C., this rule enables us to calculate the

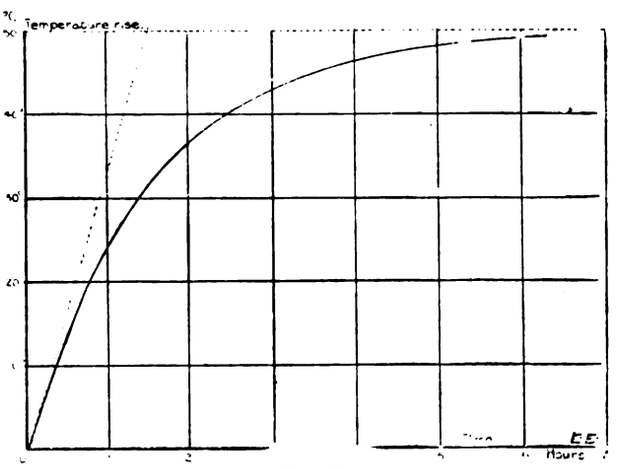

FIG. 2.

temperature, say, 20 minutes later. At the beginning of this 20 minutes' period the rise is, as we have just seen, 0 16deg. per minute. If the rate of increase were the same right through, after 20 minutes the temperature would be $0\ 16 \times 20 = 3\ 2$deg. C. higher—that is, it would now be 38·2deg., but the average temperature during the 20 minutes would be $\frac{38\ 2 + 35}{2} = 36\ 6$deg.—so that the corrected rise is

$$\frac{0{\cdot}55}{50}\ (50 - 36{\cdot}6) = \frac{1}{91} \times 13{\cdot}4 = 0{\cdot}15 \text{ per minute,}$$

or a total of $0{\cdot}15 \times 20 = 3$deg. The corrected temperature after 20 minutes would accordingly be 35 + 3 = 38deg. This value differs so little from the uncorrected one (38·2 deg.) that further correction is unnecessary.

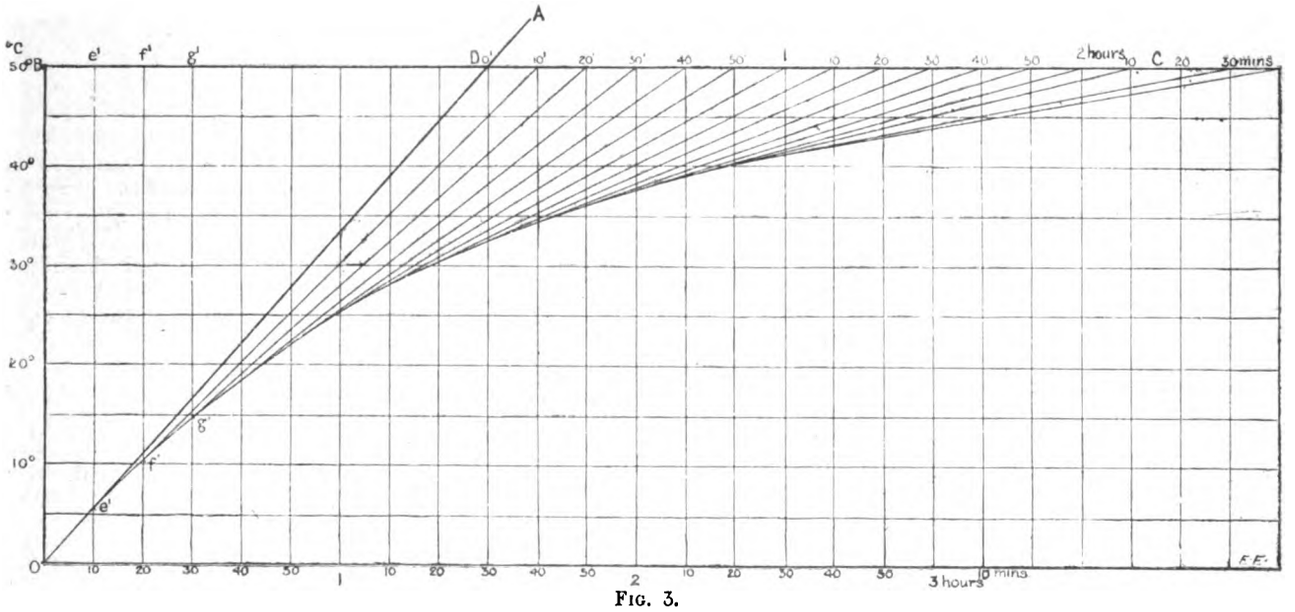

FIG. 3.

The full temperature curve may be calculated in the following manner: We first record our constants once more:

Surface watts, $W_s = 0{\cdot}033$ watts per sq. cm. of surface.
Current density, $i = 1\ 7$ amps. per sq. mm.
Heating constant, $C_h = \frac{1}{1500}$ watt per sq. cm per degree.
Rise constant (with cotton), $C_v = 4{\cdot}5$.
" " (without cotton), 3·5.
Final temperature, $t_f = \frac{W_s}{C_h} = 1{,}500 \times 0\ 033 = 50$deg. C.

Initial temperature increase from Table I. for a current density of 1·7 amperes per square millimetre = 0·71deg. per

Digitized by Google

minute without cotton, or $0.71 \times \frac{3.5}{4.5} = 0.55$deg C. per minute with cotton. The temperatures at intervals of 20 minutes, as determined by these data, are given in Table IV.

TABLE IV. (See Curve, Fig. 2.)

| Time. | Temperature in the beginning of the 20 minutes' interval, $t_1$. | Uncorrected temperature increase $E_1 = \left(1 - \frac{t_1}{50}\right) \times .55 \times 20 = 11 - .22 \times t_1$ | Average temperature during the interval, $t_m = t_1 + \frac{E_1}{2}$. | Corrected temperature increase $E = 11 - .22 \times t_m$. |
|---|---|---|---|---|
| Hrs. Min. | | | | |
| 0 0 | 0 | 11 | 5.5 | 9.8 |
| 0 20 | 9.8 | 8.8 | 14.2 | 7.9 |
| 0 40 | 17.7 | 7.1 | 21.2 | 6.3 |
| 1 0 | 24 | 5.7 | 26.8 | 5.1 |
| 1 20 | 29.1 | 4.6 | 31.4 | 4.1 |
| 1 40 | 33.2 | 3.7 | 35 | 3.3 |
| 2 0 | 36.5 | 3 | 38 | 2.6 |
| 2 20 | 39.1 | 2.4 | 40.3 | 2.1 |
| 2 40 | 41.2 | 1.9 | 42.2 | 1.7 |
| 3 0 | 42.9 | 1.5 | 43.6 | 1.4 |
| 3 20 | 44.3 | 1.2 | 44.9 | 1.1 |
| 3 40 | 45.4 | 1 | 45.9 | 0.9 |
| 4 0 | 46.3 | 0.8 | 46.7 | 0.7 |
| 4 20 | 47 | 0.6 | 47.3 | 0.6 |
| 4 40 | 47.6 | 0.5 | 47.8 | 0.5 |
| 5 0 | 48.1 | 0.4 | 48.3 | 0.4 |
| 5 20 | 48.5 | 0.35 | 48.7 | 0.3 |
| 5 40 | 48.8 | 0.3 | 48.95 | 0.25 |
| 6 0 | 49.05 | — | — | — |

These results can be obtained even more easily in a simple graphical way (see Fig. 3). Draw line O A to represent the initial rise, which in our case is 11deg. per 20 minutes, and B C at a distance O B equal to the final temperature (50deg. C. in our case) parallel to the axis of the abscissæ. The lines cut one another at the point D. We next divide both the axis of the abscissæ and line D C (starting from point D) into intervals of 10 minutes, and draw verticals through every division point on this axis. The first of these verticals cuts O D at the point *e*. Join point *e* with point $10^1$ on line D C. Line $e - 10^1$ cuts the 20 vertical at *f*, then join *f* with $20^1$ on line D C. Line $f - 20^1$ cuts the 30 vertical at *g*. Join *g* with $30^1$ on D C, and so on. In this manner we get a number of lines which "envelop" the temperature curve. To construct this curve we have chosen intervals of 10 minutes only, whilst with the analytical working 20-minute intervals were used. The greater exactness is necessary because we now neglect the "correction" taking $E_1 = E$, and thus regard the cooling action as being dependent on the initial temperature of the interval. A comparison with the calculated values shows that the graphic method gives results which are sufficiently accurate for practical purposes. The two lines O D and D C determine the whole temperature curve. Therefore the form of all curves is similar, and having once plotted one it is applicable to all other cases. The only alterations necessary are the scales of temperature and time.

*(To be continued.)*

## MESSRS. EVERETT, EDGCUMBE, AND CO.

### REMOVAL OF WORKS TO HENDON.

In our issue for Dec. 16, 1904, we gave an illustrated description of many of the specialities of this firm, and some views of their workshops at Great Saffron-hill. We then mentioned the fact that the growth of the business had compelled the firm to build larger works at Hendon. These are now in full swing, and afford a striking proof of the rapid expansion of the company. Thus the business of Messrs. Everett, Edgcumbe, and Co. was founded, as our readers may remember, in 1900. After 18 months the expansion of the business was so great that a move into larger premises in Great Saffron-hill had to be made, and now, after three more years, the growth of the business has necessitated another exodus. A large site was obtained last autumn on the Edgware-road near Hendon, and in October the erection of a factory was begun. Four and a half months later the building was complete and ready for occupation, and now we hear that the work is in full swing there. The whole of the building has been carried out by the firm themselves, and they may be congratulated upon a very smart piece of work. The new factory is known as the "Collindale Works, Hendon, N.W," and will be devoted exclusively to the manufacture of electrical measuring, testing, and controlling instruments.

Offices have now been taken on the first floor of 87, Victoria-street, where not only can the various instruments be seen and examined, but also a member of the firm will almost always be found to discuss and give expert advice upon any question relating to the measurement or control of electrical energy.

Personal attention is the essence of success in such a business, and we are pleased to hear that Mr. G. J. Lemmens has joined the firm. This gentleman's extensive experience in instrument matters will greatly strengthen their position. After the 25th of this month all communications should be addressed either to the works at Hendon or to 87, Victoria-street, S.W.

## FORTHCOMING EVENTS.

FRIDAY, MARCH 17.

**Institution of Mechanical Engineers.**—At 8 p.m., "First Report to the Steam-Engine Research Committee," by Prof. D. S. Capper.

**Institution of Electrical Engineers (Manchester Students' Section).**—At 7.30 p.m., "High-Tension Switchgear," by Mr. C. R. St. John.

**National Physical Laboratory.**—At 3.30 p.m., annual general meeting at Bushy House, Teddington.

SATURDAY, MARCH 18.

**Institution of Electrical Engineers (Manchester Students' Section).**—At 6.30 p.m., annual dinner.

MONDAY, MARCH 20.

**Society of Arts.**—At 8 p.m., "Telephony," by Mr. H. L. Webb (Cantor Lecture II.).

**Institution of Electrical Engineers (Newcastle Section).**—"Electrically-Driven Lifts," by Mr. F. O. Hunt.

TUESDAY, MARCH 21.

**Institution of Civil Engineers.**—At 8 p.m., paper to be further discussed, "Shipbuilding for the Navy," by Lord Brassey, K.C.B. The succeeding paper will be "Coolgardie Water Supply," by Mr. Charles Stuart Russell Palmer.

**Royal Institution.**—At 5 p.m., "Engineering Problems," by Prof. W. E. Dalby (Lecture I.).

THURSDAY, MARCH 23.

**Institution of Electrical Engineers.**—At 8 p.m., discussion on "The Effect of Heat on the Electrical and Mechanical Properties of Dielectrics" and "On the Temperature Distribution in the Interior of Field Coils," by Mr. E. H. Rayner, M.A., communicated by Dr. R. T. Glazebrook, F.R.S.; and "On Temperature Curves and the Rating of Electrical Machinery," by Mr. R. Goldschmidt.

**Royal Institution.**—At 5 p.m., "The Reasonableness of Architecture," by Mr. T. G. Jackson, F.S.A. (Lecture I.).

FRIDAY, MARCH 24.

**Physical Society.**—At 5 p.m., at University College, "Note on the Voltage Ratios of an Inverted Rotary Converter," by Mr. W. C. Clinton; "On the Flux of Light from the Electric Arc with Varying Power Supply," by Mr. G. B. Dyke; "The Application of the Cymometer and the Determination of the Coefficient of Coupling of Oscillation Transformers," by Prof. J. A. Fleming, F.R.S.; exhibition of cymometers and other instruments.

**Institution of Civil Engineers.**—At 8 p.m., students' meeting. "The Wanki to Victoria Falls Section—Victoria Falls Railway," by Mr. C. T. Gardner; and "Design of a Double-Line Plate-Girder Railway Bridge," by Mr. H. S. Coppock.

**Royal Institution.**—At 9 p.m., "A Pertinacious Current," by Sir Oliver Lodge, F.R.S.

**Electro Harmonic Society.**—At 8 p.m., smoking concert in King's Hall.

SATURDAY, MARCH 25.

**Royal Institution.**—At 3 p.m., "Electrical Properties of Radioactive Substances," by Prof. J. J. Thomson, F.R.S. (Lecture III.).

**Institution of Electrical Engineers (Manchester Students' Section).**—Visit to Liverpool and Southport Electric Railway. Leave Victoria Station at 2.10 p.m.

---

**Institution of Civil Engineers.**—The thirteenth "James Forrest" lecture will be delivered by Colonel R. E. B. Crompton, R.E., C.B., on Monday, April 10, at 8 p.m., the subject being "Unsolved Problems in Electrical Engineering."

## STANDARDS FOR ELECTRICAL INSULATION.

The Engineering Standards Committee issued last year an interim report dealing with the standardisation of electric generators and motors, both for the direct-current and alternate-current systems. We published this report in our issue for Aug. 12, 1904, and expressed the hope that the standard sizes in it would be adopted by all English electrical manufacturers. This report was incomplete, because the committee could not lay down the safe limit of temperature either for continuous or intermittent working. In order to ascertain this a very extensive series of experiments have been carried out at the National Physical Laboratory by a sub-committee under the chairmanship of Dr. Glazebrook. The reference to this sub-committee included investigations on (1) the maximum temperature to which the insulating materials at present used in the manufacture of electrical apparatus could be exposed for lengthened periods of time without electrical or mechanical deterioration; (2) the permissible rise in temperature deduced from these experiments; (3) the relation between the mean temperature of any coil obtained by measurement of rise of resistance and the maximum temperature of the hottest portion of the same coil. The investigations on the first and last points have been carried out by Mr. E. H. Rayner, and were communicated last week by Dr. R. T. Glazebrook to the Institution of Electrical Engineers. We give elsewhere in this issue a brief *résumé* of this report, which indicates the vast amount of labour involved in the researches. The work has been carried out partly at the National Physical Laboratory and partly at the works of those manufacturers who have co-operated with the committee by providing the field-magnet coils to be experimented on. The figures actually obtained are, however, the more valuable because they have all been arrived at under similar conditions and under the supervision of the same skilled expert, which renders them strictly comparable. Up to the present the experience as to the safe limits for heating has been of the trial and error order, with the result that each manufacturing firm has accumulated information for their own use, and this even is frequently of an unreliable nature. As a result the temperature rises specified in enquiries for electrical plant are usually on the safe side. Also the method laid down of ascertaining the rise of temperature from the exterior of the insulated windings of a machine, is no criterion as to whether the interior portions of these windings may not reach a temperature which may be damaging to the insulation. It seems probable, however, that even these accepted limits for the temperature rise of dynamo conductors may be considerably increased without any ill effects resulting. The figures given as to experiments on a number of different field coils, both when in the laboratory and when placed on the dynamos under normal working conditions, are most valuable. After careful analysis they will enable a designer to avoid in future dimensions for coils which entail a large difference between the mean temperature of the coil and the maximum temperature in any one part. It seems, from the results given, that this difference seldom reaches 25 deg. C., and that it can be kept within much lower limits if certain precautions are adopted in the design of the former or coil. The work done to ascertain the change in the electrical and mechanical properties of the usual types of insulating material when subjected to high temperatures for extended periods is even more valuable. It is clearly shown from the figures that it is the mechanical properties of the materials which break down under heating The power to withstand a high voltage test is not so affected, and we return to the old problem of finding an insulating material whose mechanical properties

Digitized by Google

shall remain satisfactory under all conditions of working. The figures given in the report help largely in the selection of insulation from this point of view. Indirectly there is a great deal of light thrown on the troubles which manufacturers of electrical machinery have had to surmount. For instance, the influence of moisture on the insulating properties of various materials is enormous. Experiments were therefore made to show how far the use of insulating varnishes would affect the other properties of the materials commonly used. Again, the absorption of moisture by the cotton covering of insulated wire was experimented with and figures obtained which show what an important department the drying ovens are in an electrical manufactory. With these figures before them, the Engineering Standards Committee will be able to draw up some general conclusions on temperature rating which will, we think, greatly assist English manufacturers in their competition against foreign firms. It is well that before these conclusions are issued there should be a free discussion on the facts, such as is to take place at the Institution next week. It is also well that there will be under discussion at the same time the most valuable paper by Mr. R. Goldschmidt on "Temperature Curves and the Rating of Electrical Machinery."

## TRAMS OR MOTOR 'BUSES.

In the first issue of the *Commercial Motor* Mr. Manville writes in defence of electric trams, Colonel Crompton in favour of the motor omnibus. However, when the matter is well considered the main conclusions of these great authorities are easily reconcilable. Both agree that under favourable conditions trams are excellent, both agree that under favourable conditions motor 'buses are better than trams—the line of demarcation is not, and cannot rigidly be, drawn, and in the middle way the fight in the future will wax fast and furious. Colonel Crompton makes two points which should never be forgotten: (1) cost per passenger car mile is determined by the average number of persons carried, not by the maximum that can be carried, and (2) that the kind and condition of road surface has much to do with the maintenance cost of motor 'buses. Mr. Manville very properly points out that electric trams use their own road beds, and wear and tear only their own portion of the roads, which they have to maintain.

# CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

## MR. MARCONI'S LECTURE.

SIR,—Your note in your issue for March 10 on Mr. Marconi's lecture at the Royal Institution shows some misunderstanding as to what Mr. Marconi said with regard to speed of working, which you will perhaps permit me to correct.

The speed of 24 words a minute, over a distance of 152 miles, which Mr. Marconi quoted, is not a new result, but relates to some stations which have been working for more than a year, and represents the average speed of those stations doing commercial work. As it happens, the messages sent are in Dutch, and they are transmitted by operators ignorant of that language. The 24 words a minute is not the maximum speed attained by the stations, but the average working speed under commercial conditions calculated over a long period. Probably the average working speed would be slightly higher were the messages transmitted in a language comprehended by the operators. The maximum speed attained in transmission by the stations in question is from 30 to 35 words a minute, the speed being limited by the capacity of the operator to read by sound.

The arrangement shown by Mr. Marconi at the Royal Institution lecture was the magnetic detector plus a recording instrument. The magnetic detector is capable of receiving impulses at a very high speed, but as hitherto it has not been found practicable to work in conjunction with it recording apparatus, no messages have been sent by its means at a higher speed than that at which the fastest sound-reader is capable of reading. When a recording apparatus is connected to the magnetic detector and an automatic transmitter used at the transmitting station, the average speed is very much higher than 30 or 35 words a minute. Probably the speed shown at the Royal Institution was about 60 words a minute, but it is not practicable with the comparatively primitive arrangements possible in a lecture hall to achieve the best results, and when the new arrangement is worked between commercial stations a considerably higher speed can be attained.

The speed of the De Forest instruments mentioned by Captain Lionel James, if higher than the speed of the stations to which Mr. Marconi referred as working at 24 words a minute, was higher solely because more expert sound-readers were employed. There are no wireless telegraph instruments of any kind other than those referred to by Mr. Marconi at his lecture which are capable of working at a higher speed than 30 to 35 words a minute.—Yours, etc.,

H. CUTHBERT HALL,
Managing Director, Marconi's Wireless Telegraph Company, Limited.

## THE LIFE OF NERNST BURNERS.

SIR,—I send you herewith records I have kept of two installations in Gloucester where Nernst lamps are used. The lamps are ½-ampere B type, on 220 volts continuous-current Corporation supply. The deplorable results obtained with the new-type U-filament burner, as compared with the old-type burner, are very marked. In both cases the lamps hang perpendicularly, and are well up out of reach.

Taking the installation with the old-type burners first. The records date from June 1, 1903, to March 7, 1905. Nine lamps are in use, with 200-volt burners and 30-volt resistances, and all renewals have been made with old-type burners. Four of the lamps have been lighted 1,056 hours, and five lamps for 2,420 hours, during the above period of 88 weeks. This gives a total of 16 324 lamp-hours, and 20 burners have been renewed; $\therefore \frac{16,324}{20} = 816{\cdot}2$ hours' average life of burner. Five resistances have also been renewed within the period.

We now come to the installation (a church) with the new U-type burners. The record dates from the first use of the lamps—Oct. 2, 1904, to March 7, 1905. Thirty lamps are in use, with 210-volt burners and 20-volt resistances. The lamps have been lighted a total of 66 hours during the above period of 22 weeks. This gives a total of 1,980 lamp-hours, and 21 burners have been renewed; $\therefore \frac{1,980}{21}$ = 94 3 hours' average life of burners. Two resistances have also been renewed. More than half of the burners in this case had the heating coil broken, and in the remainder the filament had shorted on to the heating coil.

The Nernst lamps will have to be discarded in the latter installation if they do not give better results. A remedy is badly wanted, or the makers will have reason to deplore their retrograde movement in compelling the use of the unreliable U-type burner in place of the earlier burner which had proved its serviceable qualities.

I would also add that, even if old-type burners could be obtained, they cannot be inserted in the new-pattern B lamp, as the casing of the latter is not sufficiently large in diameter to take them.—Yours, etc., WAWAMIEE.

[Our correspondent has had exceptionally bad experience with the new type of Nernst lamp, which is not in accord with what we hear of the performance of these lamps in other places. We wonder if the position of the church is at the end of a feeder, or if the curve of voltage variation on Sundays will explain the trouble.—ED. *E. E.*]

## APPRENTICESHIP.

SIR,—Having a son who will leave school next summer, and who intends going in for electrical engineering, I should

Digitized by Google

be much obliged if you could give me some information about a firm at Loughborough, the name of which is Falcon. The boy is at school in Leicester, and is 16 years of age Also if you could inform me what you would consider a reasonable premium in apprenticing a youth to that trade.—Yours, etc., W. EDGERS.

[The information our correspondent requires as to the premium pupil system at the Falcon Works and elsewhere he should obtain direct from the different firms. We cannot pass editorial opinions on such personal matters, or on the amount of premium which may have to be paid.—ED. *E.E.*]

## THE CHANT OF THE MAINS MEN.

When the meter will not mete, and there's fireworks in the street,
And the navvy with the pick comes limping in,
When the neutral and the negative are coupled up consecutive
'Cause the jointer mixed the whisky with the gin,
Let us warble "Rule Britannia," and include "God save the King"
(And the brolly trickles water down your back).
For we've only got to test, and to do our very best
To deserve our little modicum of tin, tin, tin,
To deserve our little modicum of tin.

When the network's done a short, and the insulation's nought,
And the telephone is kicking up a din,
When the penny's in the slot, but the lights have gone to pot,
And the Gas Concern is trying not to grin,
Chant the Hallelujah Chorus, ask Bill Bailey to return
(And the Megger's disappeared Idunnowhere).
For we've only got to test, and to do our very best
To deserve our little modicum of tin, tin, tin,
To deserve our little modicum of tin.

When the ganger's gone to quod, after pinching copper rod,
And the Wright's Demand complaints are coming in,
When the pilot volts are low, and the fuses start to blow,
And the copper losses make your hair grow thin,
Let us shout the "Deathless Army," let us dance a Highland Fling
(And we shan't get any rise at all this year).
For we've only got to test, and to do our very best
To deserve our little modicum of tin, tin, tin,
To deserve our little modicum of tin.

## MANCHESTER SECTION DINNER.

The fourth annual table-gathering of the Manchester Section of the Institution of Electrical Engineers was held on the 10th at the new Midland Hotel. Over 200 members and friends took part in the proceedings, and the new arrangement of small tables and clique-parties was of great promise for a record in social frivolity as well as in point of numbers; but, alas! the good example of last year's function, as to limited verbosity, was not followed, and this, together with the indistinctness of some of the speakers, produced a general apathy as to the official proceedings, which was increased by the unfortunate proximity of the American bar to the banquet hall.

Mr H. A. EARLE, in proposing "The Institution," was retrospective in commenting on the changes in the appearance of members' hair since he first knew them; he dilated upon the advantages of the periodical gatherings (without referring to the jovial after-meetings), and did not forget the standard topic of standardisation.

Mr. W. M. MORDEY, in replying as an ambassador from the village section, referred in complimentary terms to the high standard of the papers and discussions in Manchester. As a member of the body of men known to some as "insulting" engineers, he considered that this class should be standardised, if it would prevent the great competition that now existed among them, and he believed that this standardisation will come in time. The President of the Institution had been invited to become chairman of the committee appointed by the Institution of Civil Engineers which was to consider the question of the international standardisation of electrical matters. He referred to the progress of the Institution of Electrical Engineers, and the 5,700 at present on the muster roll. He looked to the youthful members to improve on the older ones, but trusted they would not replace the extinct volcanoes too soon. Mr. Swinburne had remarked that new members spent their time in trying to show old members how much they knew, and old members spent theirs in trying to prevent the new members from finding out how much they themselves did not know.

Mr. C. D. TAITE referred to that hardy annual castle-in-the-air, the Institution of Electrical Engineers' own building, and commended the advantages of membership to the meeting. Some men had said that there was no honour in becoming a member, but he pointed out that the new rules for admission were not so easy-going as formerly, and that the status of membership had gone up.

Dr. E. HOPKINSON proposed "Our Guests," which was responded to by the MAYOR OF SALFORD and Mr. F. E. PRIEST.

Mr. J. S. RAWORTH proposed "The Trade of Manchester and Salford" in his usual felicitous terms, the MAYOR OF SALFORD again treating the audience to a lengthy display of his oratorical gifts in reply.

The capital musical programme that was arranged by Mr. P. C. Pope had to be shortened, to the disgust of those who had come on pleasure bent, Mr. Pope's own later contributions being sacrificed. Mr. E. Hastings, although considerably bothered by the ceaseless devotion to business throughout his performance of the polyglot waiters, was in splendid form in his Corney Grain sketches; and Mr. R. L. Gamlen's songs also pleased. A flashlight photograph of the diners was taken during the evening.

## REPORT ON TEMPERATURE EXPERIMENTS CARRIED OUT AT THE NATIONAL PHYSICAL LABORATORY.

The following abstract of the paper read by Mr. E. H. Rayner, M.A., A.M.I C.E, before the Institution of Electrical Engineers on the 9th inst. deals only with the class of experiment performed. The results of the trials on the various insulating materials and field coils are so extensive that any condensation is impossible. The first part of the work was to determine the effect of heat on the electrical and mechanical properties of dielectrics. For this, samples of the materials to be tested were subjected to temperatures varying from 75deg. to 100deg. C. in an electric oven. Other samples were heated in an oven from 100deg. to 125deg. C., and a third set were subjected to temperatures from 125deg. to 150deg. The four samples of each material were then subjected to high alternating pressures and the disruptive voltage obtained. The alteration in the mechanical properties due to baking at the above temperatures were ascertained by two methods. The force required to punch a hole $\frac{1}{2}$in. in circumference was ascertained. The specimen was then bent round cylinders of gradually decreasing diameter until it broke or was badly cracked. The diameter of the cylinder was decreased to $\frac{1}{16}$in., and if the sample stood this it was bent backwards and forwards up to 10 times, or until it broke. Comparative figures are given of 32 different substances, although in several cases the thickness of the material is the only variant. For each of these the disruptive voltage after the different baking processes are given, and in another column the volts per millimetre of thickness are added. The variation in the disruptive voltage with the increase in temperature to which the substance is subjected is never more than 20 per cent. from the mean. The results, however, as regards the mechanical properties of material clearly show a very great decrease of strength due to the baking. The brittleness as revealed by the bending test is greatly increased.

Trials as to the insulation resistance of these materials show that there is little relation between the ohmic resistance and the disruptive pressure. The insulation

Digitized by Google

resistance increased very rapidly with heating, owing to moisture being driven out of the specimens. It was also found that in many instances the insulation resistance decreased largely with an increase in the testing voltage. The experiment shows that heating was the most effectual way of removing this moisture from the body of the dielectric. Other experiments on the same lines were carried out with a dozen different substances which had been treated with a Berrite varnish. It is interesting to compare these results with those on the same substances unvarnished.

The second part of the investigation was to determine the temperature distribution in the interior of field coils of continuous-current generators. For this purpose thermo-electric couples were inserted within the windings of the coils by the manufacturers of the same. The junctions used were of iron-eureka, as this combination has a high thermo-electric voltage and a fairly straight-line law over the range required. The junction wires were No. 25 gauge, each being double silk covered, and the pair again covered with a single layer of silk. The actual junction was made between the wires by a silver solder. The result was a very compact flexible arrangement for the measurement of temperature at a point. The voltage was recorded by a sensitive moving-coil galvanometer by R. W. Paul, which, by the adjustment of resistance in series, was made to read directly in degrees Centigrade. With this arrangement temperatures can be read to within 0·2 of a degree, and the curves given are said to be accurate to well within 1deg.

We believe it is the first time that low-temperature researches have been carried out with such thermo-junctions, and the report shows what a valuable method it is of determining temperatures at exact points. A number of these thermo-junctions were inserted in each of the nine different field coils experimented with. As a rule five were placed on a median cross-section of the coil and three on the opposite side as a check. The five thermo-junctions were placed on the cross-section where the highest temperature was expected to occur. As a rule the second thermo-junction from the core recorded the highest temperature. Other thermo junctions elsewhere in the coil enabled the distribution of temperature to be still further studied. The results for each coil are plotted by the author in the form of curves, which are interesting as showing the temperature gradients. With the nine coils in question no less than 30 different sets of experiments were made. In some of these the coils were actually in place on the dynamos for which they were designed, and the machines were running at normal speeds either at full or no load. In each case records were taken of all the electrical and mechanical quantities involved. These are presented in the form of two tables, and a number of results are calculated from them. For instance, there are columns which show the watts per square inch of cooling area, the temperature on the surface of the coil, the maximum internal temperature, and also the mean. Perhaps the most interesting column is that numbered 18, which gives the difference between these two latter temperatures. The figures in this column vary between 2deg. and 36deg. C., but under normal working conditions 25deg. C. is not exceeded. The table is completed by columns which give the quotient of the maximum internal rise by the watts per square inch of cooling surface. This figure is one which will be of great service to designers. In the course of the experiments it was found that sometimes the resistance of a field coil rose during the first few hours of use, and then fell to a very considerable extent. Experiments made with cotton-covered wire suggest that the fall in resistance was due to short-circuiting caused by water driven out of the cotton by the rise in temperature. As has been recently shown, such moisture may cause further damage due to electrolysis. The formers on which the different coils were wound and the protection of the winding were variants which enable useful deductions to be made from the figures given. The actual figures contained in the report will be obtainable from the Engineering Standards Committee in due course at a small charge, which will go towards defraying some part of the high cost of the experiments.

## NOTES ON SOME EFFECTS IN THREE-PHASE WORKING.*

BY W. M. THORNTON, D.Sc., MEMBER.

(*Concluded from page 351.*)

### § 3. Presence and Origin of 23rd Harmonic.

The presence of this high harmonic of large amplitude in normal three-phase working has not, I believe, been previously observed. Since it appears in the open-circuit voltage, it must arise in the movement of the magnetic lines across each slot. Every line is first retarded by the slot, then suddenly snaps across it. The voltage induced in the wires within the slot is, therefore, not sinusoidal but of the following form (Fig. 17A), the zero line being taken to cut off equal areas above and below. This wave-form can be produced by the superposition of two curves, one twice the frequency of the other, as shown at *b*; so that, since by the mechanical motion of the poles the first distorted form, *a*, is produced, the result on the main voltage will

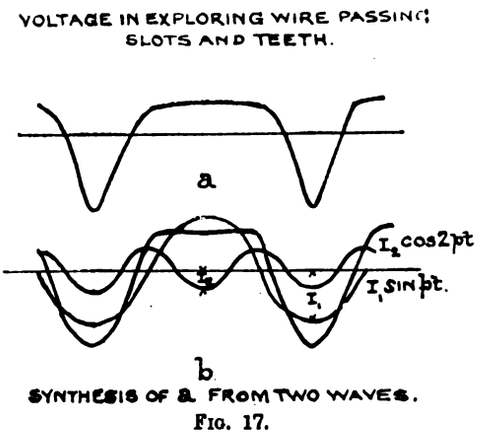

Fig. 17.

be two ripples, corresponding, in the case of a machine with two slots per pole per phase, to 12th and 24th disturbances, *both of which must always occur*. Their magnitude depends upon the relative reluctances of slot and air-gap, a short gap favouring the production of the higher harmonics. A low flux density in the teeth, giving them higher permeability and so causing the lines to be held by them a little longer, may also be a source of these high harmonics. Their greater prominence in the Brown-Boveri generator is probably aided by the surface winding of the magnet rotor and a low density in the armature teeth. The practical importance of this is that in a wide network of mains trouble is much more likely to arise from machines with short air-gaps or low saturation on account of this high harmonic. In addition to which, every harmonic increases the "copper" loss in the circuit.

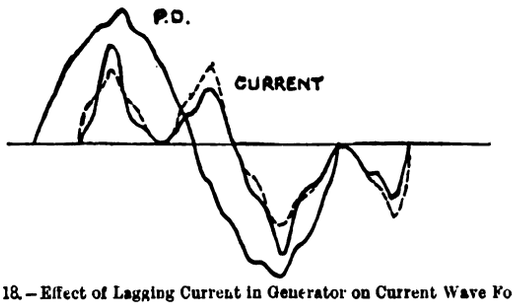

Fig. 18.—Effect of Lagging Current in Generator on Current Wave Form

The effect of harmonics upon cable losses is a matter for further investigation. Steinmetz has found that dielectric hysteresis follows the same law as that in iron, the energy loss per second being proportional to the frequency and to the 1·6th power of the voltage. Thus if there are two similar wave-forms, one having one-twentieth the amplitude of the other, but 23 times its frequency, the loss from that with the higher frequency will be as much as 20 per cent. of that from the other having 20 times its amplitude. Of course, a harmonic only causes fluctuation and not reversal of stress, but the high index 1·6 may make the former as important as reversal of the same amplitude about zero.

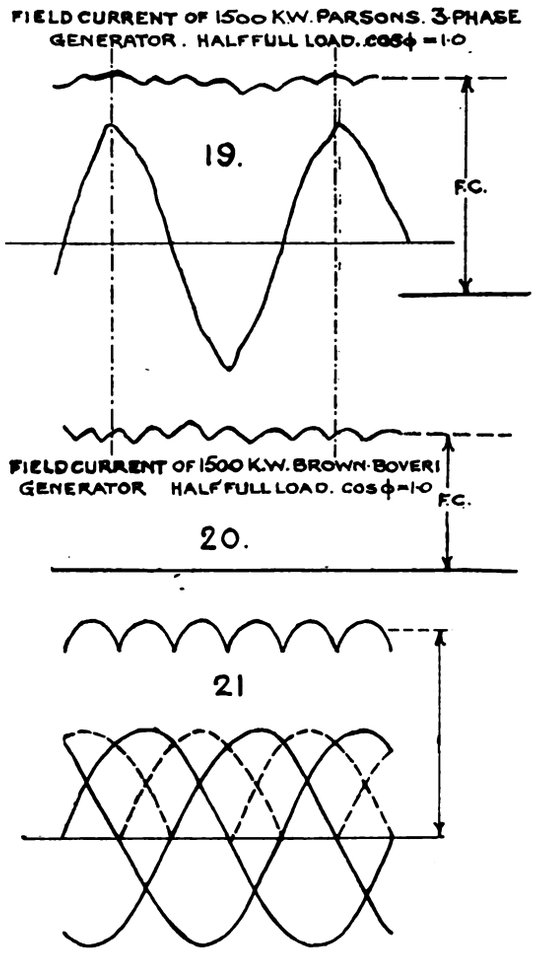
### § 4. Current Wave in Under-Excited Generator.

As an example of the effect of under-excitation upon the output current of a machine running in parallel, Fig. 18 is given. This is the current in one of the windings of a turbo-generator with a light load. There are here two effects—the dip in the curve and the swing of the ordinate between the dotted limits.

* Paper read before the Newcastle Local Section of the Institution of Electrical Engineers, Feb. 27.

Digitized by Google

The curve shows a very strong 3rd harmonic in phase with the generated wave, and nearly equal to it in amplitude, added to



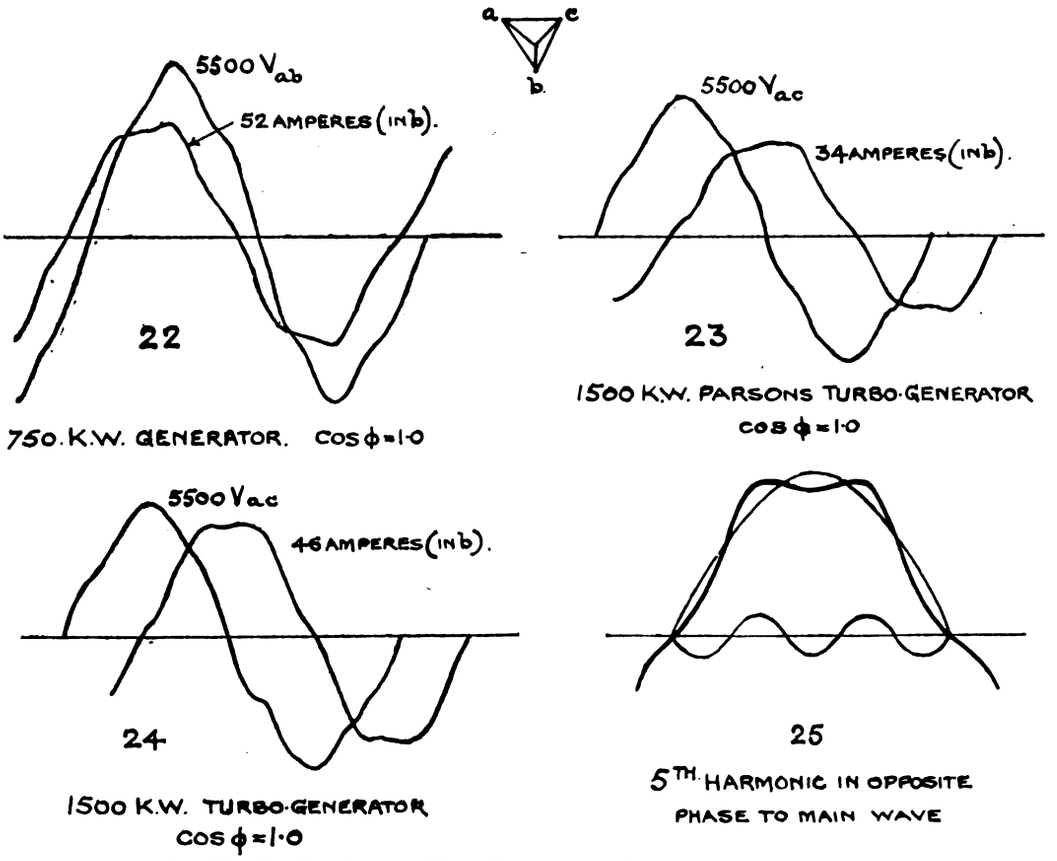
FIGS. 19 TO 21.—Effect of Armature Reaction on Exciting Current of Three-Phase Generator on Load.

windings—so that the magnetising current component is ·37 of the whole. It is well known that hysteresis in iron distorts magnetising current waves by giving rise to harmonics, of which the 3rd is the most important. In the given curve the distortion is aided by the way in which the machines were connected. When generator windings are joined "three-wire star," no 3rd harmonic can exist; but when the neutrals of generator and motor are earthed, the ordinates of the 3rd harmonic in each phase are added, and a triple-frequency current flows in each winding and to earth. Moreover, the magnetising component of the current in a motor reacts in opposite phase to that in a generator with regard to the voltage. A 3rd harmonic in the motor is, therefore, in phase with one in the generator, and a triple-frequency current circulates through the machines. As the excitation was raised, the dip in the curve disappeared at about quarter full load, and the current became approximately sinusoidal.

### § 5. Periodic Variation of Exciting Current in Three-Phase Machines.

The reaction of a large demagnetising component upon the field circuit must in the above case have been very marked. Unfortunately, no record of this was taken at the time, but some fifteen months later I obtained Fig. 19, which is the exciting current of the same machine with a load of 160 amperes. There are here six well-defined waves per period superposed on the continuous exciting current. These arise from the double-frequency magnetising effect of the current in each phase in turn. The existence of these three-phase field disturbances has been disputed, but that they probably exist in all machines and do not depend upon a particular design, is seen by their being equally pronounced in the Brown-Boveri generator (Fig. 20).

The calculation by which the back ampere-turns of armature reaction are found in theory to be perfectly steady, assumes that "the effect of a constant current in the armature coils varies as a sine curve when their position is reckoned from the centre of a pole." The influence of the breadth-coefficient of the winding is also neglected. That these assumptions are only approximate, which is all they are said to be, and do not represent the true facts, is here shown to be the case. The following diagram (Fig. 21) may help to make the origin of these ripples clearer. The lower halves of the curves have been reversed to show their action, irrespective of coil position. The positive and negative maxima lie under opposite poles, and the effect on the magnetic circuit is cumulative. Note the correspondence between the general shape of this ripple and that of the actual current, and that the former are most marked in the Brown-Boveri machine. On open circuit the field current is practically straight.



FIGS. 22 TO 25.—Wave Forms and Power Factors of Three-Phase Generators on Water Load.

which is a 13th. To explain the origin of the 3rd, it must be first noted that the curve is lagging with regard to the bus-bar voltage by an angle of 53deg.—that is, 23deg. in the

### § 6. Power Factor of Large Generators on a Water Load.

There has been some discussion recently upon the fairness of testing large alternating-current generators on a water load, on

Digitized by Google

account of the lead said to be produced by the capacity effect of the electrolyte. The following curves (Figs. 22, 23, 24) may therefore be of interest. By careful measurement of Fig. 22 it is found that the angle between voltage and current on the paper is 28½deg., but this is caused by the presence of a harmonic which has the effect of bringing the curves nearer on the zero line. Taking the equivalent sine wave, the angle is exactly 30deg. Again, with the Parsons turbine the angle is 90deg. at 34 and at 46 amperes. The possible error in these measurements—due to the oscillograph cam—is about 3deg. Since the cosine of 87deg. is ·998, the power factor of large generators on a water load may, therefore, be taken as unity, with a possible error either way of one-fifth per cent.

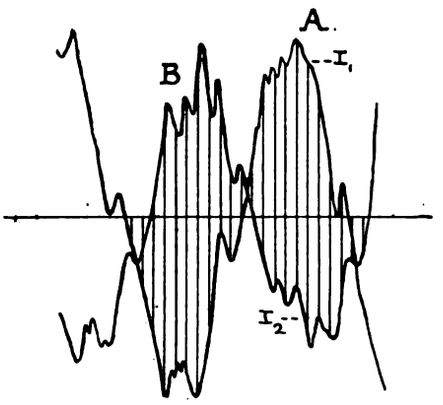


FIG. 25.—For corresponding Voltage Wave Form see Fig. 6 in phase with A. Cos $\phi$ = ·95.

The tops of the current waves are in all three cases flattened. This has nothing to do with the liquid resistance, but is caused by the 5th harmonic having changed its phase by 180deg., as may be seen by comparing Fig. 25 with Fig. 1. In the generator wave this harmonic was nearly in phase with the fundamental; now it is opposite to it at the start of the period. As a generator the machine was connected "four-wire star"—*i.e.*, with neutral point earthed—but now the water resistance forms a mesh across the line wires, and the earth connection on the generator is removed. It can be shown that the phase position of an *n*-th harmonic changes when the connections are changed from four-wire star to mesh, either by 180deg. or not at all; in this case by 180deg. But why should the Parsons machine, which has apparently only higher harmonics than the 5th, show the latter in the current? The answer is, I believe, to be found in the field ripples of the preceding section. There are six of them to a period, produced by armature reaction, and their further reaction upon the armature current is brought out in a striking manner by this shift of phase due to mesh connection. The distortion of the current wave observed in Curve 22 is the result of having only one slot per pole per phase. It is similar to the sweeping forward of the magnetism in continuous-current generators, and with the two slots of the Parsons machine is less marked.

### § 7. Phase Swinging.

The influence of unequal turning moment in generators is a subject which in this section at least is somewhat stale. There is, however, an interest attaching to the following curves on account of the reversal of current. Fig. 26 was taken at Manors when two 500-kw. motor-generators were running light in parallel, but with no direct-current load, from a single generator at Neptune Bank driven by a marine-type triple-expansion engine.

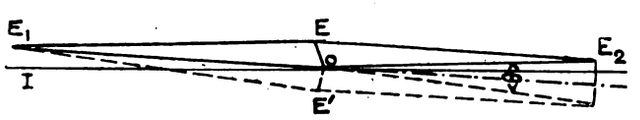

FIG. 27.—Generator Voltage Steady, Motor Swinging through Angle $\theta$.

The corresponding wave-form of the generator is Fig. 1 above. The voltage shows 5th and 13th harmonics, and was practically steady except for the small sliding movement of the ripples. The current wave presented the most remarkable appearance. It seemed a living thing, swinging as it did from one position (A) to the other (B) at 100 times a minute, the tops of the waves shooting out like tentacles. It is a very suggestive example of phase swinging, the more so because there is little sign of a lateral movement. The curves collapsed on themselves and sprang out in the reverse direction. To explain this, let O $E_1$, O $E_2$ (Fig. 27) represent the voltage vectors of a generator and synchronous motor respectively, running light with a power-factor nearly unity. The resultant voltage, O E, is therefore small. If now, by reason of the unsteadiness of the engine speed, the vector O $E_1$ is set swinging, the motor vector will follow, and if the disturbance is great, may swing past the zero line. As it approaches opposition to O $E_1$, O E falls to zero and increases to some opposite maximum O $E^1$ at the end of the swing. The steady position of O $E_2$ is usually above the zero line; the value O $E^1$ will therefore be less than O E. The current in the circuit is proportional to O E, and by inspection of the curves we see it diminish from a maximum, $I_1$, pass through zero, and increase to a lesser maximum, $I_2$. By measurement of Fig. 26 it is found that the relative angle of swing was six times the steady phase displacement between motor and generator; its absolute value cannot be determined from the curves. The power factor of the circuit was ·95. In the lower position (B) the 11th harmonic is prominent, and in the upper there is added to it—conspicuous at the maxima—a smaller 23rd or 25th.

### § 8. Phase Displacement and Load.

There is one more effect to which I wish briefly to refer. The measurement of the steady phase displacement between, say, two alternators in parallel, or a synchronous motor and its generator, depending upon excitation and load, has not hitherto been experimentally possible, though the general effect is well enough known. If a small white patch is placed on the side of one of the revolving poles of a synchronous motor, and this is illuminated by an arc alternating at the frequency of the circuit, the effect is a white line, but if it is observed through a fine slit cut in the edge of a disc driven by a small synchronous motor it appears stationary. On raising the excitation of the motor it moves forwards to a new position, and backwards if it is lowered, the amount of phase displacement corresponding to a change in either of the vectors O $E_1$ or O $E_2$. The great advantage of this new method is that it gives the actual movement of the rotor, and the influence of armature reaction in alternators in lowering the *generated* voltage can now be observed. For the O $E_1$ and O $E_2$ are not the terminal but the generated volts in the respective machines, and there is no phase displacement unless these change.

For the direct observance of phase swinging the method is very useful. When load is thrown on or off a motor or generator, the rotor appears to make torsional oscillations on the shaft, usually dying out in about half a minute. The time of oscillation at different excitations can be found, and the risk of hunting on any particular circuit determined. The fluctuation of current, and therefore of torque, by the variation of generator speed can also be readily seen. The arrangement is in effect an optical tachometer, and by the use of an enclosed revolving drum on which sensitised paper is mounted continuous photographic records could be obtained.

## PHYSICAL SOCIETY.

At the meeting of this society on March 10, Dr. R. T. Glazebrook, past-president, in the chair,

A paper on "**Direct-Reading Resistance Thermometers, with a Note on Composite Thermo-couples,**" was read by **Mr. A. Campbell.** The paper describes two methods by which the reading of a resistance box in connection with a platinum resistance thermometer gives directly the actual temperature without the use of any formula or table. In the first method the variable resistance in the measuring arm of the Wheatstone's bridge is shunted by a suitable resistance. When this shunt has the proper value, the change of resistance in the measuring arm necessary to give a balance is proportional to the change of temperature of the platinum to a good degree of accuracy up to 1,000deg. C. A more exact method—that of the "rectifying loop"—is somewhat similar. In it the measuring arm consists of a closed loop of resistance, one end of the arm being a fixed point on the loop, while the other end is a slide which can be moved along the loop. The total resistance of the arm is connected by a simple parabolic law with the excess, X, of the slider reading over a zero reading. Thus $R = A + BX + CX^2$. The author shows how the resistance of the loop and the zero reading may be calculated so as to make this parabolic formula identical with that giving the temperature resistance variation of any specimen of platinum. When the resistances have these values, the reading X will be proportional to the temperature (Centigrade) of the platinum. In an appendix the author points out that for measuring small temperature differences up to 100deg. or 150deg., the most useful thermo-couples are iron-nickel or iron-constantan. The voltages given by these are nearly, but not quite, proportional to the differences of temperature. In order to make the proportionality more exact, he proposes to use a "composite" (triple) junction by putting in parallel with one of the usual wires a wire of a third metal—*e.g.*, copper; by adjusting the relative resistances of the branches of this parallel circuit the temperature-voltage curve of the combination can be practically rectified.

**Mr. W. Duddell** expressed his interest in the paper, and asked the author if he had considered the question of putting a constant resistance in series with the rectifying loop. By so doing, it would be possible to simplify the mathematical processes involved in the method. With reference to the author's note on composite thermo-couples, he asked if Mr. Campbell could give any information regarding the variation of the thermo-electric properties of constantan with the percentage of nickel and copper present in the alloy.

**Prof. Callendar** said he admired the rectifying-loop method of reducing the direct readings to the gas scale, and thought it would be useful in practical work, especially at high temperatures, but for the most accurate scientific work at moderate temperatures he thought

Digitized by Google

the corrections would be too complicated, and that trouble would be saved by adopting the ordinary method. It was most important in practice to secure accurate compensation of the leads, which could be ensured in a satisfactory manner only by making the leads and the ratio arms equal. Instead of making the loop resistance equal to $k$ R, as proposed in the paper, it would be necessary to make it equal to R, and to write $x = c + m\,t$ or its equivalent. The method suggested by Mr. Duddell of adding to the loop a resistance in series equal to $R_0$ would simplify the algebraic relations of the coefficients, giving $m = a\,R_0$ and $n = a^2\,R_0/b$ but would prevent the thermometer reading on the loop below 0deg. C. For many purposes this would not matter seriously. Neither the loop method, nor the three lead arrangement subsequently proposed by the author, could be used with a bridge wire, as both involved plug or sliding contacts of negligible resistance. The three-lead arrangement also precluded the possibility of making an insulation test of the leads at any time. With regard to composite thermo-couples, he did not think the arrangement would be useful except for very moderate ranges of temperature on account of the irrationality of the curves, which could not be satisfactorily represented by parabolic formulæ. He had himself employed a similar arrangement with resistance thermometers, combining wires of different materials in series, such as platinum and gold, or platinum and iron, so as to eliminate the $b$ term. This was a simple and fairly reliable way of rectifying the curve, since the resistance variation of most metals followed approximately parabolic formulæ, and the sign of $b$ was positive for many metals but negative for platinum. It was difficult, however, to find a suitable metal capable of standing high temperatures without change.

**Dr. Chree** pointed out that the resistance of the coils and shunt would vary somewhat with temperature unless made of some material with a negligible temperature coefficient. This would presumably necessitate some correction to the reading in the ordinary case. He asked Mr. Campbell whether a change in the total resistance of the wire due to temperature affected in any way the accuracy of the calculations.

The **Chairman** expressed his interest in the paper and in the usefulness of the methods described for ordinary work, but pointed out that for the most accurate work it was advisable to work with the simplest possible form of apparatus and to apply the necessary corrections at the end. With regard to the question of compensation raised by Prof. Callendar, the mathematics given in the paper would embody his suggestion if $x_0$ were given a suitable value instead of being made equal to unity. The constantan wires referred to by Mr. Campbell had been tested over a large range of temperature, and it had been found that a constantan-iron couple gave a linear formula.

**Mr. Campbell**, in reply to Prof. Callendar, said it would be possible to arrange the rectifying loop with plug contacts instead of sliders; with 25 ohms in the measuring arm, sliders cannot cause serious error. In reply to Mr. Duddell's second question, he did not know if any of the other copper-nickel alloys gave better thermo-electric results (against iron) than constantan. In both of the rectifying methods the temperature coefficient of the measuring arm caused no more error than in the ordinary method. In further answer to Prof. Callendar's and Mr. Duddell's remarks, he mentioned that for both methods he had indicated clearly in the paper that when once the ratio of the resistances of the zero reading and the total loop (or the shunt) was found from $\alpha$ and $\beta$, then the absolute values of these resistances may be altered in any ratio desired. The bridge can thus have equal or unequal arms at will.

## TRADE NOTICES AND NOVELTIES.

### Gear Shield.

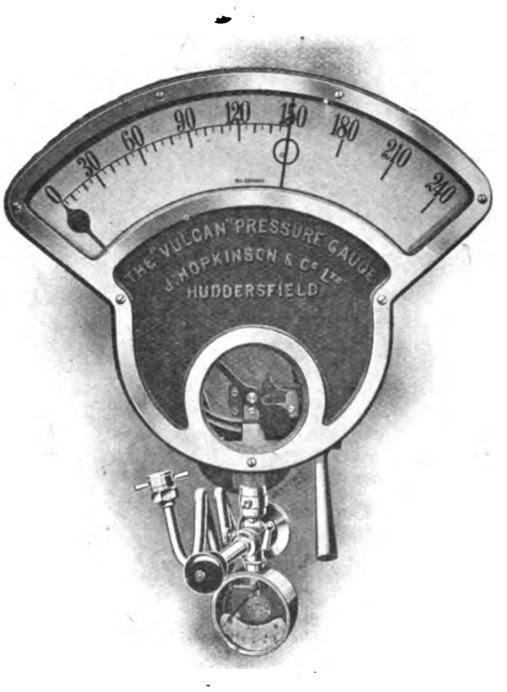
Mr. Fred. J. Down, M.I.E.E., 6, 7, and 8, Crutched-friars, London, E.C., calls our attention to a material called gear-shield, supplied by him for preventing wear on gears. It is claimed that gear-shield increases the life of gears by one-half or more, and makes them almost noiseless in working, acting as a cushion on the wearing surfaces and preventing metallic contact between the teeth. It contains no oil or grease and yet lubricates perfectly, effects great economies on tramway and railway motor gears, is largely used in American steel and iron work, and can be supplied in a slightly modified form for preserving steel and fibre ropes. Recent testimonials, of which we have copies, add considerable weight to these claims.

### Bevel-Edged Files.

From the makers, Messrs. Wright, Bindley, and Gell, Limited, Penistone-road, Sheffield, we recently received some particulars of their "Holderness" bevel-edged millsaw files. Each edge consists of three flat surfaces, thus enabling the teeth to be cut to a uniform depth. This, it is claimed, greatly prolongs the useful life of the files, and enables saws to be sharpened better and in less time than with the ordinary round-edged type of file.

### Hopkinson's "Vulcan" Sector Gauge.

Messrs. J. Hopkinson and Co., Limited, Huddersfield, are placing on the market a new and extremely novel form of steam-gauge and siphon. The "Vulcan" swivel siphon and pressure gauge is shown in the accompanying illustration, with the siphon disconnected and the pump attached for testing. The combination of gauge and siphon is designed to permit of the steam-gauge being tested with the boiler at rest. With this end in view the siphon is in the form of a copper coil with ample cooling surface, and can be easily detached and blown through without disturbing or in any way interfering with the gauge. This easy detachment of the coil forming the siphon is, then, one of the special features of the new arrangement, as it permits of the gauge being tested by a separate pump without dismounting the gauge. Further, the support for the gauge being independent of the coil, it follows that the weight of the gauge is a matter of indifference, and advantage is taken of this to use a sector-shaped gauge whose working parts are of unusually strong mechanical design. The combination can be swung round to any angle, which makes it possible to read a number of gauges from one position. The figures are marked on a white opal dial, and to make the reading at the working pressure more distinct, each increment up to the working pressure is marked, but beyond the dial is graduated for testing purposes only, in readings of, say, 40lb. As the dial is opaque, it can be illuminated from behind, and the position of the finger can therefore be readily distinguished at night or when the gauge is fixed in a dark place. As regards the siphon, this is made of the best high-pressure bronze, and fitted with Hopkinson's patent safety plug, the special feature of which is that the thread is not likely to be stripped by adjusting the packing nut, and it therefore cannot blow out. The "Vulcan" sector gauge should certainly prove very useful in electric lighting and power stations. Further particulars and illustrations of the instrument are contained in a pamphlet just issued by Messrs. J. Hopkinson and Co., Limited.



Hopkinson's Sector Gauge.

### Catalogues, etc., Received.

RADIATORS.—Numerous patterns of heat radiators, both of the luminous and Prometheus type, are illustrated in a list recently issued by the Sun Electrical Company, Limited, 118-120, Charing Cross-road, W.C.

HELLESEN'S DRY CELLS.—Hellesens Enke and V. Ludvigsen, Copenhagen, Denmark.

## INSTITUTION OF ELECTRICAL ENGINEERS.

The following candidates were elected at the extraordinary general meeting on March 9:

*Associate Members.*—W. T. Fraser, South Wales Electrical Power Distribution Company, Royal-chambers, Queen-street, Cardiff; R. C. Goldston, Tramway Depôt, Frost-hill, Liversedge, Yorks; C. L. Goolding, 335, Liverpool-road, Islington, N.; A. L. Hamkens, Byron House, 32 85, Fleet-street, E.C.; C. G. Hampson, Devonshire-avenue, Roundhay, Leeds; J. H. Hardy, Municipal Technical School, Halifax, G. W. O. Howe, M.Sc., 101, Victoria-avenue, Hull, Yorks; A. D. Jaffé, Strandtown, Belfast; E. G. Love, 20, St. Albans-avenue, Halifax; A. Press, 203-208, Temple-chambers, Temple-avenue, E.C.; J. R. Walker, 52, Hailsham-avenue, Streatham Hill, S.W.

*Students.*—F. C. Davies, The Laurels, Oakdale-road, Nether Edge, Sheffield; E. Graves, 12, Flodden-road, Camberwell, S.E.; M. Gregory, Ivy Cottage, Chequerhent, Bolton-le-Moors; P. F. Harris, Central Technical College, Exhibition-road, S.W.; G. J. Jackson, Westbourne, St. Annes-on-the-Sea; B. P. Walker, care of Messrs. Siemens Bros. and Co., Stafford.

## IMPROVED DRAWING APPLIANCES.

No apology need be made here for calling attention to a number of ingenious novelties designed by Prof. D. A. Low, and supplied by Messrs. Longmans, Green, and Co., 39, Paternoster-row, London, E.C., for use in connection with geometrical and mechanical drawing. The accompanying illustration (Fig. 1) shows a face view of a 60deg. set-square, and an enlarged cross-section of the sides of the frame. This set-square has a body of strong tough white wood, edged with transparent celluloid. It is framed and faced with thin white

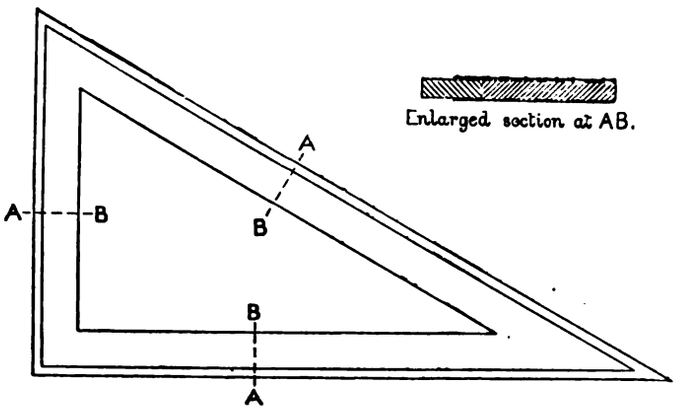

FIG. 1.

polished celluloid, and is exceedingly light and convenient to handle. Moreover, the faces which come in contact with the paper being smooth and white, any speck of ink or dust is at once seen and can easily be wiped or washed off. A special feature is that the thin celluloid facings leave off within about one-tenth of an inch of the drawing edges, so that when a square is resting on the drawing paper these edges stand above the paper to the extent of one-hundredth of an inch. This slight elevation above the paper does not interfere with accuracy in drawing, and it is found that in inking in it reduces very considerably the chances of blotting or smearing. Several sizes of tee-squares are made on the same principle. Fig. 2 illustrates an adjustable protractor set-square. This instrument consists of a right-angled

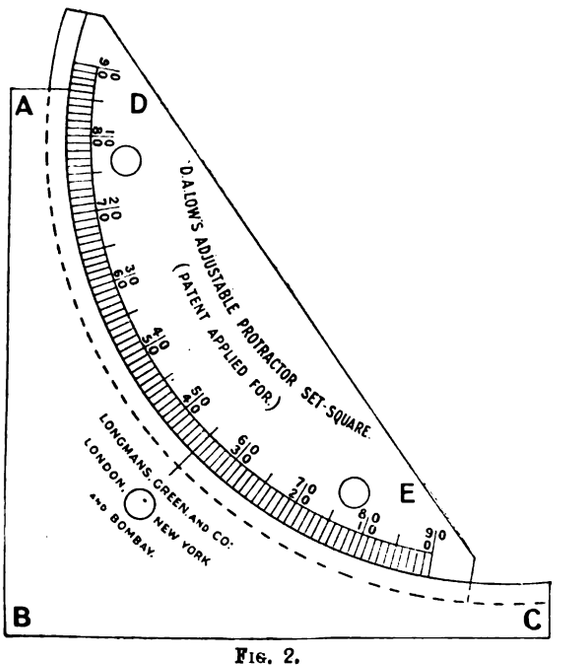

FIG. 2.

part, A B C, and a segmental part, D E, the circular edge of which has a tongue which fits into a corresponding groove on the part A B C as shown. The circular edge of D E is graduated in degrees, so that the straight or drawing edge may be set to any angle from 0deg. to 90deg., to A B or B C. The diameter of the protractor circle is 7in., and the edges A B and B C are about 4½in. long. The whole is made of white celluloid, and the total thickness is only one-sixteenth of an inch. Like an ordinary set-square, this instrument will be most generally used in conjunction with a straight-edge or tee-square. Our next illustration, Fig. 3, shows a vector set-square. This instrument consists of two arms, A B and B C, at right angles to one another, and a movable arm, D E, hinged to A B C. It is used in the same way as the adjustable protractor set-square already described, but has no protractor. Fig. 4 shows an instrument for measuring the areas of irregular figures, and specially useful for determining the mean effective pressure from indicator diagrams. It consists of a piece of clear transparent celluloid 6½in. long and 3in. wide, upon which is printed a series of equidistant longitudinal lines, intersected at right

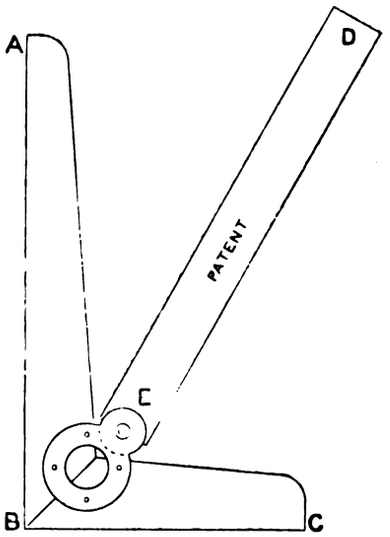

FIG. 3.

angles by a series of equidistant transverse lines. Very little practice with this instrument enables the mean effective pressure from an indicator diagram to be determined with sufficient accuracy for all practical purposes.

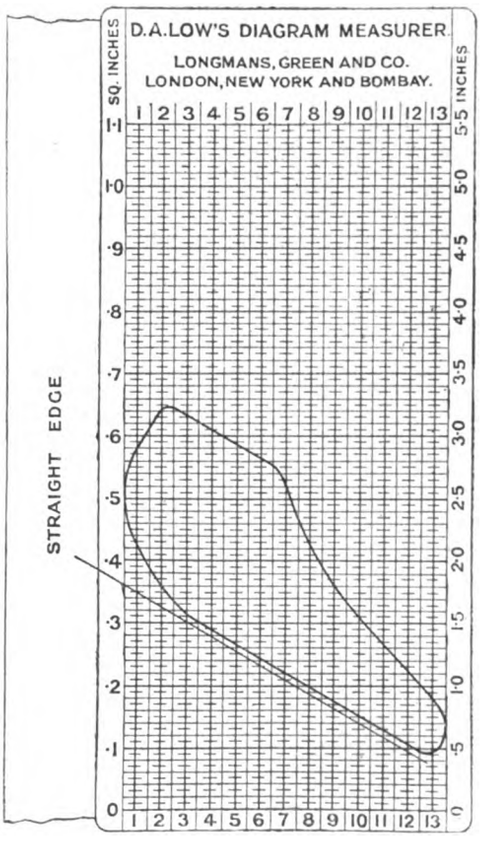

FIG. 4

Further particulars of the above-mentioned and other improved drawing appliances of the same class are contained in a descriptive pamphlet issued by Messrs. Longmans, Green, and Co. Samples of the instruments sent for our inspection are exceedingly well made, and we have no hesitation in recommending them to teachers, students, and draughtsmen.

## ELECTRICAL CONTRACTORS' CONFERENCE.

The members of the Electrical Contractors' Association had a conference in Glasgow, commencing on Monday night, 13th inst., and continuing throughout Tuesday, 14th. On Monday

Digitized by Google

evening the Glasgow local branch of the Scottish section of the association held their second annual dinner in the Grosvenor Restaurant, Glasgow, Mr. Thomas Wright being in the chair, and Messrs. Wm. McWhirter and W. C. Martin acting as croupiers. Among those present were Messrs. W. R. Rawlings, president of the association; E. L. Berry, chairman of the London section; McDermott, chairman of the Northern section; Finlay, chairman of Edinburgh section, etc.

Mr. E. G. TIDD, in proposing the toast of "The Electrical Contractors' Association, Glasgow Branch," said that this was the day of the great syndicate for the monopolising of particular industries - the day of the incorporation of particular trades for the achievement of their common aim. In the case of the electrical contractors, such an association was both necessary and desirable; necessary for the protection of the members of their profession from the various factors which tended to hamper them in their work, and desirable in so far as their meetings together gave increased facilities for that free exchange of ideas which was always so beneficial to technical men.

The CHAIRMAN, in reply, said that they were only the Scotch branch, but he thought they would be considered a very reliable and solid branch. He thought that they would be of great service not only to the trade in Scotland, but also to their friends in England. In 1900, they in Scotland formed an association of their own, first for social interests, then for trade interests, and, thirdly, to promote uniformity in regard to their methods of work. The first thing they had done after they came into existence was to meet with the manufacturers and try to come to an understanding with them. Three years later their English friends had done exactly the same thing. The manufacturers, however, were a very elusive body, and they found it difficult to get a hold of them. They were still trying, however, and had hopes of success. Another thing they had tried to do was get alongside the architects and the consulting engineers, but they had never been very successful with either of them. The grudge they had against these gentlemen was that while they (the electrical contractors) had to bear the responsibility of wiring installations properly, it very often happened that when they were nearing the end of their work they found that some third party had been called in to supply the fittings. In regard to municipal trading, they had had that to deal with also. There had been a moment of misunderstanding between the Electricity Committee and themselves, the former having thoughtlessly put clauses into a Bill that gave them almost unlimited power to do anything they liked in the way of wiring. The Electricity Committee thought that the electrical contractors were just going to become their own executioners, but being fair-minded men they at once took these clauses out when the matter was put properly before them. In a similar manner they had already instructed all their Scottish M.P.'s to vote against the pernicious London County Council Powers Bill. As an association they objected to municipal trading *in toto*. They objected as ratepayers to the men whom they sent to represent them using ratepayers' money to deprive these same ratepayers of their livelihood. They were resolved, therefore, to do all in their power to help their English friends in their present fight against municipal trading. As an association they were doing all they could to put a stop to cheap work. Much of this was still carried out in all their large cities, and the only way to get quit of it was to have higher ideals of how work ought to be done. To have their work well done with the best materials would be the best means of gaining and retaining the confidence of the public whom they served, as it would be the strongest argument against the municipal trader.

Bailie WILLOCK, in replying to the toast of "The Corporation of Glasgow," proposed by the CHAIRMAN, said that for the moment incandescent gas was likely to hold its own against electricity for street-lighting. For the lighting of side streets it could do more than hold its own. He hoped that they would set to work to bring about some improved device whereby street-lighting by electricity could compete with gas more effectively from the point of view of economy.

Mr. W. C. MARTIN proposed "The Chairman of the Association and Representatives from other Branches," to which Mr. Rawlings and Mr. McDermott replied.

Mr. RAWLINGS said that in London they were practically working along the same lines as those described by Mr. Wright. They were trying to get manufacturers to stop giving trade discounts to Tom, Dick, or Harry; and although the Manufacturers' Association had retired from the treaty which they had had with them, they believed that their efforts had been instrumental, to a great extent, in putting a stop to this evil. If the manufacturers did not come to terms with them he thought there would be but little doubt but that they would start their own supply house. With the Cablemakers' Association, he was glad to say, they had already come to a highly satisfactory arrangement. With regard to the London County Council Bill he was sure they would get it thrown out entirely.

Mr. MCDERMOTT also spoke.

"The Glasgow Corporation Electricity Department" was toasted by Mr. MCWHIRTER, who gave a brief sketch of the department's history, and spoke of the unfailing courtesy with which they were treated by the officials of that department. They regretted that it should have been necessary for Mr. Chamen to transfer his splendid abilities from the Corporation service to that of the firm of Messrs. Bramwell and Harris, but in Mr. Lackie the electricity department would have a worthy successor to Mr. Chamen as chief engineer.

Mr. LACKIE, in replying, said he could assure them that so long as they did their work well they need not fear the municipal trader. The electricity department recognised that the contractor and the undertaker were interdependent the one upon the other, and they in the electricity department tried to work accordingly.

The other toasts were "The Guests" and the "Chairman," proposed by Mr. R. D. LIVINGSTONE and Mr. J. M. DAVIES respectively.

On Tuesday various places of local interest to electrical men were visited, including the turbine steamer "Virginian," and the municipal buildings, where the Lord Provost (Sir John Ure Primrose) received the company. The Corporation power stations were also visited, and in the evening the members of the association were present by invitation at the meeting of the Glasgow Local Section of the Institution of Electrical Engineers, where a discussion took place on Mr. Lackie's paper on "Earthing."

## PERSONAL.

In succession to Mr. W. H. Willans, deceased, Mr. R. B. Martin, M.P., has been elected on the Board of the Notting Hill Electric Lighting Company, Limited.

The Whitby Urban District Council have appointed Mr. J. Hawes, 20, New Bridge-street, London, as assistant electrical engineer at a commencing salary of £104, rising by annual increases of £4 to £120 per annum.

The Swindon Town Council have appointed Mr. T. Medcalf traffic manager of the tramways.

The marriage of Chevalier G. Marconi (of Bologna) and Hon. B. O'Brien took place yesterday at St. George's, Hanover-square.

Mr. G. E. Smith, engineer and manager of the electric light works at Dartmouth, at a dinner given by him to the staff last week, on behalf of the staff presented his assistant, Mr. H. C. Babb, with a handsome writing case, as a token of the esteem in which he is held, and Mr. Babb, in his turn, presented the manager with a case of pipes on behalf of the staff.

The Leicester Corporation Tramways Committee have increased the salary of the chief electrical engineer, Mr. T. R. Smith, from £250 to £300 for the present year, and to £350 at the beginning of next year. The salary of Mr. T. Tyson, chief assistant engineer, has also been increased from £160 to £200 per annum, dating from Jan. 1, 1905.

## APPOINTMENTS VACANT.

**Chief Electrical Engineer**, Bermondsey Borough Council.

**Chief Draughtsman**, Bombay, Baroda, and Central India Railway Company (carriage and wagon department). Salary, Rs.250, rising to Rs.300 per calendar month. Particulars may be obtained from Mr. T. W. Wood, secretary, Gloucester House, Bishopsgate-street Without, London, E.C. Applications by March 22.

# LEGAL INTELLIGENCE.

### AUTOMATIC TELEPHONE COMPANY v. MARGOWSKI.

Mr. Justice Walton on Tuesday granted the defendant a stay of execution for 10 days, on condition that if an appeal was entered in the meantime £100 should be paid as security for costs. He gave defendant permission to see the documents without taking them out of the custody of the court.

### GREAT NORTHERN AND CITY RAILWAY.

In the King's Bench Division on the 10th inst., before Mr. Justice Lawrance and a special jury, Mrs. Stockton, Mrs. Arnold, and Miss O'Brien, three sisters, recovered £2,000 as compensation for structural damage caused to their residence, 20, Highbury-crescent, by the construction of the Great Northern and City Railway Company's tube.

### STATION UNDER A CHURCH.

Mr. Justice Farwell on Tuesday, on an application of the Ecclesiastical Commissioners, made an order for the payment of a sum of £170,000 Indian stock paid into court by the City and South London Railway Company for the right of making a station under St. Mary Woolnoth Church, at the top of Cornhill, E.C.

**Mr. George Borthwick**, for the Ecclesiastical Commissioners, explained that the company were authorised to make an underground electric railway and to take the church and certain adjoining lands. That Act of 1893 was qualified in 1896, and provision was then made that the railway company should not take any part of the church forming part of the property, but they might purchase, take, and use

Digitized by Google

the surface of the other part of the land, and might acquire an easement, with the right of using the subsoil under the church. This they did, and the church was supported by a steel plate.

**Mr. P. B. Abraham** said the railway company had been authorised to take the church, and afterwards certain learned bodies, which had nothing whatever to do with the matter, discovered that it was a very wonderful church, which ought not to be destroyed, and in consequence of their petition Parliament gave instructions to a committee to try and make some arrangement by which the church could be saved. The result was the provisions alluded to in the Act of 1896. The church had been preserved without breaking even a pane of glass. The company had spent £30,000 to £40,000 in making supports for the church, and had given it back in a much better condition than it was before. The cost of making the tunnel and station, 120ft. below the church, was £136,000. The intention of Parliament was not to put the company into a different position, but simply to oblige certain learned bodies who had no interest in the question. The company bowed to the decision, and had nothing more to do with the matter. He thought they had paid sufficiently for what they had got.

## TEMPORARY TRAMRAILS.

On Friday, at the King's Bench Division, Mr. Justice Lawrance and a special jury gave £860 damages to James Beale, a fishmonger, of York-road, Battersea, against Messrs. W. Griffiths and Co., for personal injuries sustained by the upsetting of a vehicle, caused, as he alleged, by the temporary rails laid in connection with the Southwark electric tramways not being properly laid and secured.

Mr. Clavell Salter, K.C., and Mr. Clarke Hall appeared for the plaintiff, and Mr. M'Call, K.C., and Mr. Crawford for the defendants.

## THE UNDERGROUND TELEGRAPH CABLES DISPUTE.

In Hamilton Sheriff Court on the 8th inst., Sheriff Thomson heard parties on a note by the Lord Advocate to the Sheriff to have decided the difference which has arisen between the Postmaster-General and the District Committee of the Middle Ward of Lanarkshire in connection with the laying of the underground telegraph cable from London to Glasgow in the highway at Bothwell. Recently an action of interdict was raised by the Middle Ward Committee against the Lord Advocate and the Postmaster-General, the question between the parties being as to the position in which the telegraph cable pipes should be laid, while that under the note is as to whether or not a difference has arisen which should be decided by the Sheriff or settled by an action in court. Mr. Henry Johnstone, K.C., with whom was Mr. J. C. Pitman, advocate, appeared for the Lord Advocate, and Mr. A. P. Smith, writer, Hamilton, appeared for the Middle Ward Committee. After a debate lasting over two hours, the Sheriff made avizandum.—*The Scotsman.*

## TRAMWAY COLLISION.

At Dudley County Court, on Monday, before Judge Howland Roberts, the Dudley, Stourbridge, and District Electric Traction Company, Limited, brought an action against the London and North-Western Railway Company to recover £1. 9s. 1d. in respect of damages to an electric car, caused through a collision of one of the company's cars with a van belonging to defendant company. It appears that the motorman admitted that the car was travelling at a greater speed than was allowed, and his Honour gave a verdict for the defendant company.

## SWANSEA TELEPHONES.

At Swansea County Court on Tuesday the National Telephone Company sued Richard Wilson, Hawarden-buildings, Treharne-road, Landore, butcher, for £4. 16*s.* 6d. in respect of two 10-party lines rental. Mr. Philips (Ingledew, Son, and Philips) was for plaintiffs, and Mr. Stobo Andrews defended.

**Mr. Philips** said he was suing under a guarantee to pay rent.

**Mr. Andrews** objected to the action for rent, as no instruments had been placed or wires run. He submitted the guarantee could only come into effect once the instruments were placed, or they had refused to let them carry out the contract. If that was right, defendant had committed a breach of contract. The company could not charge rent until the instrument was there.

**His Honour** held they could, as they had signified they were ready to carry out the work. According to the agreement, defendant made himself liable to pay rent as soon as the company gave notice they were prepared to put the telephone in. That notice had been given, but it was not reasonable to ask a tradesman to wait nine months before they began making arrangements. There would be judgment for the defendant, with costs.

# COMPANIES' MEETINGS AND REPORTS

## BROMPTON AND KENSINGTON ELECTRICITY SUPPLY.

The directors' report for the year ended Dec. 31, 1904, states that the revenue account shows a credit balance of £28,270. 12*s.* 7d., which, with the balance of £4,179. 8*s.* 1d. brought forward, £384. 2s. 11d. balance of interest received, and £109. 18s. surplus on sale of securities, makes a total of £32,944. 1s. 7d. After deducting £2 096. 10s. 1d. for interim dividend on the 7 per cent. cumulative preference shares, and £6,303. 14s. 7d. interim dividend at the rate of 9 per cent. per annum for the half-year to June 30 on the ordinary shares, the directors recommend that the sum remaining — viz., £24,543. 16s. 11d.—be dealt with as follows: to credit of depreciation account, £8,000; to payment of dividend on the preference shares for half-year ended Dec. 31, £1,909. 19s. 4d.; to payment of dividend on the ordinary shares for half-year ended Dec. 31 at the rate of 11 per cent. per annum, making 10 per cent. for the year, £7,973. 4s. 1d.; to directors' additional remuneration, £676 9s. 4d.; leaving to be carried forward a balance of £5,984. 4s. 2d. Owing to the price per unit having been reduced, whereby the consumers have benefited to the extent of nearly £4,000, the profits show a slight decrease for the first time in the history of the Company.

## BOURNEMOUTH AND POOLE ELECTRICITY SUPPLY.

The report of the directors for the year ended Dec. 31, 1904, states that the capital expended during the year under review amounted to £31,404. 18s. 5d., making the total expenditure at Dec. 31 last £318,294. 9s. 8d. In December last the balance of the ordinary shares was allotted *pro rata* to the shareholders at a premium of £1 per share, and the balance of the debenture stock was disposed of at par. In order to provide further funds as necessity arises for the development of the Company's business, the directors propose to increase the share capital of the Company from £300,000 to £500,000 by the creation of a further 10,000 preference shares of £10 each, and a further 10,000 ordinary shares of £10 each. The directors also propose to increase the borrowing powers of the Company from £150,000 to £300,000. The balance to credit of net revenue account is £15,764. 13s. 9d. This is arrived at by deducting from the balance brought forward from last year the final dividends on the 4½ per cent. and 6 per cent. preference shares, and the dividend for the year on the ordinary shares; adding the balance from this year's revenue account and deducting all interest charges and reserves for redemption funds. Out of the above-mentioned balance of £15,764. 13s. 9d. the full dividends for the year on the 4½ per cent. and 6 per cent. preference shares to Dec. 31, 1904, have been paid, and the directors now recommend the payment of a dividend on the ordinary shares of the Company at the rate of 7 per cent. per annum for the year ended Dec. 31 last. This will absorb £14,721. 13s. 3d. and leave a balance of £1,043. 0s. 6d. to be carried forward. Application has been made to the Board of Trade, with the consent of the local authorities concerned, for a provisional order for Wimborne and the surrounding districts, with a view to supplying same from the Company's station in the Bourne Valley. The total applications received at Dec. 31 last amounted to the equivalent of 121,589 8-c.p. lamps, being an increase of 21,051 for the year, as compared with an increase for the previous year of 19,542. The total number of Board of Trade units sold for lighting, power, and traction purposes was 1,703,329, being an increase of 183,327 units for the year. The Richmond (Surrey) Electric Light and Power Company, Limited, continues to make satisfactory progress. A dividend at the rate of 7 per cent. has been declared on the ordinary shares of that Company in respect of the year ended Dec. 31 last.

## LONDON ELECTRIC SUPPLY.

**Mr. Robert H. Benson,** presiding at the annual meeting on Feb. 23, expressed great regret at the absence of Lord Crawford, who, as usual, was obliged to spend the winter abroad. After referring with satisfaction to the strong cash position of the Company and to their unused capital powers, he concluded by moving the adoption of the report, which appeared in our issue of Feb. 17, and the payment of the dividends recommended.

**Sir W. H. Preece** seconded the motion.

**Mr. R. Stewart Bain** (the managing director) stated that during the year they completed a new trunk main route from their Blackfriars station to their Trafalgar station, *via* Westminster Bridge, thus giving them two routes, the other route being across Charing Cross Bridge. The average price received per unit sold still showed a decrease, and, owing to increased competition, the decrease was likely to continue. The cost per unit sold showed a decrease of no less than 50 per cent., owing to the large increase in their units sold and to the economy effected in their generation costs by means of their condensing plant. The increase in the efficiency of their system still continued. The prospects for the present year were distinctly favourable.

The motion was unanimously adopted.

## HARROW ELECTRIC LIGHT AND POWER.

**Mr. J. N. Stuart,** chairman of the Company, occupied the chair at the annual meeting on March 9. A report was carried in which was shown that, notwithstanding a great reduction in price, as shown by a comparison of the average price obtained in the two years—namely, 6·25d. in 1904 as against 7·28 in 1903, or nearly 14 per cent.—there was a surplus of £3,099. 13*s.* 8d. carried to net revenue account. The amount at credit of the latter account including £387. 12s. 3d. brought forward from 1903 amounts to £2,600. 17s. 4d., after payment of debenture and other interest and the interim dividend on preference shares. Out of this sum the directors have decided to transfer to depreciation account an additional sum of £944, the balance shown in last year's accounts as the deficiency in that account for past years, and to recommend the payment of the following dividends: final preference dividend, £365. 18s. 6d.; dividend on ordinary shares at 4 per cent., £1,051. 18s. 6d.; leaving a balance to carry forward of £239. 0s. 4d. The growth of consumption has responded to the reduction in price, the number of new lamps being 3,381, against 1,769 in 1903, and the number of units consumed having increased by 30,371 to a total o 259,833. The working expenses again show a reduction, the works

Digitized by Google

costs to 1·66d. per unit against 1·87d. in 1903 and 2·24d. in 1902. The total costs amount to 2·61d. per unit in 1904, against 2·87d. in 1903, and 3·43d. in 1902. A considerable sum, amounting to £4,745. 2s. 9d., has been spent on capital account, for condenser and superheaters (which were in use only partially towards the end of the year, so that the full benefit of the plant will not be felt until in the ensuing year) as well as for additional mains, meters, etc. The directors issued fresh capital during the year to the extent of £1 910, which they consider sufficient for the present requirements of the company.

## SCARBOROUGH ELECTRIC LIGHT.

**Mr. J. E. Ellis, M.P.**, who presided at the last general meeting, said the amount spent on capital account during the year amounted to no less a sum than £16,368. That was a very large sum for so small a concern, and for a district which comprised a comparatively small number of inhabitants. About 75 per cent. of the £16,000 had been spent on tramway plant, about 15 per cent. had gone in new improvements in the works for lighting and for things of that kind, and the remaining 10 per cent. was due to the acquisition of a field adjoining the works for possible extensions, and completion of the offices in York-place. On the credit side they had received during the year £10,426, which was, of course, a very much less sum than they had spent. Turning to the revenue account, they would see that on the debtor side £8,476 represented the outlay, and on the credit side they had a sum of £13,230, leaving a balance of £4,754. On the credit side of the revenue account occurred an item of £1,001 derived from premiums. The result of the year's working was that, after placing £1,500 to depreciation, they had a net divisible balance of £5,648. The directors recommended that a dividend be paid of 6 per cent., which would absorb £5,143, and leave a balance to be carried forward of £505. That was a larger balance than usual. They might have made the dividend a little higher, but they thought it advisable not to do so, because no one could tell what effect the lowering of the charges would have, and there were other reasons why it was better to carry forward a substantial balance.

The report and a dividend of 6 per cent. were adopted, and Mr. J. E. Ellis was re-elected chairman.

## WESTMINSTER ELECTRIC SUPPLY.

**Mr. Boulnois, M.P.**, who presided at the last general meeting, stated that the supply of current had increased to an equivalent of 711,679 lamps. He referred to the Administrative County of London Electric Power Bill, and thought it was hard that such an attempt should be made to oust companies in London who had borne the burden and heat of the day and to allow this company to come in and pick up the plums. By the irony of fate they were being assisted in opposing the Bill by the London County Council and the municipalities. The whole of the companies in London, with one exception, were also opposed to it. The Westminster Company would give most strenuous opposition.

**Mr. Hayes Fisher, M.P.**, seconded the adoption of the report (which appeared in our issue of Feb. 17), and it was carried.

A dividend of 15 per cent. for the half-year, making a total of 14 per cent. for the year, was declared.

## METROPOLITAN ELECTRIC SUPPLY.

The eighteenth ordinary general meeting was held on Tuesday at Winchester House. Mr. W. Harrison Cripps presided. The report (which appeared in our columns on March 10) and dividends equal to 10 per cent. per annum on the £10 ordinary shares, were carried.

An extraordinary general meeting was held subsequently, when resolutions were passed—on the motion of the Chairman, seconded by Mr. J. Carr-Saunders—for dividing each of the £10 ordinary shares into two shares of £5, and for doubling the number of votes attaching to the preference shares in order to preserve the relative voting power between the two classes of shareholders.

## HART ACCUMULATOR.

At the sixth ordinary general meeting of the Hart Accumulator Company, Limited, Mr. G. W. Kidd, the chairman of the Company, presided.

The **Chairman**, in moving the adoption of the report (which appeared in our issue of Feb. 25, and which was carried), congratulated the shareholders on another successful year's business, in spite of keener competition and general depression of the trade.

A dividend of 12½ per cent., less income tax, on the issued ordinary capital of the Company was carried.

## OLDHAM, ASHTON, AND HYDE ELECTRIC TRAMWAY.

The report (which is to be presented to the meeting to-day) shows a total of £29,349 and an expenditure of £22,877. The directors propose placing to depreciation and reserve fund £1,000, and after paying a dividend on the ordinary shares at the rate of 7 per cent. per annum for the six months ended Dec. 31, 1904, making 6 per cent. for the year, leave to be carried forward £142.

## SOUTH METROPOLITAN ELECTRIC LIGHT.

At the last general meeting of this Company Mr. Henry St. John Winkworth (deputy-chairman) presided, in the absence, owing to ill-health, of the chairman, Sir John Willox. The report (which appeared in our issue of Feb. 25) was carried. A dividend on the ordinary shares at the rate of 15 per cent., making 12½ per cent. for the year, was carried.

Mr. Percy Randall was re-elected a director, and the auditors Messrs. Deloitte, Dever, Griffiths, and Co., having been reappointed, a vote of thanks to the chairman, directors, and staff closed the proceedings.

## NORTHALLERTON ELECTRIC LIGHT AND POWER.

Mr. John Hutton, M.P., who presided at the annual meeting on the 22nd ult., said that they had made substantial progress during the past year. The balance-sheet (which was adopted) showed that they had sold 1,033 more units this year.

## CITY OF LONDON ELECTRIC.

**Mr. Joseph B. Braithwaite, jun.**, who presided at the annual meeting of the 8th inst., said that Mr. Herring's forecast last year that he hoped an additional dividend would be possible this year had been borne out. The result was mainly due to the exertions of the engineering staff, who had succeeded in still further reducing the cost of manufacture of electricity.

The **Chairman** then moved and **Mr. Frederick W. Reynolds** seconded the adoption of the report, which appeared in our columns on March 3.

It was stated that, with the exception of a small piece of ground which they held on a 999 years' lease, the property which they possessed at Southwark, where their generating station was erected, was all freehold.

## SOUTH LONDON ELECTRIC SUPPLY.

Mr. George Ellis presided at the annual meeting on the 10th inst., and said that the expectation expressed at their last annual meeting as to the probable increase in lamps connected had been fulfilled, the exact number on Dec. 31, 1904, being 107,000. Since then a large number of additional lamps had been connected to the mains and applied for, there still remaining a balance of nearly 7,000 lamps of 8 c.p. awaiting connection.

The report (which appeared in our issue of the 10th) was adopted.

## NATIONAL ELECTRIC CONSTRUCTION.

The report of the directors to Dec. 31, 1904, states that the gross profit for the period under review is £29,351. 3s. 1d., from which has to be deducted expenses of administration, allowances on contracts, etc., amounting to £9,411. 15s. 1d., leaving a balance of £19,939. 8s. From this has to be deducted the balance carried forwarded at Dec. 31, 1903—viz., £3,537. 10s. 4d.—leaving a credit balance of £16,401. 17s. 8d. The directors recommend that this amount be dealt with as follows: provision for reserves, depreciation, etc., as set forth in the profit and loss account, £10,111. 18s. 5d.; dividend at the rate of 6 per cent. on paid-up capital for the year, £6,007. 4s.; dividend at the rate of 1½ per cent. on vendors' shares, £282. 15s. 3d. The inauguration of the Musselburgh tramways and lighting undertaking took place on Dec. 12, 1904, and from that date to March 9 425,334 passengers have been carried by the tramways, receipts being £2,181. 8s. 3d. These returns have been obtained during the winter months, and should be considerably improved upon during the summer months. With regard to the lighting, applications for over 4,000 8-c.p. lamps have been received, the majority of which have been connected to the mains for some time past. These results are very satisfactory and the directors look upon the Company's holding in the Musselburgh Construction Syndicate as a valuable asset. The inauguration of the Bo'ness electric light undertaking took place on Feb. 6, and that of the Carnarvon undertaking on Feb. 23 of this year. The directors are satisfied with the applications for current received so far.

## ERNEST F. MOY, LIMITED.

The report of the directors for the 12 months ended Dec. 31, 1904, show that a profit of £831. 4s. 7d. has been earned during the year, which, together with the amount of £71. 8s. 7d. brought forward from last year, makes £902. 13s. 2d. available for disposal, and the directors recommend that this be dealt with as follows: 7½ per cent. dividend on ordinary shares, £588. 2s. 5d.; 6 per cent. dividend on preference shares, £80. 12s. 8d.; income tax on profit £831. 4s. 7d., £41. 11s. 3d.; general reserve account, £100; and that the balance of £92. 6s. 10d. be carried forward to next year's account.

## NEW COMPANIES REGISTERED.

**London Power Omnibus Company, Limited.**—Capital, £200,000. Object: to carry on the business of proprietors of motor omnibuses, other public or private conveyances of any description, whether driven or hauled by petrol, steam, electric, or other motive power. Registered office: 5, Copthall-buildings, E.C.

**Moter Omnibus and Wagon Company, Limited.**—Capital, £100,000. Objects: to acquire and carry out certain contracts relating to the construction, working, and dealing with motor omnibuses and other motor vehicles, whether worked by mechanical, animal, or other power. Registered office: 79, Salisbury House, E.C.

### Liens Registered.

**Llangollen and District Electric Light and Power Company, Limited.**—A debenture, dated Feb. 4, 1905, and a mortgage of even

Digitized by Google

date (by way of collateral security), to secure £1,000, has been registered. Property charged: by debenture—the company's undertaking and property, present and future, including uncalled capital; by mortgage—certain leasehold premises. Holder: S. L. Jones, Glanrafon, Llangollen.

**Central Electric Supply Company, Limited, London, W.**—Acknowledgment of indebtedness registered March 7, creating £50,000 4 per cent. debenture stock, making, with £300,000 already created, a total of £350,000 debenture stock, supplemental to a trust deed dated July 2, 1901, for securing a sum not exceeding £500,000; also instrument of charge under the Land Transfer Acts registered March 7, for securing £55 000 with respect to the above £50,000 of stock. Trustees: Hon. A. Lyttelton, K.C., 3, Paper-buildings, Temple, E.C., and W. H. Fisher, M.P. Charged on the undertaking and all the property and assets, present and future.

**Direct Spanish Telegraph Company, Limited, London, E.C.** Lien registered March 8, for £20,000 4½ per cent. debentures. No trustees. Charged on the undertaking and all the property, present and future.

**Gloucestershire Electric Power Syndicate, Limited.**—Issue on Feb. 22 of £850 debentures, part of a series created same date, to secure £1,500, charged on the company's undertaking and property, present and future, including uncalled capital. Holders: H. C. Smith, 222, Ditchling-road, Brighton; N. P. W. Brady, 7, St. Helen's-place, E.C.; D. MacKinnon, 23, Great Winchester-street, E.C.; Sir James Mackay, G.C.M.G., K.C.I.E., 9, Throgmorton-avenue, E.C.; Sir George S. Mackenzie, K.C.M.G., C.B., and S. Hall, 25, Great Winchester-street, E.C.; Sir William H. Marling, Bart, and W. J. P. Marling, Stanley Park, Stroud, Glos.; G. L. Addenbrooke, 53, Victoria-street, S.W.; F. Winterbotham, 5, Rowcroft, Stroud; P. Still, 15, Cadogan-gardens, S.W. and C. Bathurst, jun., 3, Stone-buildings, Lincoln's-inn, W.C. No trustees.

**Malaga Electricity Company, Limited.**—Re-issue on Feb. 14 of £16,034 debentures, part of a series created by resolutions of March 29, 1897, Feb. 7 and 28, 1898, and Oct. 13 and 20, 1899, to secure £50,000, charged on the company's undertaking and property, present and future, including uncalled capital, and the electrical station at Malaga. No trustees. Total amount previously issued of same series, £44,738.

**Kent Electric Power Syndicate, Limited.**—A memorandum of satisfaction in full of a charge, dated April 9, 1904, securing £1,000 has been filed.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Manchester.**—The Corporation require tenders for switchboards. Tenders by April 4.

**Hoylake.**—The Council invite tenders for 250-kw. steam alternator, with piping, etc. Tenders by March 21.

**Hornsey.**—The Town Council require tenders for cables, meters, junction boxes, etc. Tenders by March 27.

**Cartagena.**—The Public Works Department, Madrid, require tenders for electrification of the local tramways.

**Sofia.**—The District Finance Commissioners require 15,000 insulators, elements for batteries, etc. Tenders by April 3.

**Christiania.**—The Post and Telegraph Department require tenders for 8,000 kilos. of ¼mm. bronze wire. Tenders by April 10.

**Salford.**—The Corporation invite tenders for the wiring of the new Council school, Liverpool-street, Seedley. Tenders by March 31. See advertisement.

**Bucharest.**—The Post and Telegraph Department require tenders for 13,000 kilos 3mm. bronze wire and 120 kilos 1½mm. copper wire. Tenders by March 29.

**Bradford.**—The Corporation invite tenders for 2,500 kw. of motor-generators or rotary transformers. Tenders by March 30. Full particulars in our advertisement columns.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Norwich.**—The Corporation require tenders for rubber-covered wires and accessories, underground cables, and incandescent lamps. Tenders by March 20. See advertisement.

**Plymouth.**—The Corporation invite tenders for the supply of electricity meters, transformers, and cables (paper insulated). Tenders by March 18. See advertisement in last issue.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Madrid.**—The Post and Telegraph Department (Direccion de Telegrafos y. Correos), Madrid, require tenders for 65,000 insulators. Tenders by March 28. A deposit of 5 per cent. of the tender value is required.

**Keighley.**—The Electricity Committee invite tenders for the following plant: (Contract No. 9) one Lancashire boiler; (10) one 300-kw. direct-current steam dynamo, high-speed enclosed engine. Tenders by 10 a.m. on March 27.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station. Specification No. 619 may be obtained from the Government Railways Office, Brussels.

**Bucharest.**—The Post and Telegraph Department require tenders for 30,000 kilos iron plates, 30mm. by 8mm., 2,000 kilos ditto 30mm. by 9mm., 920 kilos 18mm. by 4mm., and 20,000 kilos 14mm. round iron staves. Tenders by March 21.

**Glasgow.**—The Trustees of the Clyde Navigation invite tenders for electric power generating and lighting plant for Clydebank Dock. Specifications, etc., may be obtained from Mr. T. R. Mackenzie, 16, Robertson-street, Glasgow. Tenders by April 10.

**Rathmines (Ireland).**—The Rathmines and Rathgar Urban District Council invite tenders for condensing plant. Specification, etc., may be obtained from Mr. George F. Pilditch, A.M.I.E.E., Electricity Works, Rathmines. Tenders by March 27.

**Swindon.**—The Corporation invite tenders for annual supply of incandescent and Nernst lamps; cables; fuse boxes, service boxes, and feeder pillars; lubricating oils and grease; and direct-current meters. Tenders by March 21. See advertisement in last issue.

**Birmingham.**—The Tramways Committee invite tenders for supply, delivery, and erection of 200 electric tramway cars. Conditions, specifications, etc., can be obtained from Mr. Alfred Baker, general manager, 254A, Corporation-street, Birmingham. Tenders by April 4.

**Madrid.**—Der Compania Electrica Madrilena de Traccion propose to extend their electric tramways from the Barquillo-street to Olivide-place. The concession for the works will be dealt with by the Public Works Department, Madrid, April 8. Tenderers for same must deposit a guarantee of £96.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Hammersmith.**—The Council invite tenders for the supply of boiler flues and economisers; high pressure steam-pipes; high-pressure feed-water pipes; exhaust steam, feed-water heater, and circulating-water pipes; steam-valves and feed-water heaters; and coal elevator. Tenders by April 5. See advertisement.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

## RESULTS OF TENDERS.

**Leicester.**—The Guardians have accepted the General Electric Company's tender for telephones.

**King's Lynn.**—The tender of the General Electric Company, at £1,998. 10s., has been accepted for a steam dynamo.

**Ilford.**—The Urban District Council have accepted the tender of the Western Electric Company, North Woolwich, at £1,750, for the supply of concentric armoured cable.

**Leith.**—Messrs. Bruce Peebles and Co., East Pilton, Edinburgh, have secured the order for a 600-kw. differentially-wound continuous-current dynamo and steam-engine.

**Ashton.**—The Town Council have accepted the tender of the Lancashire Electrical Engineering Company for the necessary steel-wire cable for the arc lamps in the market.

**Barnsley.**—Messrs. Monté-Callow and Co., 6, Ludgate-broadway, E.C., have obtained the contract for the supply of motor-starting switchgear to the Corporation for the ensuing year.

**Ilford.**—The Urban District Council have accepted the tender of Pullin and Shore, Boulton, at £1,100, for the installation of a telephone fire-alarm system on the double or metallic principle.

**Erith.**—The Urban District Council have accepted the estimate of Kelvin and James White, Limited, for the supply of the necessary electrical instruments for testing purposes at £124. 13s. 9d.

**Glasgow.**—The Corporation have accepted the tender of Grindley, Ross, and Co., 29, Commerce-street, Glasgow, at £487. 10s., for supplying and erecting electric light installation, etc., required in the new central police office.

**Leftwich.**—With reference to the recent contract for electric light at the Leftwich (Northwich) Isolation Hospital, we are informed that R. J. Nicholson and Co., of Manchester, have received an additional order for a complete system of telephones designed by them.

**City and South London Railway Co.**—The company have accepted the tender of Messrs. Walter Scott and Middleton for the construction of the extension of their line to Euston, *viâ* King's Cross, from their existing station at Islington, amounting to between £300,000 and £400,000.

**Lancashire Electric Power Co.**—Messrs. Bruce Peebles and Co., Limited, East Pilton, Edinburgh, have secured the contract for the supply of alternating-current motors of 15 h.p. and above to the Lancashire Electric Power Company for one year, for their hire-purchase and development department.

**West Ham.**—Messrs. Mountain and Gibson, Elton Fold Works, Bury, have obtained the contract for 55 improved double-deck trolley standards, with poles and heads complete, for the new cars of the West Ham Corporation tramways. The order has been placed through the Brush Electrical Engineering Company, who are building the car bodies.

**Leicester.**—The following tenders have been accepted: British Electrical Engineering Company, Limited, alternator £5,250, exciter £485, switchgear £350—£5,085; Hick, Hargreaves, and Co., Limited, set of engines for alternator, £4 855. In addition, the engineer estimates the cost of the foundations, etc., at £1,000, and a further £500 for steam and water connections, switches, cables, etc., making a total of £12,440.

**Manchester.**—Messrs. Bruce Peebles and Co., East Pilton, Edinburgh, have secured the order for three 590-kw. Peebles motor-converters, to be constructed on the Peebles-Bragstad-La Cour patent

Digitized by Google

system. These are to be installed in the Dickinson-street station of the Manchester Corporation electric supply, and will convert 6,500-volt three-phase current to low-tension continuous current direct without interposition of transformers.

**West London Tramways.**—Messrs. W. T. Henley's Telegraph Works Company, Limited, Blomfield-street, London-wall, E.C., have obtained from the London United Tramways Company the contract for the cable work in connection with the extension of the West London Tramways to Wimbledon, Surbiton, Kingston, etc. This contract, which is one of the largest ever placed for cables in connection with tramway work, includes about 30 miles of three-phase, 11,000 volt, extra high-tension cable, and about 45 miles of low-tension feeder, distributor, and telephone cables, etc.

**Ghent.**—The Municipality of Ghent have awarded the contract for the supply of 15 electric cranes to a Belgo-German firm, established in Belgium, for the mechanical parts, in co-operation with a Belgian firm for the electric motors and equipment. The contract price for each of the cranes, which are to be of half-arch construction, is £440 for the mechanical parts, £214 for the electrical equipment, and £99 for the lower and elevated rails therefor. This tender, £753, the lowest made, was rendered still more advantageous, when quickness of delivery and economy of working were taken into account.

# BUSINESS NOTES.

## TRACTION.

**Whitfield.**—It is expected that the electric cars from Salford will run through to Whitfield before Easter.

**Rawmarsh.**—The deposit with regard to the Mexborough and Swinton Tramways Extension Bill has been paid.

**Dartford.**—The Urban District Council have completed their arrangements for a loan of £93,000 for the construction of tramways.

**Sheffield.**—The Corporation have decided to extend their tramway lines to Firth Park. The present lines stop 372 yards short of that point.

**Southport.**—The Town Council intend to oppose the application for a Board of Trade order by the Ormskirk and Southport Light Railway.

**Erith.**—The report of the consulting engineers is to the effect that good progress is being made with the permanent way for the tramways.

**Bradford.**—The relaying of the Wyke tramway, the estimated cost of which is £17,000, will now be proceeded with as quickly as practicable.

**Croydon.**—The Croydon Chamber of Commerce have discussed the tramway question, and passed a resolution against any extension of the tramways.

**Newcastle-on-Tyne.**—The Tramways Committee of Newcastle Corporation have decided to extend the tramlines from Scotswood-road to Scotswood Bridge.

**Wakefield.**—The Wakefield and District Light Railway Company propose to double their existing single line from Wakefield (through Lupset and Horbury) to Ossett.

**Swansea.**—A few trial runs have been made with the electric cars, but there are still a few lengths of route to be completed before the whole system is ready for inspection.

**Dundee.**—On the advice of Mr. Richardson, the electrical engineer, the span-wire construction is being used to replace a number of poles in Reform-street. The span wires are supported from buildings on either side.

**Tarporley.**—The scheme to connect Tarporley and Mouldsworth by means of a light railway to run through Duddon and Ashton has been approved by the Light Railway Commissioners. Mr. Fergusson is the engineer for the scheme.

**Kilmarnock.**—The Town Council have agreed, in view of the success which had attended the electric tramway cars, that the line on the main route from King-street Church to Riccarton should be doubled at an expenditure of £3,200. The committee are to arrange for the purchase of three additional cars.

**Leeds.**—A scheme for equalising the stages on the Leeds tramways has been approved by the traffic manager of the Tramway Committee. The object of the scheme is to give a two-mile ride for 1d. on every route throughout the city. The principle of the scheme has already been sanctioned by the Town Council.

**District Railway.**—The employés of this company have been granted an interview with the full board of directors at which all points in connection with the proposed new rates of pay were discussed. The statement submitted by the deputation of employés is to be carefully considered by the directors.

**Warrington.**—After hearing before the Light Railway Commissioners, the Cheshire Light Railways, Limited, have withdrawn their application for powers to construct a light railway between Knutsford and Warrington. The opposition brought against the scheme is responsible for the withdrawal of the application.

**Dalkeith.**—Notices have been posted throughout the district from Nether Liberton to Dalkeith, and in Bonnyrigg and Lasswade, to the effect that application would be made to the Secretary for Scotland in April, 1905, for a provisional order to incorporate a company and to lay down and maintain tramways in the district in question.

**Great Western Railway Bill.**—The District Railway Company, the Great Northern, Piccadilly, and Brompton Railway, and the London United Tramways Company have been granted *locus standi* to be heard in opposition to the above Bill, which provides for the construction of some short lines of railway in the Ealing, Acton, and Uxbridge areas.

**Perth.**—A deputation from the Perth Tramway Committee has visited Ayr, Paisley, Motherwell, Glasgow, Dundee, and Kirkcaldy in order to obtain information as to the management and working of an electric service of cars. As a result the burgh electrical engineer has been appointed tramway manager at an increased salary. A traffic superintendent will be appointed.

**Woolwich.**—The Works Committee of the Woolwich Borough Council have considered a plan submitted by the borough engineers showing the proposed widening of Plumstead-road, High-street, and Bostall-hill to Basildon-road. If the widening be carried out, it will admit of a double line of trams being laid down throughout the route. The estimated expense of the proposed widening is £50,000.

**Blackrock.**—At a special meeting of the Urban District Council in committee for the purpose of considering the Dublin Tramways Bill of 1905, a telegram was read from Mr. J. J. Mooney, M.P., stating that he would move that a clause to give permission to the company to supply electric light to the township should be inserted in the Bill when it came before the House of Commons.

**Aberavon.**—On Wednesday last an enquiry was held by Lieut.-Colonel E. Druitt, R.E., with respect to the Aberavon district electric provisional tramway order, in order to ascertain whether the consent of the Glamorganshire County Council ought to be dispensed with. The questions raised were: (1) Did the town require the tramway? and (2) Did they object to the pavement accommodation being curtailed by 6in.? We understand that the Corporation supported the amended scheme, under which a bridge has to be widened by the company.

**Dewsbury.**—The British Electric Traction Company have given notice of their intention to apply to the Board of Trade for approval to the transfer of the portion of the undertaking authorised by the Spen Valley light railway orders, situated in the borough of Dewsbury, to the Dewsbury Corporation, and the remainder of the undertaking to the Yorkshire (Woollen District) Electric Tramways, Limited. The system extends from Ravensthorpe (*via* Dewsbury) to Oleckheaton, from Thornhill to Dewsbury, and from Heckmondwike to Dewsbury, and is some 15 miles in length.

**London County Council.**—It is proposed that the undertaking of the Woolwich and South-East London Tramway Company be transferred to the Council at midnight on March 31. A credit of £50,000 has been passed towards the whole of the purchase. It may be remembered that the Finance Committee reported on July 23, 1901, when the Council decided to take steps to acquire these tramways, that from a purely financial point of view it was at least doubtful whether the undertaking, if purchased, would pay its way, and that the purchase must therefore be justified upon the ground that it is required by the general policy of the Council.

**Motor 'Buses for Railways.**—Councillor Boyle, of Manchester, presided on Wednesday at a conference of representatives of the North-Eastern, Midland, and Great Western Railway Companies and the executive committee of the Municipal Tramways Association for the purpose of considering the clauses in the three companies' Bills in Parliament this session, under which the companies seek powers to run motor omnibuses in connection with their respective railways. These Bills have been blocked on the second reading. Suggestions were made to the companies' representatives that the clauses should be amended so that they be limited in their operations to 'buses running to and from the companies' stations.

**Glasgow.**—Sir James Thompson, speaking at the annual meeting in Glasgow of the Caledonian Railway, denounced the Glasgow Corporation for extending electric cars to the suburbs and to country places outside the city. Such competition, he said, was hurting the railways, and was not a legitimate form of municipal enterprise. It was a grave danger, as it induced the population to reside outside the city boundary and increased the burden of taxation upon those who remained. The Caledonian Railway Company was Glasgow's biggest ratepayer. He urged the shareholders in all enterprises to oppose electric car extensions. It would be better for the Caledonian Railway to meet this competition by electrifying their suburban lines.

**Accrington.**—The committee of the House of Commons have passed the Bill of the Accrington Corporation empowering the conversion of the Accrington tramlines for electrical working. The committee also gave the Corporation authority to supply electricity in the Church, Clayton, Oswaldtwistle, and Altham areas, but refused power as regarded Haslingden, and they stipulated that the Lancashire Electric Power Company shall not be obliged to obtain the consent of Accrington to the company entering the four areas named, while if competition does take place, the Corporation are not to be at liberty to cut down the prices for outside consumers to less than those charged in the borough. Other provisions in the Bill, of a sanitary character, were passed without opposition.

**Gorleston.**—The Town Council held a special meeting at the town hall last week to expedite arrangements for taking over the Gorleston and Southtown Tramways. The town clerk presented a report from the General Purposes Committee, which stated that the total amount of the arbitration award was £15,000, including the incidental costs which have to be borne by the Corporation. They recommended that application be made for the borrowing of a loan of £15,000 on the security of the borough rate, and that the Tramways Committee be empowered to do all that is necessary for the carrying out of the undertaking immediately after the purchase from the company is completed, a cheque to be drawn for the amount of the award as soon as the town clerk had made arrangements for taking over the concern. This was agreed to, and the work of electrification has since been commenced.

**Yarmouth.**—Messrs. Preece and Cardew, the Corporation's consulting engineers, have undertaken the supervision of the tramways

Digitized by Google

extensions. The tender of Mr. J. Tidman for the purchase of 360 tons of discarded rails at 40s. 7d. per ton has been accepted. No change is to be made at present in the hours and pay of the staff taken over from the company. The permanent staff are to receive half-pay during sickness for one month, their cases then to be reconsidered. On and after April 1 a charge of 1d. per package is to be made for passengers' luggage not taken inside the cars. A loan has been granted for £9,700 for the wood paving of Southtown-road, but the work is to be undertaken by the Tramways Committee at £8,700, the reduction of £1,000 being due to the lower of cost of jarrah blocks. It has also been agreed to pave with jarrah blocks High-street from the vicarage to the Memorial buildings, and to apply for a loan. The work will cost £1,360. The month's takings on the Yarmouth trams amounted to £254, an increase of £34.

**Railway Bills.**—The General Committee on Railway and Canal Bills met on Wednesday, and constituted the Railway and Tramway Bills which have been deposited for consideration during the present session into the following groups: Group 1.—Great Eastern, Great Northern and Great Western (New Railways) Railways. Group 2.—North-Eastern, North-Eastern (Steam Vessels), Midland and Rotherham, Maltby, and Laughton Railways. Group 3.—Aberdare Tramways, Great Western (Additional Powers), and London and North-Western Railways. Group 4.—Cork Junction Railway, Dublin United Tramways, Dublin, Wicklow, and Wexford, Great Northern (Ireland), and Midland and Mullingar, Kells, and Drogheda Railways. Group 5.—Charing Cross, Euston, and Hampstead, Edgware and Hampstead, Great Northern, Piccadilly, and Brompton (No. 1), and Baker-street and Waterloo Railways. Group 6.—London County Council (Tramways), London Southern Tramways, London United Tramways (Extension of Time), and Metropolitan Electric Tramways.

**London County Council.**—In connection with the sale of its undertaking to the London County Council, the Woolwich and South-East London Tramways Company claimed £57,206. The Council's valuation was £30 000. As a result of arbitration the purchase price has been fixed at £46,152. 3s. 1d., exclusive of harness materials, consumable stores, etc., which it has been arranged shall be taken over at a valuation at the date of the transfer of the undertaking on March 31. The Finance Committee point out that they reported in July, 1901, when the Council decided to take steps to acquire these tramways, that "from a purely financial point of view it was at least doubtful whether the undertaking, if purchased, would pay its way, and that the purchase must therefore be justified upon the ground that it is required by the general policy of the Council." After long delay and much debate the tramway scheme connecting Camberwell-green with Dulwich has at last been commenced. A large block of buildings at the end of Camberwell New-road has been demolished, and the lines are in progress which will enable the electric cars from the different bridges to pass up Denmark-hill and thence to Dulwich.

**Sunderland.**—The dispute between the Assessment Committee and the Corporation over the assessment of the electric tramway undertaking has been amicably settled at last. The following figures show that the Corporation have gained a decisive victory without taking legal action. The original valuation of the tramways for the year ending March, 1903, to which the Corporation objected, was based upon the receipts for that year, which were £59,284, and the amount of the assessment was £14,129. While the matter has been in dispute the figures for the year ending March, 1904, were obtained, and they gave the gross receipts as £62 597, and the assessment made on that return was £13,650. When the Corporation appealed to the Assessment Committee, that body offered to reduce the amount to £11,000, but the Corporation were far from satisfied with this offer, and hence the dispute. Now, however, the amount fixed, based upon the figures for the year ending March, 1904, is £7,653, and so the matter is settled without the Corporation having to take legal action. The Corporation also appealed to the Assessment Committee in respect of their electric lighting undertaking, and it is understood that negotiations are proceeding for a like settlement.

**London United Tramways.**—Messrs. J. G. White and Co., Limited, 22A, College-hill, Cannon-street, London, E.C., who have recently obtained the contract from the London United Tramways Co., amounting to about £165 000, supply the following particulars:—The contract with the London United Tramways comprises two distinct sections. The first is in Kingston, Surbiton, Malden, and Wimbledon districts. The following are the routes: Starting from a junction of London-road and Eden-street, the first route goes along Richmond-road as far as King's-road, and along King's-road to a terminus at the Kingston Gate of Richmond Park. The second route goes along London-road and Kingston-hill, terminating at George-road. The third route starts from a junction with the latter in London-road and goes along Cambridge-road, Kingston-road, Burlington-road, West Barnes-lane, and Coombe-lane, terminating near Raynes Park Station. The fourth route starts at Clarence-street, goes along Eden-street, St. James-road, Penrhyn-road, Kingston, Surbiton-crescent, Victoria-road, Portsmouth-road, and terminates at Winter's Bridge, Long Ditton. The fifth route starts with a junction with the latter in Victoria-road, Surbiton, goes along Victoria-road and Ewell-road, terminating at Red Lion-lane, Tolworth. The total route length of this line is about 10¼ miles, and the length of single track is about 18¾ miles. The second section is in Hanwell and Brentford, starting from a junction with existing tramways in High-street, Brentford, and then goes along Boston-road, Lower Boston-road, and joins existing tramway in High-street, Hanwell, with another branch going along Boston-road, and joining the same tramway in Broadway, Hanwell. The route length of these lines is about 2⅝ miles, and the length of single track 5½ miles. The type of construction of the track is particularly strong, and consists generally of No. 3 B.S. rails, with cross girders spaced 9ft. apart throughout, and the joints are supported by anchors of H section, secured to rails with bolts and clips. The concrete underbed is 6in. thick, finished off with a layer of 1in. fine concrete, and over this a floating coat of 1in. cement and sand to form bed for wood paving. The paving throughout is of jarrah wood, finished, in the Kingston section, with an edging of granite setts, while in the Hanwell and Brentford section the margins are entirely of granite setts. The overhead construction is span-wire throughout, the poles being 33ft. long, and the ornamental character of the remainder of the London United Tramways will be preserved on the new sections. The trolley wire will be 2/0 B. & S. gauge grooved copper wire, and will be supported by mechanical ears. The height of the trolley wire above rail level will be 23ft., which is greater than is usual, owing to special London conditions.

## LIGHTING AND GENERAL.

**Louth.**—The proposed electric lighting scheme has been rejected.

**New Address.**—Mr. J. R. Bell, M.I.C.E., has taken offices at 25, Victoria-street, Westminster.

**Glasgow.**—New wiring rules, to which we refer in another column, will come into force on May 1.

**Whitehaven.**—New instruments for testing consumers' wiring are to be purchased at a net cost of £18. 4s.

**Scalby.**—Arrangements have now been concluded for an extension of the National Telephone system to Scalby.

**Stafford.**—Permission has been granted to the National Telephone Company to lay an underground telephone pipe.

**Friern Barnet.**—The Council have granted an application from the Hornsey authorities to lay a short cable in their district.

**The Exchange Fire.**—Telephonic communication with the Bank Exchange, destroyed by fire on Feb. 28, has been restored.

**Gravesend.**—Application is to be made for sanction to borrow £4,814 for electricity works and £1,147 for a dust destructor.

**Bermondsey.**—The Council have agreed to an extension of the electric light mains and feeders at an estimated cost of £6,963.

**Kirkby-in-Ashfield.**—The question of a telephonic service for the district is being considered by a sub-committee and the postmaster.

**Barnsley.**—The Town Council have decided to extend their electricity works at a cost of £4,403, and will apply for the necessary loan.

**Arbroath.**—The negotiations with the Empire Company having failed, the whole matter of electric lighting has been referred to a committee.

**Loughborough.**—We understand that a report will be presented to the next monthly meeting of the Town Council recommending electric street-lighting.

**Barking.**—An enquiry has been held into an application of the Urban District Council for sanction to borrow £8,500 for purposes of electric lighting.

**Halifax.**—The electricity works are expected to show a surplus of about £3,000, a good proportion of which will be handed over for the relief of rates.

**Worksop.**—The Urban District Council have completed the loan for £1,000, the balance of the electric lighting loan sanctioned by the Local Government Board.

**Change of Address.**—The Electric Lighting and Traction Company of Australia, Limited, have removed their registered office to Finsbury Pavement House, London, E.C.

**Fulham.**—An expenditure of £245 is required for extension of electric lighting mains in Walham-grove, Elmstone-road, and Harbledown-road for public and private lighting.

**Gillingham.**—The engineer's last report shows that a total o 14,047 8-c.p. lamps, with 226 consumers, are now connected. A number of extensions are to be carried out.

**Bath.**—The Council have agreed to an application from the National Telephone Committee to erect 12 poles, subject to the exact position of each pole being approved by the surveyor.

**London Gazette.**—Frederick Stone, 47, Full-street, Derby, has been released from trusteeship in the estate of Harold Powell, electrical engineer, 47, Northumberland-street, Derby.

**Rosario Electric Co.**—The directors have declared an interim dividend of 3 per cent. for the half-year ended December 31, 1904, on the 6 per cent. cumulative preference shares of original issue (£5 each fully paid).

**Newport.**—The Electricity and Tramways Committee of the Corporation propose to apply for sanction to borrow a further sum of £12,500, repayable in 25 years, for electric lighting and power supply purposes.

**Yarmouth.**—A sum of £420 for lighting the Marine-parade North is to be provided out of the balance of the profits on the electricity undertaking, and £800 will be transferred to the credit of the general district rate.

**British Insulated and Helsby Cables.**—The directors recommend a dividend of 4 per cent. making 8 per cent. for 1904, placing £21,000 to depreciation, £5 000 to debenture redemption, £8,500 to special reserve, and carrying forward £7,100.

**Lichfield.**—The City Council have already consented to the provisional order which the Board of Trade propose to issue to Messrs. Foote and Milne, Limited, and have arranged for a protective clause to be inserted into the Shropshire and Worcestershire Electric Power Bill.

**Colne.**—The last report of the electricity works manager shows an increase of 970 in the units of electricity generated in February as compared with the corresponding month of last year. The consumers increased by 39. The promenade lighting scheme has been deferred.

Digitized by Google

**Stamford and Rutland.**—An exhibition of electrical plant, appliances, etc., promoted by the Urban Electric Supply Company, Limited, was opened on Monday at the Assembly Rooms by Mr. F. P. Rawson, of Sheffield, the proceeds being in aid of the Stamford and Rutland Infirmary.

**Ferranti Limited.**—We are informed that under the scheme of reconstruction the new company was incorporated on the 27th ult., and will as and from March 1 proceed to carry on the business as hitherto carried on by Messrs. A. W. Tait and Arthur Whittaker as receivers and managers.

**South Metropolitan Electric Light and Power Co.**—The debenture stock transfer register of this company will be closed from the 20th to 31st inst. (both days inclusive) for the preparation of the warrants for half-year's interest payable April 1 next, which will be posted on the 31st inst.

**Shrewsbury.**—The Council have sanctioned an expenditure of £5 295 to carry out necessary extensions at the electrical works, and have authorised the Electric Light Committee to petition Parliament, if necessary, against a Bill to be introduced by a company affecting Shropshire and Worcestershire.

**Cheltenham.**—Mr. Ley Wood, at the last Town Council meeting, described experiments with various kinds of Nernst lamps, and declared that the committee had arrived at the conclusion that it would be inadvisable to substitute Nernst for arc lamps, as the cost of the alteration would be from £3,000 to £3,600.

**Maidstone.**—An enquiry has been held into the application of the Town Council for sanction to borrow the sum of £6,000 for the electrical undertaking, made up as follows: coal station, £330; extension of mains, £3 703; indicators, £150; public lamps, etc., £620; additions to the switchboard, £550; new feeder in High-street, £550; contingencies, £97.

**Northern Counties Electricity Supply Co.**—The directors recommend a further dividend of 1½ per cent., making a total of 3 per cent. for 1904, placing £1,500 to reserve account, leaving £256 to be carried forward. It is proposed to offer to the shareholders the balance of the last issue of shares not yet taken up, and to make an issue of debentures.

**Agency.**—The Rhodes Electrical Manufacturing Company, Limited, have appointed Mr. P. A. Paris as their sole representative for Manchester, including the counties of Cheshire and Lancashire, for the sale of their direct and alternating current motors. His temporary address is 42, Yarburgh-street, Alexandra Park, Manchester (telegraphic address, "Rhodique, Manchester").

**Brompton and Kensington Electricity Supply Co.**—The report for 1904 shows an available balance of £32,944. The directors recommend a final dividend on the ordinary shares at the rate of 11 per cent. per annum, making 10 per cent. for the year. The sum of £8,000 is placed to depreciation account, £676 to directors' additional remuneration, and £5,084 is carried forward.

**Camborne.**—A six days' electrical exhibition is being held opposite the works of the Urban Electric Supply Company, Limited, Tuckingmill, in charge of the resident managing engineer, Mr. F. S. Hanning. The gross proceeds of the exhibition will be handed to the West Cornwall Miners' Hospital, the committee of which have decided to give 5 per cent. of the amount to each of the local nursing associations.

**Dublin.**—In proposing the electric lighting estimates on Tuesday, Mr. Irvin said they had provided absolutely for the interest and sinking fund upon a sum of £20,000 that would be spent a couple of months hence on the extension of the electric lighting in the old city area. They were now in a satisfactory position. This year the rates would not have to provide one penny to carry on the electric lighting of the city.

**Wireless Telegraphy.**—A Reuter's Tripoli telegram says the Turkish Government has given a concession to a well-known German firm to establish wireless telegraphy stations at Derna (Tripoli) and Rhodes. An engineer has arrived here in order to make arrangements for the installation. Telegraph communication with Constantinople will be established in May. This is the Tripoli on the coast of Syria, near Alexandrette.

**Longton.**—The Corporation find the use of electricity for motive power purposes gradually extending and coming into favour with manufacturers and tradesmen, and have decided to adopt the following reduced scale of charges for power: for 500 units per quarter or less, 2½d. per unit; above 500 units and under 1,000 per quarter, 2¼d. per unit; above 1,000 units and under 1,500, 2d. per unit; above 1,500 units and under 2,000, 1¾d. per unit.

**Calcium Carbide.**—New regulations have been made by the Austrian Ministries of the Interior, Commerce, Railways, and Agriculture regarding the production and use of acetylene, as well as the storage and transit of calcium carbide. These regulations can be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between the hours of 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

**Private Bills.**—The following Bills have been read a second time in the (1) House of Lords: Metropolitan Railway Bill. (2) House of Commons: Wigan Corporation, Bristol Corporation, L.C.C. (Tramways), Baker-street and Waterloo Railway, Charing Cross, Euston, and Hampstead Railway, Edgware and Hampstead Railway, Great Northern, Piccadilly, and Brompton Railway (No. 1), Ealing Corporation, and the Chelsea Electricity Supply Bills.

**Preston Assessment.**—The premises and mains of the National Electric Supply Company, Limited, of Preston, were some time since assessed at a rateable value of £4,609. The company thereupon decided to appeal against this amount, and on Mr. Humphreys Davies appearing before the Assessment Committee upon their behalf, a reduction of the rateable value to £4,000 was obtained, with an undertaking that this amount should not be disturbed for two years.

**Heckmondwike.**—The Standing Orders Committee of the House of Lords have passed the Heckmondwike Improvement Bill, by which the authorities sought to confer further powers on the Heckmondwike Urban District Council with regard to supply of water and electricity, and the improvement, health, local government, and finance of the district, etc. Clauses 10 and 11 were struck out. They relate to the extension of the area of supply of electricity, and to an agreement with the British Electric Traction Company.

**Government Telegraph Revenue.**—The last Post Office telegraph return gives the gross amount received by the Post Office in 1904 in respect of telegrams, private-wire rentals, special-wire rentals, and other sources at £4,208,426. From this sum the amount paid to cable companies, £529,520, and telegram moneys refunded, £4,748, must be deducted, leaving £3 674,137. The amount expended by the telegraph section of the Post Office in salaries, rent, and other respects during the same period is £4,693,897, the balance of expenditure over receipts thus being £957,782.

**Bradford.**—For some little time past the electrical engineer has been carrying out tests with the mercury vapour lamp. At Tuesday's meeting Alderman G. H. Robinson (chairman of the Electricity Committee) moved, and Mr. H. Hibbert seconded, a motion for the adoption of the minutes which contained a recommendation that the Council should select from a list submitted an expert to advise the committee as to the best way of carrying out the work of the department. After discussion, an amendment that the services of an expert be dispensed with altogether was carried.

**Marconi Installations.**—It is reported that an agreement has been signed between the two Government departments concerned and the Marconi Wireless Telegraphy Company for the installation of instruments for transmission of messages to the mainland from six lightships in the neighbourhood of the Goodwin Sands. The lightships to be supplied are "East Goodwin," "South Goodwin," "Gull" "Tongue," "Sunk," and "Cross Sand." The messages will be received at the Dover receiving station and forwarded by ordinary telegraph to the nearest lifeboat station in case of need.

**French Cable Co.**—The French Cable Company, whose local lines the President of Venezuela contemplates seizing, is an undertaking subsidised by the French Government. The *Birmingham Post* says this suggests serious complications. Following the high-handed action of the Venezuelan Government towards the American Asphalte Company there seems to be trouble ahead for the South American Republic, which has already sustained an Anglo-German blockade of its coasts. The French Cable Company, which has an office in London, is registered in France as the Compagnie Française des Cables Télégraphiques. It came into existence just over 10 years ago in succession to the French Atlantic Cable Company, and the system has been extended. By a subvention dated July, 1895, the French Government has given a subsidy of 800,000fr.; in addition the French and Australian Governments guarantee in respect of the Australian-New Caledonian cable annual receipts of 300,000fr. for 30 years from the opening of the line, together with a contribution to working expenses.

**Stock Exchange.**—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Charing Cross, Euston, and Hampstead Railway Company's scrip (fully and partly paid) for £800,000 4 per cent. perpetual debenture stock, and Great Northern, Piccadilly, and Brompton Railway Company's scrip (fully and partly paid) for £1,200,000 4 per cent. perpetual debenture stock, and to allow the following securities to be quoted in the official list: Charing Cross, West-end, and City Electricity Supply Company's further issue of £50,000 4 per cent. debenture stock; Liston Electric Tramways, Limited, £500,000 ordinary shares of £1 each fully paid, Nos. 1 to 500,000, 500,000 6 per cent. cumulative preference shares of £1 each fully paid, Nos. 1 to 500 000, and £500,000 5 per cent. mortgage debentures of £100 each, Nos 1 to 5,000 (registered); Metropolitan District Railway Company's £537,351 assented extension preference (5 per cent.) stock, and £962,649 unassented extension preference (5 per cent.) stock, in lieu or the £1,500,000 extension preference (5 per cent.) stock now quoted; Potteries Electric Traction Company's further issue of £25,000 4½ per cent. debenture stock.

**Leeds.**—A scheme is about to be carried out for supplying the suburbs of West Leeds with electricity at practically the same cost as that paid in the centre of the city. It is proposed to utilise part of the land recently purchased in Stanningley-road, near Bramley Town End, for a tramway depôt, whilst the remainder is to be reserved as a sub-station for electric lighting purposes. Current generated at Crown Point will be transmitted to the new station at Bramley, and from there for private usage in the Bramley, Stanningley, Rodley, and Armley districts. Messrs. Matthews and Yates have recently equipped five boilers at the Crown Point electricity station with their Cyclone induced-draught system. This firm, which has its works at Swinton, early this month supplied one of their No. 11 Cyclone exhausters and a 26-h.p. motor, which is wound for 550 volts, and runs at over 400 revolutions per minute. On the 9th inst. a test was made with the apparatus, with the result that more water was evaporated and with less fuel than by the old method of using steam-jets under the fires, which the fan draught has superseded. As a less quantity of fuel was used for evaporating a larger quantity of water than by the old method, it will, of course, be understood that smoke was not seen during the test period. As the combustion of the fuel was more perfect smoke could not be formed. Under normal working conditions, previous to the fan being fixed great annoyance had been caused by the black smoke emitted from the chimney. The class of fuel used was ordinary slack, and the water evaporated was equal to about 9lb. of water per 1lb. of fuel. Messrs. Matthews and Yates, Limited, have quite recently erected two other installations in Leeds, which are working satisfactorily, and they are also erecting a number of installations in the city of Bradford.

Digitized by Google

**Harrogate.**—At the last Council meeting it was proposed that the charges for lighting purposes be reduced as follows from July 1, 1905: flat rate from 5½d. to 5d. per unit; demand indicator, 6½. and 2½d. to 6d. and 2d. Councillor Sheffield, referring to this minute, asked how much surplus profit there would be for the relief of the rates after the reduction became operative. An amendment was carried requesting the Lighting Committee to consider the discontinuance of the demand indicator system, and to allow discounts.

**Sao Paulo Tramway Light and Power Co.**—This company was formed in 1899 to operate an electric railway, and also to carry on a lighting and power business in the city of Sao Paulo, Brazil. The capital is 7,000,000dol. in shares of 100dol. each, with 6,000,000dol. in 5 per cent. 30-year-old gold bonds of 500dol. each, redeemable in 1929. The common stock is in receipt of dividend at the rate of 8 per cent. The company owns and operates 60 miles of street track and 12 miles of steam railway. The shares are now quoted in London.

**Jarrow.**—Mr. Batey, the sanitary inspector, has made a detailed report to the Town Council in regard to the alleged smoke nuisance at the power station. He has made photographic observations and complained to the secretary of the power company. The company replied that they were fitting an apparatus on the boilers which they believed would remove any cause for complaint. While the fitting was proceeding further observations were taken on the centre chimney, to which the apparatus was fitted, and the inspector says that there is a slight improvement, but that it is not automatic.

**Burnley.**—It is proposed to reduce the charge for electric current to 3½d. per unit from 4d., and for motive power and heat from 3d. per unit for the first hour to 1¾d. for the first hour, and afterwards 1d. per unit. Public lighting will be reduced 50 per cent.—viz., from 3d. to 1½d.—and a further decrease is also announced in the charge for current for the tramways. This makes the fourth reduction since the trams began, which means a considerable help to the tramways department. The reductions have been from 2d. to 1⅞d., 1¾d., 1½d., and now it is proposed to charge 1·45d. The hire of motors is also to be lowered, the rentals being in ratio to capital cost. Further, arc lamps will be 15s. instead of £1.

**Aberdeen.**—The County Council have agreed to the granting of an electric lighting provisional order to Messrs. Lowdon Bros. and Co., Temple Electric Works, Dundee, for the Cults district, subject to the provisions contained in certain agreements entered into between the County Council of the county of Aberdeen, the Aberdeen District Committee, and Messrs. P. C. Middleton and Co., Limited, electric light and power engineers, and a further agreement entered into between the said County Council, the Aberdeen District Committee, and Messrs. Lowdon Bros. and Co., electrical engineers, Dundee, with the consent and concurrence of the liquidators of the said Messrs. P. C. Middleton and Co., Limited, in October, 1902.

**Dalkeith.**—The inauguration of the street-lighting by electricity took place on Saturday. Mr. K. Scott-Moncrieff, of the Electric Supply Corporation, Limited, London, who presided, presented to Provost Chisholm a silver electric switch, mounted on a marble slab, and which bore the following inscription: "Presented to John C. Chisholm, Esq., Provost of Dalkeith, by the Electric Supply Corporation, Limited, on first lighting up the streets of Dalkeith by electricity, 11th March, 1905." Provost Chisholm then switched on the current, a temporary wire having been laid into the meeting place from the street cables. The installation consists of 27 10-ampere arc lamps in three circuits of nine, and each of the lights is of 1,000 c.p.

**Luton.**—The electrical engineer's last report stated that since Jan. 27 45 698 units had been generated, and an equivalent of 72 8-c.p. lamps and four motors of 50 h.p. connected, making a total of 233 consumers with 14,182 lamps and 75 motors of 308 h.p. and that the units generated showed an increase of 79 per cent. over the number generated during the corresponding period of last year, and that at the present time applications were in for over 540 additional lamps and 248 h.p. in motors. The report was received. The electrical engineer has also presented a report as to the absolute necessity for an increase of plant to supply the present demand for power and light, and application is to be made for sanction to a loan of £5,000 for additional plant.

**St. Marylebone.**—The following estimate of expenditure has been prepared for the supply of distributor cables, house cables, and connections, as follows: nine miles of ·15 triple-concentric lead-covered distributor cable at £495 per mile, £4,455; seven miles of ·25 triple-concentric lead-covered distributor cable at £670 per mile, £4,690; house cables and connections, 500 at £2. 10s. per connection, £1,250—total, £10,395. The number of 500 connections is estimated by the resident engineer as the maximum number of new consumers likely to be connected during the year ending March 31, 1906. This expenditure is included in the original estimates of the consulting engineer, and is covered by the borrowing powers already sanctioned by the London County Council.

**New Company.**—The business of Messrs. Harris, Lee, and Co., 165, Queen Victoria-street, London, E.C., has been converted into a limited company, under the style of "Harris, Lee, and Co., Limited," and registered under the Companies Acts of the Transvaal. The management will be as heretofore, the partners having become directors of the new company, and holding the bulk of the interest. The company holds, among others, the sole agencies for South Africa for Messrs. Crompton and Co., Limited; the St. Helens Cable Company, Limited; Perfecta Seamless Steel Tube Company, Limited; Electric and Ordnance Accessories Company, Limited; Evershed and Vignoles, Limited; C. J. Thursfield and Co.; Zurich Incandescence Lamp Company; Gilbert Arc Lamp Company; Bastian Meter Company, Limited.

**Maidenhead.**—The electrical engineer in his last report states that the plant has run well generally since the last meeting, and that new consumers are coming in well again. Twelve services have been laid during the month, five of which are connected. There have been six further applications received since the last meeting, and the equivalent number of 8 c.p. lamps applied now exceeds 15,000. The following is a comparative statement of electricity generated, sold, etc., as furnished for the Board of Trade returns, and gives the increase in output of 1904 over 1903: quantity generated, 1903, 134,968 (1904, 218,497); sold to public lamps, 34 276 (51 236); sold to private consumers—by meter and contract, 66,827 (120,116); total sold, 101,103 (171,322); quantity used on works, 25,615 (46,316); total quantity accounted for, 126,718 (217 638); quantity not accounted for, 7,650 (859); maximum supply demanded, 156 kw. (212 kw.).

**King's Lynn.**—The last report of the borough electrical engineer states that during the month applications had been received for 76 additional lamps of 8 c.p. (or equivalent), making a total of 20,503 lamps and 508 consumers. The total number of Nernst lamps now in use for street-lighting was 32, and they give about 66 c.p. as compared with 32 c.p. in the ordinary street lamps, and consume about 15 per cent. less current. He estimates that if all the incandescent lamps were converted to Nernst lamps the extra cost per annum would be as follows: for renewals £190, for extra attendance £30—total, £220. Against this extra cost there would be an annual saving to the department in current of about £158. The first cost of converting the lamps would be 10s. to 12s. per lamp, or for the whole about £250. It has been decided to charge only 1½d. per unit for heating and cooking purposes, provided the current is registered on a separate meter, for which 1s. per quarter will be paid.

**Southampton.**—The electrical engineer, having suggested a reduction of the present charges, has been directed to prepare his estimate on the basis of a reduction of charge for the trams from 2⅛ d. to 2d., and to private consumers from 4½d. to 4d. and 4d. to 3d. for cellar and back lighting. A deputation from the Commerce of the Port Committee has waited upon the directors of the Telephone Company and their general manager (Mr. W. E. L. Gaine). The deputation having conferred with the company upon the subject of the suggested reduction of their telephone charges to subscribers in the county borough of Southampton, were informed that the Postmaster-General was negotiating for the purchase of the whole undertaking of the company, and that under the circumstances they could not consider any alteration in the charges at Southampton, although it was admitted that at Portsmouth and at two or three other places the charges were half of those existing at Southampton.

**Leicester.**—There is a profit of £3,947 resulting from the electric lighting undertaking for the half-year ending Dec. 31 last after paying interest on capital and £3 221 on account of sinking fund. The profit for the half-year ended June 30 last, as reported to the Council on Sept. 27 last, was £2,570, making the total profit for the year £6,518. The committee have reported on the question of providing additional plant at the electric lighting station. The present generating capacity of the station is equal to 3,400 kw. distributed between six alternators, two being equal to 1,000 kw. each and four to 350 kw. each. In December last the load reached 2,400 kw., necessitating the use of the two large machines and one small one. It is estimated that an additional 200 kw. will be called for next lighting season, requiring the use of a further small engine, leaving only two of the smaller type as spares. This the committee consider altogether inadequate should an accident occur to one of the large machines, and they have, therefore, accepted tenders for additional plant, particulars of which appear in another column.

**Dufftown.**—The Town Council have adopted a scheme for lighting the burgh with electricity. It is proposed to catch the water in the tail race as it leaves the Fife Mills at Orachie and use it to drive a turbine wheel. The flow of water there is taken to give, with a 7½'t. fall, a clear 13 h.p. to 13½ h.p. for the dynamo. The water would be taken in wooden troughs below Orachie Bridge, and then on the waste piece of ground near the railway bridge, where a hut would be constructed for the turbine and a small house for covering the machinery. The whole work is not to cost more than £700. This would give an installation of 120 to 130 16-c.p. lights, and as the present requirements of the burgh are 40 lights, 50 to 60 lights could be supplied to private customers at £1 per light of 16 c.p. per year. The annual expenditure is estimated as follows: interest on loan of £700 at 3½ per cent., £24. 10s.; sinking fund at 3½ per cent., £24. 10s.; water right, upkeep, and attention, £20—or a total expenditure of £69. An income of £60 would be got from private lighting, leaving a balance of £9 to be raised from the rates. This would be a saving of £30 to £40 yearly, as the present system costs the town from £40 to £50 per annum. The Council think that a provisional order would not be required, as there would be no danger of a rival company coming into the field.

**Swindon.**—The last monthly report of the electrical engineer shows that the number of consumers connected was 306, as against 163 in February of last year. The number of street lamps converted to date was 169, as against 126 at this time last year. The Electricity and Tramways Committee have recommended a reduction in the charges for electricity from March 31 as follows: Flat rate—to be reduced from 5d. per unit to 4d. per unit; maximum demand system—capital charge to be reduced from £7. 10s. to £6 per kilowatt; power charges—to be reduced from 2½d. per unit to 2d. per unit, with discounts as at present, and subject to the Corporation reserving the right to charge the 4d. per unit for all current taken between 5 p.m. and 10 p.m. in the winter months; street-lighting—25 per cent. larger lamps to be fixed as the old lamps give out, and the charges to remain the same as at present, excepting for arc lamps, the charge for which to be reduced from £17. 10s. per annum to £16. 10s. per annum; meter rents—consumers to be allowed one meter for the equivalent of every 180 lamps connected for lighting or power, without charge, and for each additional meter the rents to be as at present; discounts—that the discounts be discontinued; current for the tramways—to be reduced from 2½d. per unit to 2d. per cent. The report has been referred back.

**London County Council.**—The Highway Committee reported on Tuesday that the Council on Oct. 13, 1903, sanctioned expenditure of £2,000 in connection with the making of surveys, the digging of trial holes, and the preparation of plans, specifications, estimates, etc., for the second portion of the Greenwich electricity generating station. Considerable progress had been made with this preliminary work, but alterations in the drawings of the buildings had had to be made in consequence of the Greenwich sub-station being erected independently of the main buildings, instead of as part of that work as was originally intended. This had necessitated some additional expenditure, and the sum of £2,000 above referred to was now practically expended. In view of the fact that the second portion of the Greenwich generating station would be required for the electrical working of the Council's (northern) tramways, and that its erection and equipment, if and when decided upon, would not occupy less than about 2½ years, they thought that the remainder of the preliminary work, as regards the preparation of drawings and the taking out of quantities, should be completed without delay. In this connection they pointed out that the Council had already determined to proceed, as soon as the necessary arrangements could be made, with the reconstruction of the first section of the Council's (northern) tramways. In the circumstances, therefore, they suggested that additional expenditure of £1,500 should be sanctioned for the purpose above indicated, and recommended accordingly. A conference will be held on March 20 between the City Corporation, the London County Council, and the metropolitan borough councils with reference to the promotion of the parliamentary Bills dealing with the supply of electricity in bulk in the County of London.

## PROVISIONAL PATENTS, 1905.

MARCH 6.

**4593. To use electric currents so as to electrolyse baths made of different acids for the purpose of destroying all vegetable matter in wool, rags, and other fibres.** Squire Rogers, The Observatory, Liversedge, Yorks.

**4595. Improvements in stopping and starting hydraulic pumps, electrically driven or otherwise.** Thomas Robson Charlton and George Herbert Traver, 11, Royal-arcade, Newcastle-on-Tyne.

**4625. Improvements in electric hoist controllers.** Joseph Gershom Childs, Hawthorn-road, Willesden Green, London.

**4643. An electrical grower.** Colin Graham, 1, Little Ealing-lane, South Ealing, London.

MARCH 7.

**4700. Improvements in electric light counterweight fittings.** James McFarlane and Harold Watson, 154, St. Vincent-street, Glasgow.

**4716. Telephone exchanges.** Frank Albert Lundquist, 65, Chancery-lane, London. (Complete specification.)

**4727. Improvements in and relating to ventilating fans.** Crompton and Co., Limited, and Claud Crompton, Arc Works, Chelmsford.

**4728. An improved instrument for displaying and recording the wave-form of alternating electric currents or voltages.** Crompton and Co., Limited, and Rudolf Goldschmidt, Arc Works, Chelmsford.

**4731. Improvements in electric pushes or switches for operating electric bells, telephones, signalling, and for other purposes.** Cecil Shartman Wansbrough, 33, Cannon-street, London.

**4740. Improvements in electric arc lamps.** Herbert Edward Angold, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**4741. Improvements relating to electrical apparatus for transmitting and receiving signals.** Arthur Trevor Dawson and George Thomas Buckham, 7, Southampton-buildings, Chancery-lane, London.

**4760. Improvements in dynamo-electric machines.** Friedrich Frohlich and Rudolf Farkac, 7, Southampton-buildings, Chancery-lane, London.

**4763. Improvements in electric circuit breakers.** William Harding Scott, 47, Lincoln's-inn-fields, London.

**4780. Improvements in and relating to appliances for testing electric batteries.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (Nicolay Jacobsen, Norway.)

**4783. Improvements in and relating to prepayment meters.** The British Thomson-Houston Company, Limited, 83 Cannon-street, London (The General Electric Company, United States.)

**4786. Arc lamp.** Thomas Alfred Hearson, 22, Southampton-buildings, Chancery-lane, London. (Phönix Elektrotechnische Ges. m. b. H, Germany.) (Complete specification.)

MARCH 8.

**4801. Improvement in obstruction removers or life-guards for electric tramcars and like vehicles.** Montague Brown Mountain, Godfrey Marsden Gibson, and Arthur Falkland Howard Head, 55, Market-street, Manchester.

**4816. An improved apparatus for detecting leaks in electric circuits.** William Alfred Buckland, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**4827. Improvements in trolley poles for electric tramway vehicles.** William James Bowden and James William Cronkshaw, 6, Bank street, Manchester.

**4832. Improvements in or relating to electrical fittings.** John Dugdill, 5, John Dalton-street, Manchester. (Complete specification.)

**4845. Improvements in and pertaining to alternating-current motors.** The Union Elektricitäts Gesellschaft, in liquidation, 27, Chancery-lane, London. (Date applied for under Patents Act, 1901, March 12, 1904, being date of application in Germany.) (Complete specification.)

**4848. Improvements in arc lamps.** Philip Middleton Justice, 55, Chancery-lane, London. (Phönix Elektrotechnische Ges. m. b. H., Germany.) (Complete specification.)

**4852. Improvements in or relating to signalling apparatus for use with electric railways or tramways.** Amos Edward Barber, 165, Queen Victoria-street, London.

**4858. Improvements in connection with the compensating poles of electrical machines.** Elektrizitäts Act.-Ges. vorm. W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, April 16, 1904, being date of application in Germany. (Complete specification.)

**4859. Improvements in the field-magnet arrangements of alternate-current electrical machines.** Elektrizitäts Act.-Ges. vorm. W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, April 30, 1904, being date of application in Germany.) (Complete specification.)

**4867. Improvements in or relating to electric vapour apparatus, and more particularly to lamps of the character known as electric vapour lamps, or mercury vapour arc lamps, or hermetically enclosed arc lamps, or the like.** Charles Orme Bastian and George Calvert, Birkbeck Bank-chambers, Chancery-lane, London.

**4878. Improvements in and relating to electric distribution systems and controlling apparatus therefor.** The British Thomson-Houston Company, Limited, and Edmund Basil Wedmore, 83, Cannon-street, London.

**4881. Improvements in and relating to electromagnetic brakes.** The British Thomson-Houston Company, Limited, and C. B. Larzelere, 83, Cannon-street, London.

**4883. Improvements in or relating to central-station telephone systems working with a common battery.** Isidore Bernard Birnbaum and Francis George Bell, 322, High Holborn, London.

MARCH 9.

**4957. Improvements in printing telegraph systems.** Sydney Elliott Page, 28, New Bridge-street, London. (Frederick Joseph Swift, United States.) (Complete specification.)

**4960. Improvements in electrical multiple influence or condenser machines.** Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Heinrich Wommelsdorf, Germany.) (Complete specification.)

**4967. Improvements in connection with the braking arrangement of electric motors.** William Harding Scott, 47, Lincoln's-inn-fields, London.

**4979. Improvements relating to resistance units for rheostats, electric heaters, and the like.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (The Wirt Electric Company, Incorporated, United States.) (Complete specification.)

**4982. Improvements connected with the control of electric circuits.** Michael Chapman and George Luther Stone, 18, Southampton-buildings, Chancery-lane, London.

**4984. An improved receiver for use in wireless telegraphy.** John Groome Balsillie, Clun House, Surrey-street, Strand, London.

MARCH 10.

**5010. Improvements in apparatus for controlling and operating the points of electric railways and tramways.** Edward Cross, "Dunedin," Oxford-street, Rotherham, Yorks.

**5013. Improvements in and relating to telpherage or overhead electric conveyor systems and the like.** Henry Schuster Cowx, 556, Chester-road, Old Trafford, Manchester.

**5042. Improvements in electrically-operated pianos.** Joseph Weber, 111, Hatton-garden, Holborn, London. (Complete specification.)

**5045. A low-voltage electric light for motor vehicles.** Orlebar David Bruce Payne, 1, Broad-street-buildings, Liverpool-street, London.

**5049. Improvements in insulators.** Arthur George Bloxam, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Joseph Goffin, Belgium.) (Complete specification.)

**5059. Improvements relating to the application and distribution of electric motive power, particularly for use in starting machinery and for similar purposes.** George William Mascord, 27, Chancery-lane, London.

Digitized by Google

**5061. Improvements in elastic supports for cells and storage batteries.** Henri Tudor, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**5070. Improvements in cut-outs or safety devices for electric systems or apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**5073. Improvements in or connected with means for automatically breaking an electric circuit in the event of a leakage to earth.** Nalder Bros. and Thompson, Limited, and Arthur Frederick Harris, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

MARCH 11.

**5143. Improvements in electrically-driven steering gear.** William Horatio Harfield and William Routledge, 4, South-street, Finsbury, London.

**5149. Improvements in or relating to telephone and like transmitters.** Hahnemann Adolphus Cutmore, 315, High Holborn, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published March 30.*

1904.

**5634. Switch point and "frog" for the overhead equipment of electrical traction.** Bonthrone.

**6030. Telephone systems.** Parker and Adam.

**6104. Electric contact breakers or tremblers.** John Crisp Fuller, George Fuller, and Frederick Joseph Gordon.

**8398. Electrically energised pendulum clocks.** Granger.

**8575. Electrical device for shifting type carriers as well as paper carriers for typewriters, type telegraphs, and the like.** Benicke and Westerbeck.

**9103. Electric igniting devices for miners' safety lamps and the like.** Day. (Fabrik Elektrisher Zünder G. m. b. H.)

**9377. Electric treadles or contact makers for railway signalling and the like.** Wood and McKenzie and Holland, Limited.

**9744. Watertight covers for electric tumbler switches.** General Contracts Company, Limited, and Flood.

**10055. Supports for electric cables, hydraulic mains, and other conductors of power, especially suitable for use in mines.** Callender's Cable and Construction Company, Limited, and Ward.

**10248. Vapour electric apparatus.** Carolan. (General Electric Company.)

**10249. Vapour electric apparatus.** Carolan. (General Electric Company.)

**10456. Electric switches.** British Thomson-Houston Company, Limited. (General Electric Company.)

**10551. Arrangement of electric motors in or on electrically-driven vehicles.** Krizik.

**11041. Automatic electric circuit breakers.** Eckstein and Mellis.

**11470. Poles or electrodes of electrolytic apparatus and the like.** Atkins.

**11831. Gas or vapour electric apparatus for rectifying alternating electric currents and other purposes.** Von Recklinghausen.

**20627. Method for the electrolytic manufacture of water-jackets, casings, and the like.** Bosquet. (Date applied for under International Convention, Feb. 10, 1904.)

**21455. Electric time alarms.** Bromhead. (American Bank Protection Company.)

**25637. Space telegraphy.** Stone. (Date applied for under International Convention, Nov. 24, 1903.)

**25640. Space telegraphy.** Stone. (Date applied for under International Convention, Nov. 25, 1903.)

**26922. Arc light electrodes.** Weedon. (Date applied for under International Convention, Dec. 10, 1903.)

**27209. System of electrical distribution for railways and method of operating same.** Hallberg.

**29363. Electrical measuring instruments.** Lake. (Arcioni.)

## COMPANIES' STOCK AND SHARE LIST.

## NOTES.

**Telephony in Canada.** — The special committee appointed to consider the nationalisation of the Canadian telephone system have elected as chairman Sir W. Mulock, the Postmaster-General, who is in favour of public ownership.

**Change of Title.**—It is probable that the title of the Mechanical Engineers' Association of the Witwatersrand will be altered to "The Transvaal Institute of Mechanical Engineers," the present designation being somewhat umbersome.

**Personal.**—The first recipient of the John Fritz gold medal to be awarded by the joint committee of the four national American engineering societies will be Lord Kelvin. This honour has to be bestowed on the man most representative of and eminent in scientific advance in the engineering field.

**McMillan Memorial Fund.**—We are requested to say that Mrs. W. G. McMillan desires to thank, in her own name and in the names of her children, the numerous friends who so kindly contributed to this fund. On account of their great number it is impossible for her to thank them individually, and she trusts, therefore, that they will accept this notice in acknowledgment of her gratitude for their generous kindness.

**Electro-Harmonic Society.** — The final smoking concert of the season is to be held to-night in the King's Hall of the Holborn Restaurant, Mr. James Swinburne taking the chair at eight o'clock. An admirable programme has been arranged to wind up the season. The vocalists will be Messrs. Charles Saunders and Alexander Tucker, and instrumental music will be provided by Messrs. Izard and Gatehouse and the orchestra. Recitations and sketches, humorous and musical, will be contributed by Messrs. W. G. Churcher, F. Chester, and B. Gammon. We note that Hon. Secretary W. E. Lane has changed his address to Finsbury-pavement House, E.C.

**Effect of Radium on Rubber.**—The *Journal* of the Chemical Society contains an abstract of an article by Mr. R. Ditmar on the action of radium rays on caoutchouc. The power of radium rays of penetrating caoutchouc has been examined by Madame Curie's radiographic method. A "concentrated" preparation of de Haen's radium barium bromide was used, but the action of this substance was not sufficiently powerful to induce radioactivity in the caoutchouc itself. The following conclusions have been derived from the results of the experiments of the author and the investigations of Madame Curie. The radium rays ($\gamma$-rays) penetrate both crude and vulcanised rubber, but the former more readily than the latter, probably owing to its porosity. Caoutchouc itself may be rendered radio-active (Madame Curie). The loss of activity of caoutchouc in air does not take place in accordance with the law which usually obtains for solids.

**Maintenance of Tramway Tracks.**—It seems likely that before long municipalities and companies owning electric trams will make a move in regard to the law concerning the maintenance of tramway tracks. Under the Tramways Act of 1870 the maintenance of the track devolves upon the tramway undertakers, which was equitable when animal haulage was the vogue; but with mechanical traction the wear from the trams is restricted to the rails. On the other hand, motor 'buses and heavy traffic in general cause great wear and tear to the track, which sometimes extends over three-fourths of the carriage-way. Thus electric trams are not merely subject to the competition of the motorcar, but have to provide a track for the latter to wear out, although they do not contribute a penny towards its upkeep. Our tramway legislation is of the antiquated order, and it is quite time that amendments were made to bring it into harmony with modern conditions.

**Manchester Section.**—Following close on the heels of their seniors, the students of this section held a dinner—which is to become an annual function—at the Grand Hotel, Manchester, on Saturday, Mr. C. D. Taite presiding. The chairman congratulated the hon. secretary, Mr. A. E. Jepson, on the 200 per cent. increase in the membership roll since last year. He referred to the advantages that electrical students now possess as compared with one-time students, not merely in educational facilities, but in physical comfort as represented by well heated and ventilated workshops. Mr. E. W. Cowan also spoke in reply to a toast, and, dealing with the financial position of the industry, described how his mouth watered when he heard textile manufacturers in the district discuss the likelihood of having to refuse orders for cotton goods requiring delivery before July. Mr. F. O. Mills hinted that an active rivalry with the London Students' Section might be of general benefit. The evening was enlivened by more or less extempore speeches and more or less good songs, and we understand that the youthful gathering was quiet and decorous—presumably for students.

**The Underground.**—In the small hours of Tuesday a trial trip was made on the Metropolitan Company's newly-electrified Inner Circle system. The little party of railway officials included Mr. Ellis, general manager, Mr. C. Jones, chief electrician, and Mr. A. Ingram, superintendent of carriages and rolling stock. The generating plant, train equipment, and carriages have already been described in these columns. The run was made without a hitch, the only stoppages occurring at South Kensington and Aldgate, to change on to the other line. Smoothness of running and good acceleration were attained. This satisfactory result encourages the hope that the electric trains will be able to perform the complete journey round the Inner Circle, which now occupies 70 minutes, in 50 minutes. The Metropolitan Company have now completed the electrification of their system from end to end. The District Railway are also understood to be ready, but have not yet run their trial trips. As soon as these have been satisfactorily accomplished the arrangements for joint working will come into operation, and thenceforward passengers will be conveyed round the Inner Circle by electricity alone. In fact, the Metropolitan are considering the running of some of the new electric trains on their section from South Kensington to Aldgate next week. Londoners are therefore likely to enjoy shortly the luxury of travelling on the Underground without the familiar smoke and fumes.

**Entering Moving Trains.**—The folly of entering a moving train has often been tragically exemplified on the steam lines, and the practice is certainly to be strongly deprecated in regard to the "tubes," especially remembering the limited space between the platform gate and the wall of the tunnel. On the Central London Railway the other day, a newly-arrived Russian made a rush for a moving train just as the gate was being closed. He reached the gate almost at the same moment as that section of the train entered the tunnel, with the result that he was jammed against the wall of the latter, and it appears that only the promptitude of the guard in applying the emergency brake saved the passenger's life. He was removed to the hospital, suffering from a wound on the back of his head and grazes on his legs. In consideration of the passenger's misfortune and ignorance of the English language,

Digitized by Google

the company did not intend to prosecute, but owing to his and his friend's persistence in asserting that the accident was due to the company's carelessness, they felt compelled to do so. At Marlborough-street Police Court on Tuesday, the defendant told Mr. Denman, the magistrate, that he was pushed off the train, but after hearing the evidence, his Worship had no hesitation in rejecting the statement of the defendant, upon whom a fine of 40s. was inflicted. Incidentally Mr. Denman testified, from his own experience, to the great caution exercised by the company's servants. Happily these occurrences have been rare on the "tubes," due to the gate system operated by the guard on each platform.

**Technical Journalism.**—At a recent meeting of the American Trade Press Association, Mr. Arthur Warren, manager of publicity for the Allis-Chambers Company, delivered an interesting address entitled "A Plain Talk on Trade Journals." Mr. Warren, who has been a fertile contributor to the Press himself, discussed the various phases of technical and trade journals with great frankness. Dealing with advertising, he distinguished between exploiting a patent soap or medicine and pushing the sales of machinery. In the former case the advertiser appealed to an unsophisticated audience as represented by the world in general, but in the readers of the technical Press the industrial advertiser addresses a trained and experienced audience. Mr. Warren remarked that all manufacturers should realise the need of a publicity department, which was just as essential as a drafting-room or a factory. In a semi-humorous vein he deprecated the superabundance of the "Special" number, which is more in evidence on the other side of the Atlantic than here. Mr. Warren complimented the technical Press upon the high character and ability of its editors, and concluded with some suggestions for developing the news features of the journals. He recommended that members of the editorial staff should be allowed to circulate more freely through the shops and factories, making observations at first hand. Sometimes there were reasons for silence on the part of the manufacturer, as when he was developing a new invention, but, Mr. Warren observed, there should be a closer touch between the Press and the manufacturers.

**New Publications.**—The Harmsworth Encyclopædia promises to be a happy compromise between the very extensive works and the single-volume treatise. From the first three numbers which we have before us we notice that the work is printed in clear type, and is generously illustrated with maps, diagrams, and photos. A brief perusal suggests that the articles, of which there are to be 50,000, combine conciseness and completeness. The work appears to embrace the complete cycle of human knowledge, and great attention is given to science and technology. In this connection the following passage from the preface is worthy of mention: "An old encyclopædia is useless . . . . the discovery of radium and the investigation of its properties have profoundly modified our conception of the universe. The whole scientific world is eagerly awaiting developments, new and startling facts are bound to come to light before we publish the articles under letter R, and the latest views of science, up to the moment of going to press, will be found embodied in our pages." It will be noticed that the compilers speak confidently of the "new and startling facts" which are "bound to come to light" during the intervening months prior to the letter R being reached, but it is safe to say that if such events crystallise, the publishers will be as good as their word in including the latest information. We observe that the numbers before us include occurrences as recent as the assassination of the Grand Duke Sergius. Numerous experts are collaborating in the production of this work, which will comprise 40 fortnightly parts, published at the modest price of 7d.

**Milan Exhibition.**—We learn that the Association of Italian Manufacturers for the Prevention of Accidents in Factories will offer at the Milan Exhibition of next year several prizes for international competition, including the following: A gold medal and £330 for a new appliance for preventing accidents arising from contacts between primary and secondary windings in alternate-current transformers. No disturbance in the action of the transformer must arise in case of atmospheric discharges or abnormal increase of potential. A gold medal and £40 for a novel system of hand crane or winch fitted with a simple and practical contrivance to prevent the possibility of the handles revolving during the descent of the load. And a gold medal and £20 for a safety appliance, to be simple, strong, and reliable, to stop trucks automatically on an inclined plane on the hauling rope snapping. The appliance must be adaptable to existing plant. Applications to compete must be sent in not later than July 31, 1905, addressed to the Presidency of the Association of Italian Manufacturers for the Prevention of Accidents in Factories, Foro Bonaparte, 61, Milan. Appliances entered for the three prizes mentioned above must be exhibited at the competitor's expense, under such conditions as to allow of their being practically tested at the exhibition. No charge for space will be made to competitors who intend to exhibit their appliances, but applications must state the exact area needed. All inventions and appliances presented for competition remain the property of competitors, but the association will retain the drawings, models, and descriptions. Further information can be obtained from the director of the association, Foro Bonaparte, 61, Milan.

**Radioactivity.**—Prof. J. J. Thomson last Saturday delivered at the Royal Institution the second of his course of lectures upon "The Electrical Properties of Radioactive Substances." After discussing the three types of rays which have become familiar, he alluded to the more recently discovered class, which might be called $\delta$ rays. This newest kind was distinguished by want of penetrating power, for they could only get through a few millimetres of air at ordinary pressures, whereas the $\gamma$ rays, which were unaffected by the strongest magnetic and electric fields and were exactly analogous to the Röntgen rays, could pass through 6in. of solid lead. Reverting to the $\beta$ rays, Prof. Thomson gave an outline of the argument by which the volume of their particles was shown to be only one-thousandth of that of the hydrogen atom. These particles were sometimes designated negative electrons, to which the lecturer objected, on the ground that it at once suggested a positive electron, a thing of which not even the existence was known; he preferred the term "corpuscles." The mass of such corpuscles was invariable, wherein they differed from ions, which were charged atoms or molecules, and showed as many differences in mass as there were gases. It was while endeavouring to collect the electricity of the $\alpha$ rays, which were positively charged, and in mass were equal to nearly twice the hydrogen atom, that he discovered the new $\delta$ rays. He found that in an apparatus which should have indicated the presence of positive electricity, negative electricity was abundant, and he traced the cause of this down to the fact that the radioactive body employed in the experiment was pouring out an immense stream of particles which, like those of the $\beta$ rays, were negatively charged, but differed in that they were comparatively slow-moving.

**Board of Trade Reorganisation.** — The Commercial Committee of the House of Commons has submitted to the Premier a memorial on the subject of the Minister

Digitized by Google

of Commerce. This approves generally the report presented by the Departmental Committee last year, and expresses a hope that the measure will be introduced at an early date. The committee advocates that means shall be placed at the disposal of the Minister of Commerce of readily obtaining information and assistance from practical and experienced representatives of various branches of industry, and it considers that the Commercial Intelligence Committee of the Board of Trade, with some enlargement of its membership and functions, would be well adapted for this purpose. Other suggestions are that while the nominees of the Government departments for the Commercial Intelligence Committee shall be maintained as at present, the number of commercial members shall be increased from 6 to 12 or 15; that the functions of the committee shall be enlarged by enabling it to suggest measures for the development and improvement of our commercial relations at home and abroad, instead of being, as now, merely an advisory committee on questions submitted for its consideration; and that the committee shall hold regular meetings, to be presided over as far as practicable by the Minister of Commerce, who would thus be brought into direct communication with the commercial representatives of the committee and with the representatives of other Government offices. It is proposed that the committee's extended scope shall embrace powers to consider commercial treaties and tariffs, to organise commercial missions, to appoint commercial agents abroad, either resident or temporary, for the purpose of obtaining information, and to form channels of communication between the office of the Ministry of Commerce at home and those engaged in trade in any foreign country, colony, or dependency. In addition, suggestions are made for inter-departmental co-operation.

**Cantor Lectures.**—The second of the series of these lectures was delivered by Mr. H. L. Webb at the Society of Arts on Monday last. It dealt with the subject—the line. It was pointed out that in the early days of telephony the object to be attained was the transmission of articulate speech over a comparatively short distance, whether that distance was calculated in yards or miles; but far more was rapidly required, and within a few years talking over a thousand miles or so was not considered extraordinary. The line over which such speech was transmitted was the most costly part of the installation, hence from the commercial as well as the scientific point of view deserved the closest attention to be best adapted to the work it had to perform. The troubles to be countered were three—attenuation, distortion, and induction. Each of these was discussed in turn, and starting from the old telegraphic lines and views, it was shown how improvements had been effected. Iron gave place—except in some out-of-the-way places—to copper and bronze. Hughes suggested the twisted wire and the necessity to get a perfectly balanced metallic circuit. Then Heaviside (Oliver of that ilk), with his deep mathematical and physical insight, suggested that inductance should be used to counter the evils of capacity. At first the experiments to practically carry out theory failed, but, nothing daunted, America, in the persons of Mr. C. J. Reed and especially in Dr. M. I. Pupin, proved the correctness of the theory, and the capacity trouble became a thing of the past by the proper use of balancing inductance coils. The latter part of the lecture dealt briefly with the advance in raising the capacity of a 2·5in. duct from 50 pairs to 500 pairs, or even in special cases to 1,000 pairs of wires, with the difficulties of laying ducts, etc., in big towns, and the various methods of distribution adopted. Quite a number of lantern slides were shown, which made a very effective method of driving home to the minds of the audience these difficulties and methods for overcoming the same.

**Students' Dinner.**—The success of the first dinner organised by the Students' Section of the Institution of Electrical Engineers, which was held at the Holborn Restaurant on Thursday last week, augurs well for its annual repetition. Mr. H. D. Symons, chairman of the section, presided, and several leading lights of the profession were among those who attended as guests. The latter included Mr. Alexander Siemens (president I.E.E), Mr. W. H. Patchell (vice-president I.E.E), Prof. J. Perry, F.R.S, Prof. E. Wilson, and Mr. W. M. Mordey (vice-president I.E.E.) In these circumstances it is not surprising that a considerable amount of advice was tendered gratuitously. Nor judging from some remarks made by the chairman was it altogether unnecessary, for it appears the muster of students on this occasion was far larger than is usual at their ordinary meetings. The advantage to be derived from regular attendance of these meetings and the free interchange of opinions generally was, of course, pointed out, while the excellence of papers recently contributed for discussion was aptly referred to as proof of the ability of those who presumably aspire to great things in later life. The gist of the speeches may be summed up in a single sentence: "There is plenty of room at the top of the ladder." Competition is only felt by those who crowd round its foot and fail to ascend when given an equal chance. Prof. Perry would have his pupils aim above the target, as the Japanese are doing. It fell to Mr. Mordey to respond to the last toast, "The Guests." He remembered a conversation which took place during the pioneering days of the electrical industry, when, referring to the output of a certain machine, he expressed the value in amperes and volts. A then prominent engineer, to whom his remarks had been addressed, interrupted with the request that he (Mr. Mordey) should state in intelligible language how much copper wire the machine in question was capable of heating. If they considered the crude units and limited knowledge of those days, they would wonder, not that so little, but so much had been practically accomplished by such men as Henry Wilde, and others. Some good songs added considerably to the enjoyment of the after-dinner proceedings.

**Electric Railway Operation.**—At a recent meeting of the New York Electrical Society, Mr. Herbert H. Vreeland, president of the New York City Railway Company, delivered an address entitled "Electric Railway Operation in a Great City," in which he took occasion to deprecate the tendency of electrical engineers to indulge in costly experiments upon systems in actual operation, as though they were laboratory apparatus. The lecturer emphasised the necessity of the electrical engineer learning the practical conditions which must govern the successful application of his knowledge. The distance between the engineer and the claim agent or the auditor seemed remote until it appeared that the engineer's device, by its great intricacy or delicacy of construction in the hands of a not over-intelligent motorman, had involved the company in a disastrous accident, or, on the other hand, until the device had been tested, and its economic results written down in the auditor's cold figures, to elicit from the general manager the verdict that it is too costly. Mr. Vreeland remarked that the electrical engineer generally learned his business in some great establishment largely devoted to experiment, where the gross earnings of an ordinary street railroad were written off the books in a single month for fruitless investigation, and where he was provided almost superfluously

Digitized by Google

with the tools of his trade, with the result that when he came to handle street railway work it was sometimes difficult for him to realise that in the running of a car there is no time for repairs, and that no device, however generally useful, can be employed on a street car which, if it falls out of gear, requires the car to be stabled before it can be repaired. Another point to which he alluded was that no industry can afford to spend more than a certain fixed proportion of its earnings upon improvements. The expert, whether electrical engineer or other specialist, is rarely willing, the lecturer stated, to concede this condition of things, and was apt to become dismayed when he discovered that the funds available for improving appliances were strictly limited. In conclusion, the lecturer observed that if the electrical engineer expected to become successful commercially, he must adapt science to practical requirements instead of entering for constant innovations. We assume Mr. Vreeland's meaning to be that the engineer must contrive to strike the happy medium between a craze for novelty and the retention of the obselete.

**Royal Meteorological Society.**—An interesting exhibition of meteorological instruments arranged by this society was held last week in the library of the Institution of Civil Engineers. The development of recording instruments was well illustrated, as also the methods adopted for ascertaining the meteorological conditions in the upper air. The instruments used by Mr. J. Glaisher, F.R.S., in his famous balloon ascents for the British Association, 1862-66, Mr. W. H. Dines's kites and meteorograph used by him at Crinan, and Mr. W. S. Bruce's camera and meteorograph used with kites in the Scottish Antarctic expedition were to be seen. The thermometers, anemometers, and sunshine recorders used on board the "Discovery" in the recent national Antarctic expedition were also exhibited, as well as a number of beautiful water-colour drawings of sky and cloud effects in the Antarctic regions made by Dr. E A. Wilson. M. Richard, of Paris, showed a collection of most of his noted self-recording instruments, and Mr. Halliwell, of Southport, exhibited his new rain-gauges, anemometers, and evaporation tank. The Royal Meteorological Society arranged in a railed-off enclosure a typical climatological station. The Meteorological Council also showed in position the photographic barograph and the Beckley self-recording rain-gauge which were recently in use at the Fort William observatory. Many other instruments were shown, besides a large collection of photographs, records, drawings, maps, etc., illustrating meteorological phenomena. At a meeting of the society on the 15th inst., the president, Mr. Richard Bentley, delivered an address on "The Growth of Instrumental Meteorology." After briefly touching on the historic and non-instrumental era of meteorology, he spoke of the seven great weapons of meteorology—the thermometer, and of later years the heliograph, for temperature; the hygrometer and rain-gauge for moisture; the barometer for pressure; and the anemometer and kite for the study of the upper air; and of the great foundation of instrumental meteorology laid by Galileo, Torricelli, Wren, and Hooke. The president, in dwelling upon our indebtedness to Italy in science (as well as in art) from Galileo to Marconi, pointed out that the theory of rainfall was correctly enunciated as early as the beginning of the fourteenth century by Dante. He also dwelt on the great services rendered to the community by meteorologists, largely by volunteers at their own expense, and referred to the close observation kept by rain-gauges on the steadily diminishing water supply of the country, by anemometers protecting the traffic over some of our lofty and more exposed railway viaducts, by the use of the barometer for storm warnings and for the safety of miners in our pits, and by the heliograph with relation to the ripening of fruits and crops. The lecturer concluded by emphasising the importance of meteorology to the community in general, and appealed for greater assistance from the Government.

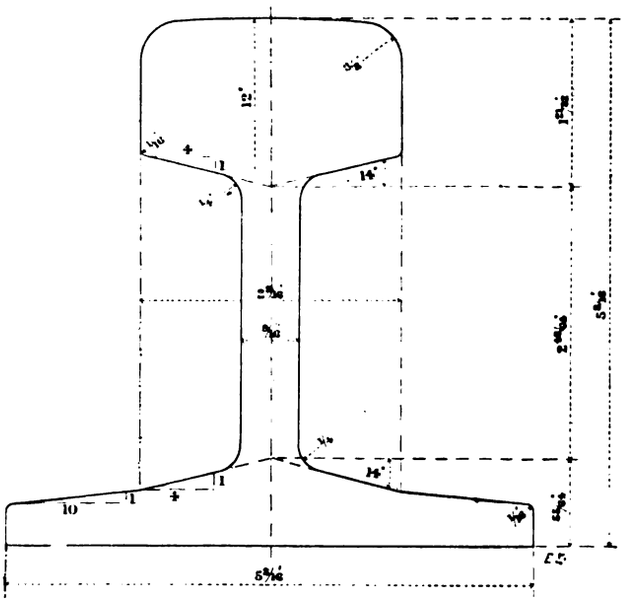
**Another Tesla Patent.**—We have received a copy of the judgment delivered in the United States Circuit Court in the case of the Westinghouse Company against the National Electrical Company, which had reference to the patents of May 1, 1888, for the Telsa polyphase system The plaintiffs contended that these patents were infringed by the defendants' synchronous motor and alternating-current polyphase generator. The defendants contended that Tesla's invention was the rotating field mode of operation, and that this was limited to a self-starting motor so operated; that their own synchronous motor with direct-current excitation was not covered by the Tesla patents, being simply a reversed two-phase alternating-current dynamo of a prior type used as a generator; and that the claims in the Tesla patents which introduced "direct-current excitation producing synchronous operation" must be limited to such use after the motor is started by the Tesla means and method and brought up to speed. The Court held that if the invention could be so limited the defendants escaped infringement; on the other hand, if it could not, the claims of the patents were broad enough to reach the defendant's method of operation. Reviewing the Tesla discovery, the Court defined it as a method to produce in the polyphase rotating field motor, the "whirling field of force,' and employment thereof was obtainable with or without direct-current excitation of the armature or secondary element. The fact that its use produced a self-starting motor without the aid of such excitation could not alone serve to limit the invention to that effect. The theory advanced of the obliteration of the alternating-current magnetisation by that of the direct current of the secondary element of the motor was not material, as the Tesla invention was unquestionably introduced in the operation of the defendants' motor, and the structure was within the patent description. The Court, therefore, held that "the defendants' synchronous motor structure and operation are within the generic invention covered by the claims of two of the fundamental Tesla patents; that the invention is utilised in the defendants' motor operation, notwithstanding the introduction of direct-current excitation to make it synchronous in lieu of the full realisation of the revolving field effect for self-starting; that such supplemental aid does not escape infringement with or without advantage in such association; and that in any view the combination patents referred to are not limited to after-effect of direct-current excitation, but apply to the defendants' combination." Judgment was therefore entered for the plaintiffs, the decree restraining the defendants from infringing the Tesla patents.

**Electricity Supply in London.**—The London County Council have just issued from their statistical department some analytical returns of the electric supply undertakings in London for the year 1903-4. The figures are rather late in publication, but the information given is of great interest to engineers. There were at the time of obtaining the returns 16 local authorities and 13 companies having powers under the Electric Lighting Acts, but of these the Council of Bethnal Green had not its scheme at work, and the St. Marylebone undertaking was still being supplied through the Metropolitan Electric Supply Company. Stoke Newington, another of the borough councils, obtained its supply in bulk from the Hackney Borough Council. The areas of the supply allotted to the com-

Digitized by Google

panies are described in the report, which clearly indicates the districts where there is competition. The table drawn up with this object shows that at Bermondsey, and also in Newington, a company is in competition with a local authority, and that in 11 other areas there are two companies in competition with each other. In comparing the returns made for companies and local authorities, it must be remembered that as a rule the local authorities make no charge for meters. The first table of prices shows the relative charges for private supply and for public lighting. Here at once there is evidence that when the local authority is the undertaker, the amount of street-lighting which is done electrically is much more than when the undertaker is a company. For instance, 25 per cent. of the total units sold by the local authorities and 18 per cent. of the net income are attributable to public lighting, while the average figures for the company are only 4 per cent. of the units sold and 2 per cent. of the net income. From other tables it is seen from the average returns that the local authorities supply at much nearer the cost of production than do the companies. This is, of course, what might be expected, as the companies are now, as a rule, paying good dividends, while the municipal undertakings have only to meet interest and sinking fund charges on their loans. These average ·8d. per unit, whereas the interest and dividends paid by the companies average 1·81d. It is interesting to note, however, that after these charges have been met the surplus available for the repayment of capital or for depreciation is ·78d. per unit for the local authorities and ·49d. for the companies. The return as to the allocation of charges when local authorities work dust destructors in conjunction with their generating station is interesting. The equivalent charge per unit generated for steam supplied from the refuse destructor is the factor which determines the advantage or otherwise of the combination. This charge is as low as ·2d. for Bermondsey and ·25d. for Woolwich. It increases to ·6d. for Hackney and ·5d. per Stepney, where an advantage may still be claimed. But at Shoreditch the charge now averages as high as 1·99d. per unit generated, whereas the total cost of the units produced from the steam station in the borough is only 1·819d. It would seem from this that the scale of charges between the two departments at Shoreditch needs to be revised. The following figures show how far ahead of the local authorities the London companies still are in respect of the amount of electricity supplied. In the year under review the companies sold 85,941,921 units, against 27,963,137 by the local authorities. The following additional particulars are also of interest: total capital raised by local authorities, £2,995,051; by companies, £11,815,101; revenue — local authorities, £400,668; companies, £1,498,717; expenditure — local authorities, £216,816; companies, £716,927; interest and dividends paid—local authorities, £93,019; companies, £646,834; average price obtained for private supply—local authorities, 3·59d. per unit; companies, 4·34d. The detailed figures of costs are exceedingly valuable for reference, but are too voluminous for individual comment.

**Engineering Standards Committee.**—We have received a copy of Report No. 11, which is devoted to flat-bottomed railway rails. It is provided that the rails shall be composed of from ·35 to ·5 per cent. of carbon, and from ·7 to 1 per cent. of manganese, while the proportions of silicon, phosphorus, and sulphur shall not exceed ·10, ·07, and ·07 respectively. The manufacturer shall furnish carbon and phosphorus determinations of each cast, and a complete chemical analysis, representing the average of the other elements contained in the steel, shall be given for each rolling. Such complete analysis shall be made from drillings taken from the rail or tensile test piece or pieces, and when the rolling exceeds 200 tons an additional complete analysis shall be made for each 200 tons. A margin of $\frac{1}{2}$ per cent. under to $\frac{1}{2}$ per cent. above the specified weight, and $\frac{3}{16}$in. above or below the stated length, is allowed. The general dimensions of standard rails range from Section No. 20, with height of rail 2$\frac{1}{2}$in., width of head 1$\frac{3}{8}$in., and the nominal weight in pounds per yard corresponding to the number of the section, to Section No. 100, with height of rail 5$\frac{3}{4}$in., width of head 2$\frac{3}{4}$in., and the nominal weight in pounds per yard corresponding to the number of the section. The accompanying diagram represents Section No. 85. The sections



of rail shall be accurately rolled to their respective templates, two sets of which, internal and external, shall, if required, be supplied to the purchaser. Rails are to be supplied for switches and crossings when so ordered, and such rails are to be of the required lengths, and cut from sound rails. For the impact test a piece of rail shall be selected from each cast. From this a piece 5ft. long, which may be taken from a crop end, shall be placed in a horizontal position, with the head uppermost, on two iron or steel supports resting on solid foundations, the upper surfaces of the supports being curved to a radius of 3in. The test shall comprise one blow, delivered midway between the bearings, from a falling weight or tup, the striking face of which shall be curved to a radius of not more than 5in. The weight of tup, span of test piece between centres of bearings, and height of drop for the various sections extend from 5cwt., 3ft. and 8ft. respectively for the 20lb. section to 20cwt., 3$\frac{1}{2}$ft. and 30ft. respectively for the 100lb. section. If any rail shows fracture under this test, the entire cast from which it was selected shall be rejected. The steel, placed in a testing machine of approved pattern, is to show an ultimate tensile strength equivalent to not less than 40 tons per square inch. Other matters dealt with include rails of special length for matching in curved line, branding, conditions of inspection, etc. A complete set of diagrams supplements the report, the price of which is 10s. 6d. Report No. 19 (price 5s.) deals with the temperature experiments on field coils of electrical machines carried out at the National Physical Laboratory. An abstract of the paper on this subject presented to the Institution of Electrical Engineers by Mr. E. H. Rayner, who conducted the experiments under Dr. Glazebrook's direction, appeared in our last week's issue.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

*(Continued from page 367.)*

### Two-Circuit Armatures with more than One Pair of Inductors per Commutator Section.

In all the examples of two-circuit windings so far discussed only two inductors per commutator section have been shown, but in many cases, especially for small machines, we may have many more.

This fact should, however, in no way lead to confusion, for the general laws of the winding are the same; only for each inductor we substitute a group, for each *pair* of inductors, a coil.

To show how this may be done, Fig. 20 has been modified from Fig. 14.

We assume that in place of 18 inductors there are 72, but still only nine commutator sections. In place of the simple connection 2 to 7 we get, as shown, a coil of four turns linking up *groups* 2 and 7, passing thence, on the one hand, *viâ* a commutator section to group 12, and, on the other, to group 15, exactly as in Fig. 14.

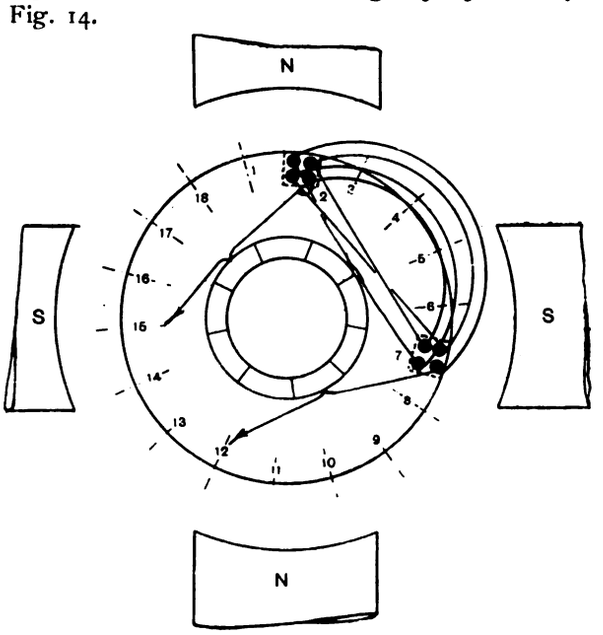

FIG. 20.

It follows, then, that in arranging any winding, the number of commutator sections is first determined and the winding arranged as if for a number of inductors equal to twice this number of sections: each of these inductors is then considered as split up to form a group until the total number given by the electromotive force formula is obtained.

It is obvious that the number of inductors must be both a multiple of the number of the commutator sections, and also, in the case of slotted armatures, a multiple of the number of slots.

### General Deductions.

1. Two-circuit simplex drum windings are those in which all the inductors are connected, so that they form between the brushes *two paths only* in parallel, no matter what be the number of poles.

2. This result is achieved by proceeding continually in one direction around the armature, with the end connections such that inductors lying in nearly similar positions under the various poles are connected immediately in series.

3. In order that the winding may close properly, it should obey the formula

$$w = p\,y \pm 2,$$

where $w$ is the total number of inductors on the armature;

$p$ the total number of poles; and

$y$ the mean number-pitch being a whole number.

If $y$ is an even number, the number-pitches must be taken alternately $y+1$ and $y-1$.

4. The total number of inductors must be a multiple of the number of commutator sections, and also, in the case of slotted armatures, of the number of slots.

5. However many poles the machine may have, two brushes only are essential; but, if desirable, there may be as many brushes as poles, without alteration of the winding.

6. On account of the shape of any section of such a development as Fig. 15, two-circuit windings are frequently called *wave windings* in contradistinction to those of the multiple-circuit type, which are called *lap windings*. This nomenclature, however, is again apt to be misleading, on account of the fact that some armatures may have more than one pair of inductors per section. Thus in Fig. 14 inductors 1 and 6 might form a complete coil of many turns whose end connections, however, would be arranged substantially according to the same system as explained on this page.

7. The same notation is used for these as for multiple-circuit armatures. Thus Fig. 19 will be described as a two-circuit four-pole drum, in which

$$w = 22$$
$$y_1 = 7$$
$$y_2 = 5.$$

The winding is simplex and re-entrant, and therefore denoted by the symbol o.

### Former-Winding of Two-Circuit Armatures.

Former-winding may be applied to drum armatures of this class, just as well as to multiple-circuit windings.

Thus in Fig. 20, if groups 2 and 7 lie in open slots, the coil shown would in all probability be wound apart from the armature, taped, and then slipped into position.

### The Same Armature as Multiple and as Two-Circuit.

It is clear that exactly the same coils might be used for a two-circuit as for a multiple-circuit armature, the end connections only being different.

Take, for instance, the armature of which Fig. 20 shows a portion.

There are nine coils, each of four turns, forming 18 groups of four inductors, each arranged in 18 slots with nine commutator sections.

If this armature is arranged as a two-circuit winding, the beginning of coil 2 to 7 is joined to group No. 15, and the end of this same coil to No. 12, and so on.

This armature will give, in a certain field, at a certain speed an electromotive force = V, and will carry without undue heating a current of C amperes.

If, on the other hand, we arrange it for a multiple-circuit winding, the coils will be the same, but the end of the coil just connected to group 12 will now be joined to the beginning of group 4, while that previously connected to group 15 will now be joined to the last inductor of group No. 5, and so on.

Under these conditions the armature will give $\frac{V}{2}$ volts, and at the same current density as before 2 C amperes, with the same field and at the same speed. This interchangeability is most useful to remember where many outputs are required from standard armatures;

Digitized by Google

and in getting out new patterns of armature discs we should always bear in mind that, while any even number of inductors may be used for a simple multiple-circuit winding, the same is not true for two-circuit armatures.

It is well, therefore, in designing the disc to keep in view the possibility of having to use it for a two-circuit winding. This, in the case of four-pole machines, often resolves itself into having a commutator with an odd number of sections, and a number of slots to suit.

Similar peculiarities immediately apparent in practice are proper to every number of poles, as shown by the formula. A multiple-circuit winding is, except so far as the actual pitch is concerned, independent of the number of poles; but a two-circuit winding is dependent upon the number of poles, not only for its pitch, but for the number of inductors possible.

*(To be continued.)*

## NEW LOCOMOTIVES ON THE VALTELLINA RAILWAY.

*(Concluded from page 263.)*

### Electrical Equipment.

Each group of motors is provided with a primary switch. The two switches are mounted on a common frame in the centre of the driver's cabin. They are of the piston type (Fig. 12), and are actuated throughout by means of compressed air. In the act of switching in, the plate carrying the contact rods is raised by compressed air admitted through the starting valve of the pneumatic or master controller. The break occurs at two contacts per phase. The motors can be reversed only when the primary switch is open, by turning the plate carrying the contact rods through an arc of 60deg. Two pistons are provided for this purpose, being connected with the reversing valve of the

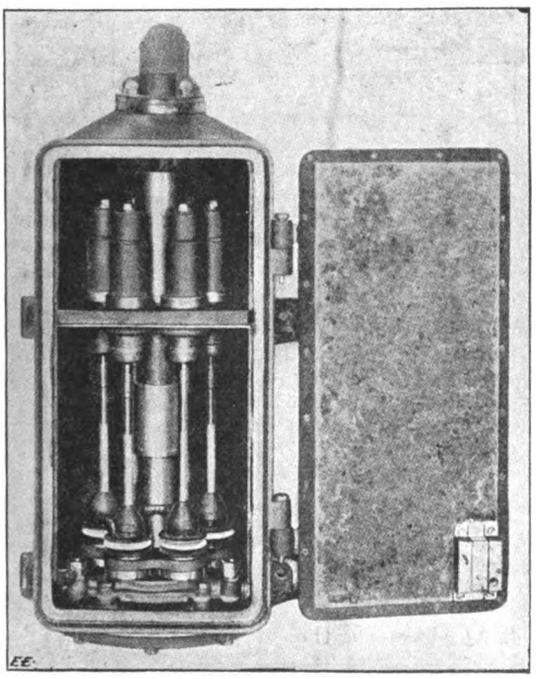

Fig. 12.—High-tension Switch.

master controller. According as the one or other piston is connected with the compressed-air reservoir or to atmosphere, the plate assumes one or other position.

The electrical controller serves to switch the two double motors in cascade or separate connection. Figs. 6-7 and 13 show the construction of this apparatus. It will be seen that the contact brushes through which the different connections are made, are carried by a shaft capable of movement in a vertical direction. Attached to the lower end of this shaft is a double-acting piston which works in an air-cylinder. The upper and smaller surface of this piston is open permanently to the compressed-air supply, so that the apparatus is usually held in the lower position, the motors being then in cascade. But when the corresponding lever of the pneumatic controller is set over to the full-speed position, compressed air is admitted through the

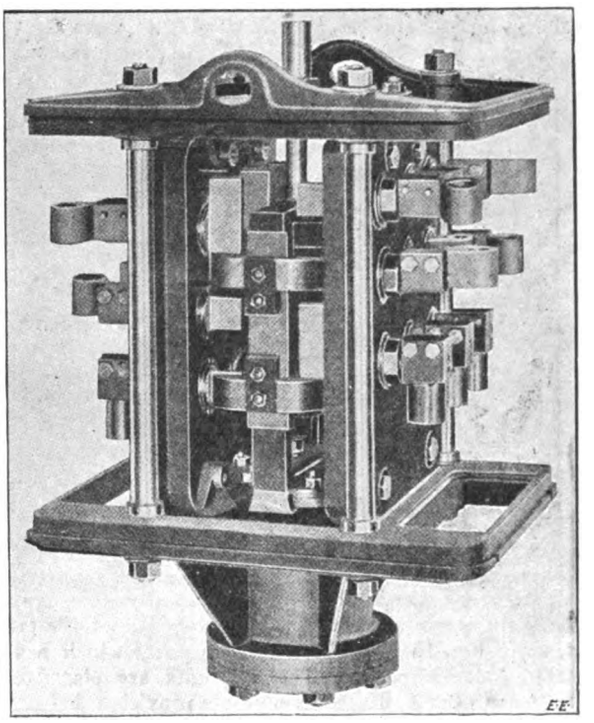

Fig. 13.—Electrical Controller.

speed regulating valve into the lower part of the cylinder, whereupon the shaft is forced upwards, due to the under surface of the piston being the larger. Thus the motors are put in separate connection. Since, however, the corresponding lever of the pneumatic controller can be moved only when the starting lever is in the off position, the motor controller cannot, of course, be operated except with the current off.

Each set of motors is further provided with a liquid starting rheostat. This consists essentially of a vessel having two compartments, the upper of which contains three groups of rheostat plates. These plates are clear

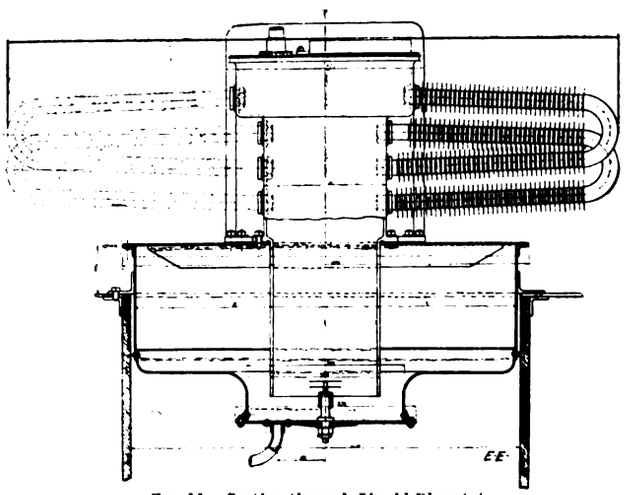

Fig. 14.—Section through Liquid Rheostat.

of the water when the motors are cut out. The resistance is inserted by admitting compressed air into the second chamber, so as to force the water up through the opening provided until it reaches the plates. The plate surface in contact with the water increases with the volume of air admitted until the resistance is reduced to its minimum, whereupon a short-circuiting device is operated automatically. Referring to Fig. 14, it will be seen that the chamber containing the rheostat plates is provided with an

Digitized by Google

extension which dips into the water-tank. It is through the lower end of this extension that the water is forced up by the compressed air. The system of valves by means of which the supply of compressed air to the rheostat can be regulated is contained in a separate compartment, as also the ball-cock which acts upon the valves. The former will be described in detail later on. The chamber in which the rheostat plates are suspended is situated between the above-mentioned compartments, and the plates themselves differ in length and shape. The plates belonging to the three phases are arranged alternately and insulated from

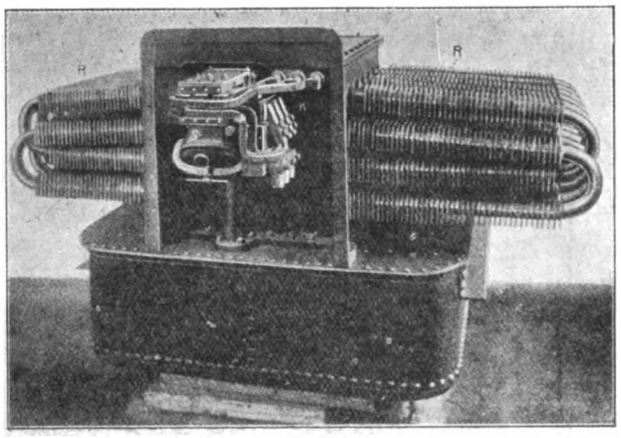

FIG 15.—View of Liquid Rheostat, showing Cooling Pipes and Short-Circuiting Device.

each other by means of porcelain insulators. A system of ribbed pipes which range out on either side of the tank, as shown in Fig. 15, serves to cool the water which has been heated in starting up. The rheostats are placed one at either end of the locomotive, ample provision being made for ventilating through the casing, as shown in Fig. 1, p. 155.

The arrangement of the regulating valves is shown in Fig. 16. The regulation is effected through the differential action of an electromagnet in the secondary circuit of the motors, as well as by the pressure due to the volume of compressed air admitted through the corresponding valve of the pneumatic controller. This pressure may, of course, be varied by admitting more or less compressed air, so that each position of the starting lever of the pneumatic controller corresponds to a certain starting current. The action of the system of valves may be explained with the aid of Fig. 16. The lever arm, M, attached to the shaft, *b*, is moved by the ball float in the water rheostat. If the level of the water in the plate chamber of the rheostat be low, the lever arm of the float will rest in the position indicated by the dotted lines and hold the valve T open, so that the water-tank of the rheostat is open to the space, W, below the smaller diaphragm. The valves P and N are closed by a spring; the two diaphragms are in their normal position; the armature of the electromagnet, *f*, does not exert any pressure through its support, *g*, since no current is flowing in the secondary circuit of the motor. When there is no air pressure in the chamber C, the valve H is opened by the spring $R_1$ and the piston D raised, so that the water-tank is connected with the atmosphere through the channel F, valve H, and channel E. The valves L, $N_1$, and R are held closed by the corresponding springs. The pipe A connects the system with the starting valve, while pipe B connects it with the regulating valve of the pneumatic

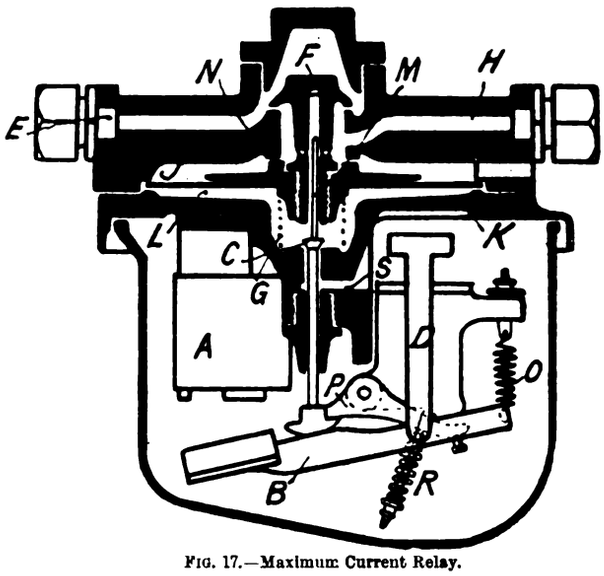

FIG. 17.—Maximum Current Relay.

controller. When the starting lever of the controller is put over to the first position, compressed air is admitted through the regulating valve into the pipe A and space C. The resultant pressure suffices to force down the piston D, and with it the valve H, thereby cutting off the water-tank from connection with the atmosphere. It is insufficient, however, to open the valve N against the counter-thrust of the spring S. Hence the rheostat is not yet switched in. By moving the starting lever further forward the regulating valve is also brought into action, thus admitting a certain volume of compressed air through the pipe B into the space, Q, between the two diaphragms. The upper diaphragm possessing the larger surface is consequently forced upwards, thus raising the valve N from its seat. Meanwhile, the valve P remains closed. The compressed air now passes through the valve N from the space C into the space W, and thence into the water-tank through the valve T, which has been opened by the lever connected with the float. Due to this action the water is raised into contact with the rheostat plates, and a current commences to flow in the secondary half of the motor, causing the armature of the electromagnet to be more and more attracted, until with the increasing current it exerts so

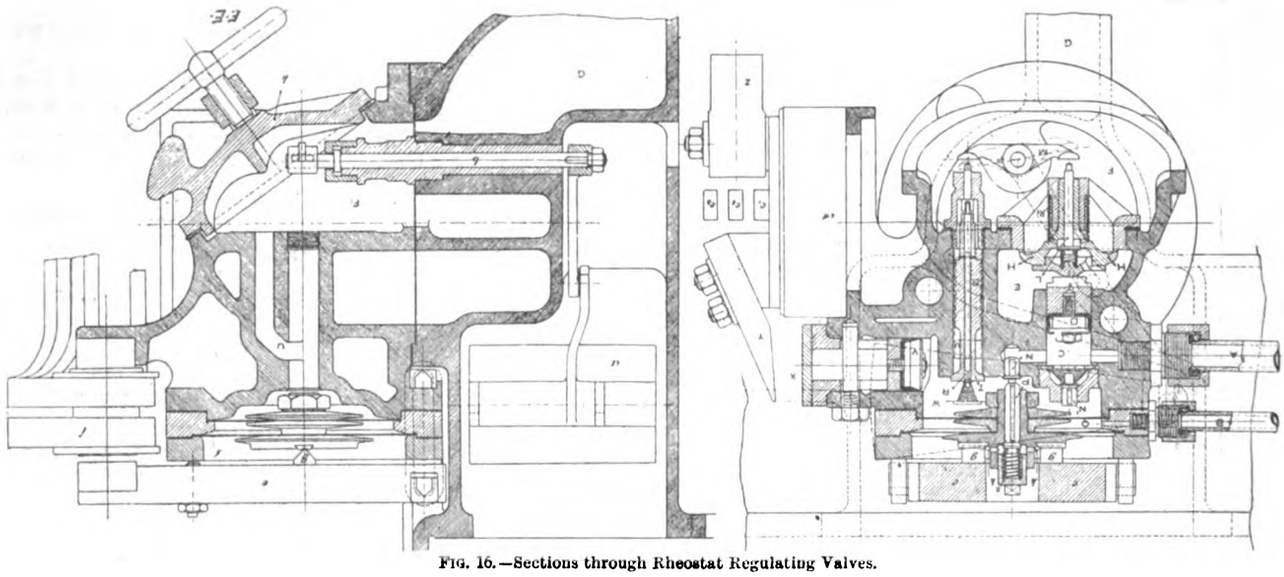

FIG. 16.—Sections through Rheostat Regulating Valves.

Digitized by Google

much pressure on the upper diaphragm that the latter is forced back. This, of course, tends also to close the valve N, and the volume of air admitted is lessened, until finally the diaphragm is forced so far back as to open the valve P, whereupon the compressed air escapes from the space W into the atmosphere. The current now decreases, since the water rises at a slower rate or maintains the same level, and consequently the pull of the electromagnet is weakened, the diaphragm again bulging outwards. Valve P is closed, valve N opened wider and wider, thereby again admitting compressed air to the rheostat. In this manner the water ultimately attains a level at which the arm, M, of the float falls back and the valve T is closed. The compressed air in the space W then expands, driving the piston V forward against the counter pressure of two powerful springs, and so short-circuits the three brushes, Y, through the contact piece, X, of the short-circuiter. When the starting lever of the pneumatic controller is reversed to cut the motor out, the state of the rheostat is not altered so long as compressed air is only released from the space, Q, between the differential diaphragms through the regulating valve and pipe B. Not until the starting valve connects the pipe and space C with the atmosphere does its action begin. The compressed air remaining in the space W then closes the valve N, and opens simultaneously the valve $N_1$, through which the air has an outlet. A relatively slight decrease of the air pressure acting on the piston V causes the latter to be forced back by the springs, and thus open the short-circuiting device. The piston D and valve H are simultaneously acted upon by their springs and the compressed air, being forced upwards. This establishes a connection between the water-tank and space E, consequently also with the atmosphere and chamber containing the rheostat plates, thus causing the water to sink rapidly. Should air escape due to leakage when the rheostat is switched in, the lever arm of the float raises the small valve, R, in valve T, causing the latter to be raised in turn, so that compressed air is admitted to compensate for the loss.

Referring back to Fig. 7, p. 262, it will be seen that an automatic relay is connected in the air-pipe from the starting lever of the pneumatic controller to the rheostat governor. The function of the device is to cut the motors out of circuit in case of overload. It is designed to release the compressed air from the rheostat, and so cause this to be cut out. Its action may be explained with the aid of Fig. 17. The device consists essentially of an electromagnet, A, excited by the earthed phase of the main circuit. Should the current reach its maximum, the lever, B, attracted by this electromagnet, opens a valve, C, and thereby establishes connection between the rheostat chamber and atmosphere. A time limit is imposed on the action of switching out by the oil dash-pot, D, which retards the movement of the lever B in proportion as the overload current is smaller or greater. Under normal conditions the pipe, E, from the pneumatic controller is open to the pipe, H, leading to the rheostat, through the valve F, which is raised by the spring, G. The space, J, above the diaphragm, K, is open to the atmosphere, whereas the space, L, below the diaphragm receives compressed air through the small inlet, M. Hence the diaphragm is forced upwards, and closes the valve N. The spring, O, opposes the pull of the electromagnet. As this pull increases with the square of the distance of the armature, and consequently the electromagnet would draw the lever up too quickly, the arm, P, is introduced, due to which the electromagnet can only come into play when its pull is sufficient to contract the spring, R. Then the valve C is opened by the arm, P, and the space below the diaphragm is connected to atmosphere through the opening, S. This causes the diaphragm to bulge downwards, opening the valve N, while the pipe, H, leading to the rheostat is connected through to the space J, and therefore to atmosphere. The compressed air in the pipe E also closes the valve F, so that no more air is admitted. When the rheostat is switched out of circuit, the lever and dash-pot arrangement returns to its original position, due to the action of the springs, as the current drops. However, the compressed air must be released from the pipe E before the rheostat can be inserted again, as otherwise the valve F remains closed—that is to say, when the relay has operated, the driver must put the starting lever over to the off position before he can start up again. The relay can be set to operate with any overload by adjusting a spring at the end of the lever P.

Referring once more to Fig. 7, it will be seen that an operating valve is provided in each of the pipes from the starting valve of the pneumatic controller to the primary switches. This valve serves a double purpose. In the first place, it ensures a quick make and break of the switch, and, secondly, delays the break so as to allow time for the rheostat to be switched out first. In switching in, a certain pressure is necessary to raise the valve against the opposing thrust of a spring, and this pressure must first of all accumulate in the pipe. When the valve is ultimately raised, the compressed air is admitted suddenly under the piston of the primary switch, and the make is instantaneous. In switching out, the air is released simultaneously from the pipes of the rheostat and primary switch, but while the rheostat is at once cut out, the pipe leading to the primary switch must exhaust to a certain degree before the valve can return against the reduced pressure and so re-establish direct connection between the piston cylinder and atmosphere. When the return does take place, the sudden reduction of pressure causes an instantaneous break.

On referring to the diagram of electrical connections (Fig. 6), it will be seen that provision is made for two small transformers. Of these, however, one only has been installed at present, as it is desired to find out whether one transformer and one air-compressor will suffice for actual requirements in practice. The 5-kw. transformer is of the oil-cooled type and transforms current from 3,000 to 110 volts, at which latter pressure the driving motor of the air-compressor is supplied. This motor is coupled direct to the compressor, which runs at a speed of 430 revolutions per minute. The compressed air is conveyed to the air reservoirs through a non-return valve and an oil separator. Two such reservoirs are provided, both carried on the roof of the locomotive. One of these supplies compressed air for the electrical apparatus, while the other serves the Westinghouse brakes. The compressor motor is controlled by means of an automatic switch, which is operated by the pressure in the reservoirs, being closed or opened according as the pressure is reduced or increased above six atmospheres. This switch is fitted with carbon contacts, and the interruption of each phase occurs at two points. When the pressure in the air reservoirs exceeds a certain limit, a diaphragm admits compressed air to a piston working in a cylinder. The counter-thrust of a coiled spring is thereby overcome, and the carbon contacts are raised. On the other hand, when the pressure in the reservoirs is reduced the diaphragm releases the air from under the piston, which the spring then drives back, and the carbon contacts close the circuit. A three-pole hand switch is provided for emergency use. There is also a small hand pump installed, which enables the air reservoirs to be filled independently of the electrical equipment.

Each end of the driver's cabin is provided with a voltmeter, an ammeter, and a manometer. The signal whistle is operated by compressed air, as likewise the sand sprinklers. Hand brakes and automatic Westinghouse brakes are fitted to the locomotives. These act only on the six driving wheels, there being two brake blocks to each wheel, one at either side. Two of the new locomotives are equipped as described in the foregoing, but the third differs in that metal resistances have been fitted experimentally instead of liquid rheostats. This departure has necessitated, of course, the use of a modified form of pneumatic controller and different apparatus for regulating the resistance. In other respects the equipment of the third locomotive resembles that of the other two.

The modified form of pneumatic controller is shown in Fig. 18. As in the case of the type previously described, levers are provided to operate the valves connected with the reversing gear and motor controller respectively. Moreover, the action of these valves is the same for both types. But whereas in the former a starting lever was also pro-

Digitized by Google

vided, this is substituted in the modified controller by a hand-wheel which operates a pneumatic starting valve, and at the same time regulates the resistance mechanically. This hand-wheel is mounted loosely on to the vertical shaft of the apparatus. It drives the outer cylinder, which is free to rotate within certain limits, through the medium of toothed gearing contained in the box, G, and it also drives the shaft. When the wheel is turned, the outer cylinder first revolves and operates in its turn

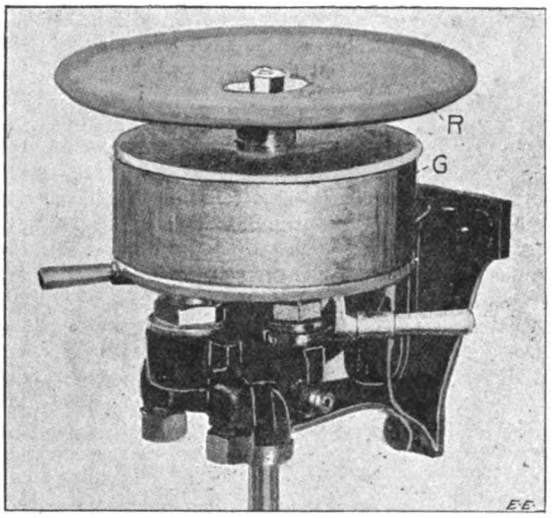

FIG. 18.—Pneumatic Controller on Locomotive fitted with Metal Rheostats, Valtellina Railway.

the starting valve, thus admitting compressed air to the primary switches. The outer cylinder is not capable of further movement in a forward direction, but now that the starting valve has been opened the shaft of the apparatus, which was previously stationary, is free to rotate, whereby the resistance switch is actuated through chain gearing and the individual units successively cut out until the whole resistance is short-circuited. The resistance regulators belonging to both sets of motors are moved

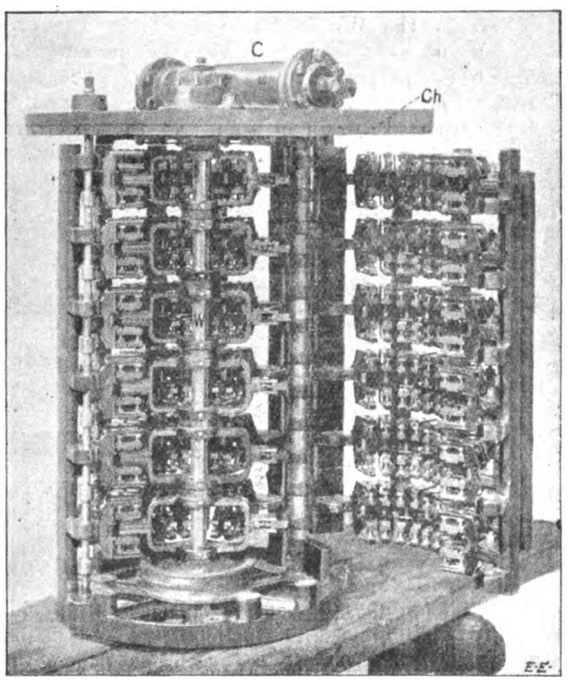

FIG. 19.—Regulator for Metal Rheostat.

simultaneously. For the rest the two controllers are interconnected in the same way as those of the type first described, while similar means are employed to minimise the possibility of mistakes by the driver.

The regulating apparatus (Fig. 19) for the starting rheostats consists of six rings of contacts insulated from each other, and connected to the secondary terminals of the motors on one side and with the individual sections of resistance on the other. The knives which engage with the contact jaws are carried by a vertical shaft actuated from the pneumatic controller through a chain and sprocket wheels. When this shaft is turned the resistance is cut out in sections until the last position is reached, at which the secondary terminals of the motors are short-circuited. There are two rheostats, one at either end of the locomotive. Each (Fig. 20) is built up of a number of units composed of German-silver strip. The regulation is effected in steps, and it is noteworthy that each position of the starting gear no longer corresponds to a constant current, as in the case of the locomotives previously described, but to a certain step, and the driver must keep an eye on the ammeter and regulate constantly, in order to keep the current within the desired limits.

An automatic relay similar to that in the other locomotives is provided to cut the resistances out in case of overload. For this purpose an air-cylinder, C (Fig. 19), in which a double-acting piston works, is mounted on the top cover of the regulating switch. The movement of the piston is transmitted through a worm shaft and toothed wheel to the vertical shaft of the switch. One end of the cylinder is connected with the starting valve of the pneumatic controller, and the other end with the automatic relay. Under normal conditions the pressure on the two sides of the piston is equal, and the shaft of the regulator can be moved freely. But when the relay operates it releases air from one side, and the excess pressure on the other side then

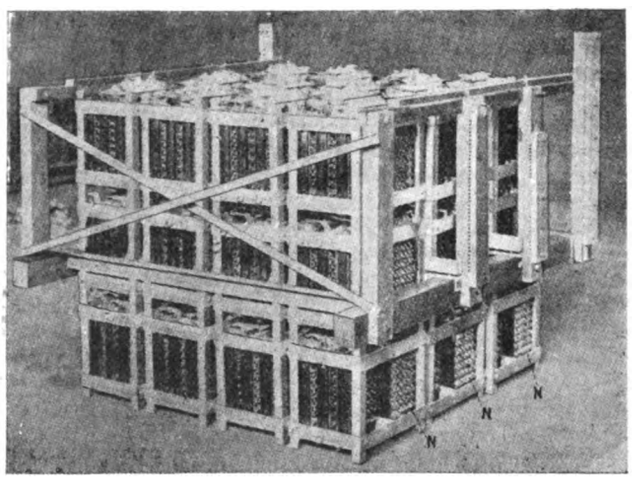

FIG. 20.—Metal Starting Rheostat.

causes the switch to be opened. At the same time the hand-wheel of the pneumatic controller is brought back to the off position, due to the connection through a chain and sprocket wheels. In order to prevent injury to the driver, the hand-wheel is of the smooth disc type.

It remains to add that the three locomotives were delivered in the spring of last year, and are used for hauling both passenger and goods trains. They have, so far, given complete satisfaction. It is noteworthy in this connection that the first of the trio continued in service for a month before it was withdrawn for a day's overhauling. All three locomotives are now in regular service, and haul passenger trains of 250 tons and freight trains of 400 tons total weight. They were thoroughly tested during their trial runs, and proved to meet all requirements.

[It will be admitted that these locomotives mark a great advance in railway work, and are a triumph of which Messrs. Ganz and Co. may be justly proud. We would remind our readers that Messrs. Bruce Peebles and Co., Limited, Edinburgh, are the firm's worthy representatives in this country, at all times prepared to undertake similar work.—ED. *E. E.*]

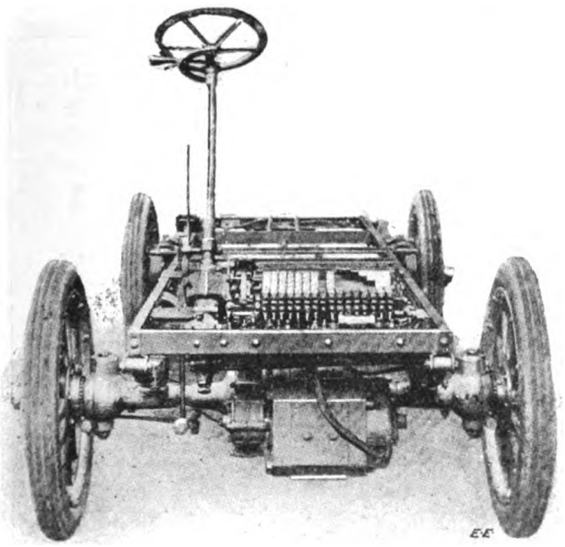
## THE MOTORCAR SHOWS.

Visitors to the automobile exhibitions held at Olympia and at the Agricultural Hall cannot fail to have been impressed not only by the growth in the size of the shows, but by the interest now taken in such exhibitions by the general public. Those interested in electrically-

Digitized by Google

propelled vehicles will also have realised that although those cars exhibited were fairly representative of the types now in use, they were comparatively few in number, and that among those to be seen structural improvements were more numerous than electrical, and in some instances were the only changes found to be desirable. The use of electric cars is still limited, and must necessarily be so as long as the distance they are able to run and the speed at which they can travel is restricted by the limited capabilities of even the improved accumulators now obtainable. The weight of these cars and their operating cost is not less than double that of cars propelled by other means, but there is a sufficient demand for these vehicles by people who are indifferent to such considerations, and who attach more importance to quietness of running and freedom from vibration, together with other advantages inseparable from electric cars, to encourage their construction and gradual improvement by the few firms engaged in their manufacture.

The Silvertown Company's chassis, exhibited by Messrs. W. and F. Thorn, is an example of excellent work and is well arranged. It is equipped with two series-wound totally enclosed motors, one driving the rear wheels through a live axle and single-reduction gearing, and the other the front wheels through similar gearing. Universal joints inside spherical steering heads are required to enable the power to be transmitted to the front



The Silvertown Chassis.

wheels, when they take up angular positions for steering. The weight of the cells and motors is well distributed, and it is claimed that by driving all four wheels the tendency to skid on slippery road surfaces is very much reduced. The controller is arranged across the front of the frame, and is in a protected and yet very accessible position. There are eight forward running positions, five for braking and five for reversing. Recuperation is not attempted, and it is reasonably claimed that for town running such provision is of little use, gradients usually being few and slight. When changing from series to parallel positions, the circuit is opened on a carbon circuit breaker, and flashing at the controller contacts is prevented. There is also a connection between the foot-brake pedal and the circuit breaker, so arranged that when slightly depressed for a momentary check of the car it may be opened and closed again without returning the controller to the neutral position. If, however, the pedal is sufficiently depressed to apply the brakes then the circuit is broken, and remains open until the controller is returned to the neutral position for restarting. The arrangement provides some protection against unskilled driving, and should be useful for traffic running. The complete car exhibited is provided with a very handsome brougham body seating four persons, with a canopy top extending over a roomy front seat for an additional passenger besides the driver. Various types of cells are employed, and a running distance of 35 miles on level roads with a single charge is guaranteed.

The cars exhibited by the Kriéger Electric Carriage Syndicate, Limited, have undergone little change, and they are similar to those which may be frequently seen in use in London, and which may be recognised by their distinctive method of driving the front wheels. The front or steering wheels are each independently driven by a two-pole shunt-wound motor supported on a swinging arm, the point of attachment of which is coincident with that of the pivoted wheel axle. The motors are suspended from laminated springs fixed at their inner ends, and an easy drive is obtained with diminution of shocks at starting and stopping and of the stresses set up in the gearing. A pinion on each motor spindle gears into an internally toothed ring on the road wheel, and with this single-reduction gear there can be little loss in transmission. The motors are entirely enclosed, but provision is made for easy examination of the commutators and brushes. The arrangement of the controller provides for electric braking and for recuperation when descending gradients at high or low speeds, or when the cells are connected in two groups in parallel or all in series. Mechanical brakes are also provided, acting on drums on the rear road wheels. Fulmen cells are employed; they are 44 in number, and their capacity is 204 ampere-hours. The weight of the car with landaulet body to seat four persons is about 30cwt., and a distance of from 40 to 50 miles may be run on one charge.

The Ekstromer Accumulator Company exhibited a two-seated car provided with a battery of 48 cells having a capacity of 240 ampere-hours. The weight of the cells in their containing crates is 14cwt., and the weight of the car complete is 30cwt. The motor and gear shafts are hung below the centre of the car, and the pinion on the motor shaft gears into a spur wheel on the differential gear and side chain pinion spindles. The second stage of the gear reduction is through the side chains to the sprockets on the rear road wheels. Strong claims are made as to the capabilities of the cells, and tests by independent authorities have shown the watt-hours of discharge per pound of cell to be about 14. The car exhibited has run a distance of about 3,000 miles, and the cells have been in use nine months. It has been run from London to Bath, a distance of 108 miles, on one charge, the volts at the commencement and finish of the run being 108 and 92 respectively. The average speed was 13½ miles per hour. Observations taken during a run from Portsmouth to London, on unfavourable road surfaces and over a more hilly course, showed the watt-hours per pound of cell to be 13·9. The average speed during this run was slightly over 10 miles per hour. Information as to the longevity of the cells is not yet available.

The Mors Company, who are agents for the Compagnie Française de Voitures Electromobiles, exhibit an electric brougham propelled by a single motor hung from the forward end of the frame, driving the rear road wheels through a propeller shaft and bevel gearing. The motor is constructed with two fields and two armatures, which arrangement permits of four speeds without altering battery connections, the cells being always in series. The controller provides for the four forward running speeds, one reverse, and electric braking. Other electric vehicles were exhibited possessing features of interest, among which were those of the Electromobile Company, which we hope to refer to in another issue.

Considerable interest attaches to the exhibits of those firms engaged in the manufacture of the variety of auxiliary parts required for the different electrical ignition systems for petrol motorcar engines. The use of these parts in very large numbers has stimulated invention, and has resulted in considerable improvement in design and construction for particular requirements.

We are unable to now refer to more than a few of the numerous exhibitors of these very necessary accessories, but among those who are well known to manufacturers and owners of automobiles are Messrs. Peto and Radford, Van Raden and Co., United Motor Industries, Limited, J. Lacoste and Co., John C. Fuller and Son, etc. A great variety of accumulators, dry cells, and primary batteries for ignition purposes are shown, and among these attention may be directed to Messrs. Van Raden's woven glass accumulators. These have been manufactured for some years, and have acquired a high reputation for use with motorcars. They

Digitized by Google

differ from other types of accumulators in that the carrier of the active material is not made entirely of lead, but is formed of a grid in which lead wires are interwoven as a warp thread, with extremely fine elastic glass wool as a weft. The material is pressed into these woven grids, and is very securely held. The plates, before being assembled, are enveloped in a sheet of spun glass. By this means good insulation is obtained, and the plates receive support over their whole area. The spun glass is extremely porous, and the plates may be arranged close together without liability of short-circuiting and the internal resistance of the cell is reduced.

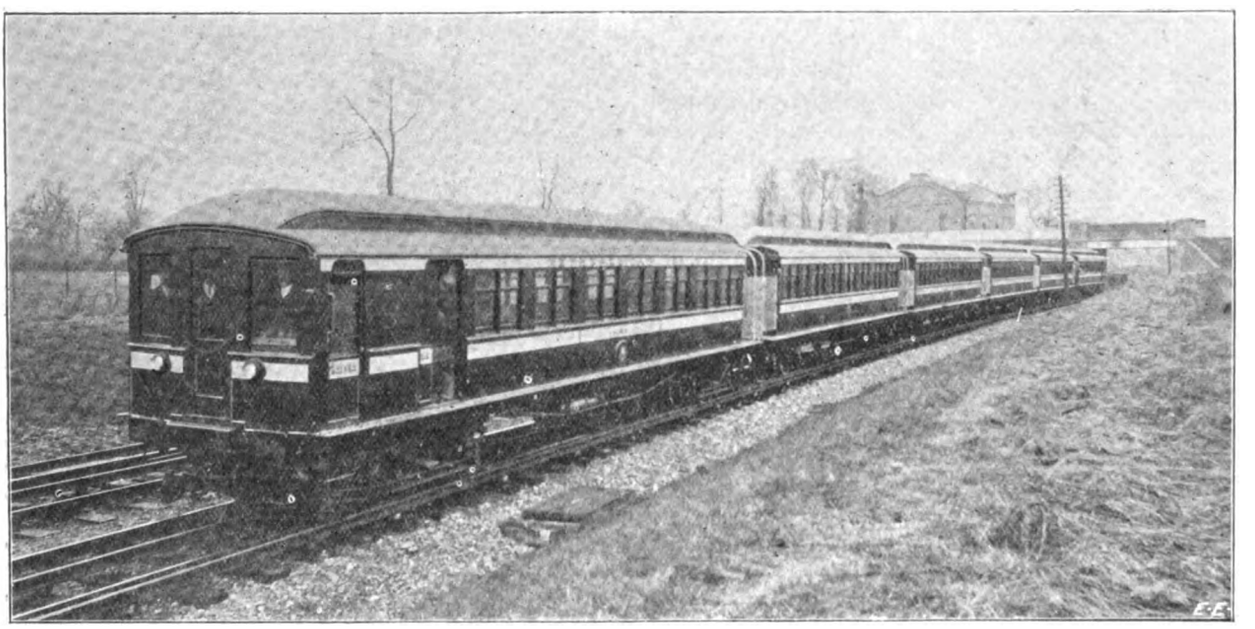
Induction coils of various sizes and of rectangular external form are shown, fitted with the well-known Carpentier trembler. Single coils, or groups of two, three, and four coils in single cases, are arranged for engines having from one to eight cylinders, and they are uniformly well finished. The Hospitalier-Carpentier manograph or indicator for high-speed engines, which is now receiving considerable attention, is exhibited.

There are a few exhibits of primary cells for ignition purposes, and the "Primol" Syndicate have produced a bichromate battery of simple construction which appears to possess advantages. The cells are arranged in boxes three in series, and the electrodes are carbon and zinc. The cells are hermetically sealed, and a neutralising agent is added to the electrolyte to prevent the evolution of gas. When the cells are not in use they must be inverted in order that the zincs shall not be immersed, but attention has been paid to easy withdrawal of the cell-box without disconnecting wires, sliding contacts being used. The cells are of small dimensions, are much lighter than accumulators, and renewal of the electrolyte after 1,000 miles running is easily done. The zincs may be used for the equivalent of a running distance of 6,000 miles, and are then simply replaced at very small cost. The weight of the three cells in their containing case for car purposes is 5lb., and for motor cycles 3lb.

Magneto-electric ignition is becoming much more commonly employed, and the arrangement of magnetos to work with induction coils, or with the induction coil or its equivalent included in the magneto, enables sparking plugs to be used at the motor cylinders instead of the more complicated mechanical contact gear hitherto required with the low-tension current from the magneto used without the induction coil. Space will not permit a description of these machines, but it may be stated that while they fulfil the electrical requirements satisfactorily, some of them are either of too delicate contruction to be durable, or have parts which require some attention, and which are not likely to receive it, since they are, in some instances, cased in and out of sight. The magnetos used on the Albion and on the Lanchester cars respectively of the high and low tension types are of simple and substantial design, and have proved themselves satisfactory. The Simms-Bosch and Eisemann magnetos are of more compact design, and are more commonly used at present.

The Kennedy Motor Company show their Simplex ignition plug, in which a magnetically-operated contact breaker is employed to cause a rapid make and break or trembler action at contact points in the combustion chamber of the engine cylinder. It is used with an accumulator and a contact breaker of the usual form in circuit, and subject to freedom of action when hot, and when some attention is given to lubrication should prove a satisfactory method of ignition. With multi-cylinder engines its application would be more costly than the usual high-tension coil and accumulator system of ignition.

An interesting application of Messrs. Crompton's electric pyrometers may have been observed by some of those who inspected the Clarkson steam omnibuses at the Olympia show. It is there applied to indicate the temperature of the steam as it leaves the generator on its way to the engine, and to enable the driver to keep the degree of superheat of the steam within predetermined limits. Such an instrument is of value to steam-car constructors, and Messrs. Crompton have supplied us with particulars of its construction and application to steam cars and of its use for various other purposes. They have paid particular attention to strength of construction and to so designing the indicating instrument that it shall be capable of withstanding the vibration it is subjected to on motor vehicles. The indicating instrument may be fixed in a suitable position for easy observation by the driver, and it has a clearly-divided scale 5¼in. long. For other applications a larger scale is used, and in the types more commonly used it is suitable for temperature ranges of 200deg. to 800deg. or 1,000deg. F., or for higher temperature ranges of from 400deg. to 1,100deg. C. We hope to more fully describe these instruments later, but it is interesting to record their application for steam-car purposes.



## THE METROPOLITAN RAILWAY COMPANY'S ELECTRIC TRAINS.

Above we reproduce a photograph of one of the electric trains delivered by the British Westinghouse Company to the Metropolitan Railway. The full details of the electric equipment appear in our description of the electrification of this line. The photograph shows more clearly than our previous illustration the general appearance of the electric trains which are now running regularly on the Baker-street to Uxbridge section of this line. We need only add that the comforts of the new rolling-stock propelled by electricity are much appreciated by the public living in the Uxbridge district.

## TRAMWAYS PERMANENT-WAY CONSTRUCTION AND MAINTENANCE.*

BY JAMES LORD, A.M.I.C.E.

This subject is one which has been considerably debated in all its bearings during the last 15 years, and it may seem at first sight that nothing new can be advanced; such I venture to suggest is not the case, and the matter is still full of interest after 15 years' experience. I propose this evening not to take up time by enumerating and discussing the various systems of construction which have been practised in the past and many which are still being installed, but to give you the results of my own practice and experience extending over a period of 21 years, in the hope that the advocates for the various systems or methods opposed to those adopted by me will give their knowledge on this, in order to render my introduction of the subject of more value to the profession generally.

I have had an experience in the construction and repairing of municipal tramways for horse, steam, and electric cars at Bolton, Accrington, Blackburn, and Halifax. Since electric traction came to the front it has caused many alterations in the construction of the permanent way, owing to the cars being heavier and travelling at a greater speed. In the days of the horse cars the track was not of so great moment as at present. The concrete was generally laid first, the rails then laid with fishplates only at the joints and packed afterwards with a mixture of sand and cement, and these have been known to stand without any repairs for many years. Steam traction was next introduced, and this was much more destructive to the permanent way than horse cars, but not, in my opinion, to such a serious extent as the present electric cars, owing to the above reasons, and the weight being distributed over a longer area of track, as, in most cases, there were two bogies to each car and one to the engine.

During the time I was working as assistant under other engineers, four in number, each had a particular fancy for the lines being laid by one of the following methods—viz.: (1) that the concrete be laid first, the metals afterwards, and packed up; (2) that the concrete be laid first, the metals to be put on whilst the same was wet (this I consider a dirty and very unsatisfactory way); (3) that the rails be packed up on blocks, crowed, and the concrete be put in afterwards.

In Halifax, tramways were first laid in the year 1897 for the purpose of running electric cars, and up to the commencement of the year 1900 (the time I was appointed engineer) there had been some 12 miles laid. On these the concrete was laid first, then the metals afterwards, packed up with chippings and cement. The rails were of the girder pattern and weighed about 95lb. per running yard, with fishplates 24in. long, weighing 46lb. per pair, and soleplates 24in. by 8in. by ¾in., weighing 41lb., bolted to the bottom flange of the rail without being anchored down.

Since the year 1900 I have used girder rails weighing 96lb. per yard, with fishplates 25in. long, weighing 70lb. per pair, and anchored down at the joints with Howard Cooper's patent joint, 24in. long, with six rivets into the bottom flange of each rail. This joint block is simply a piece of rail turned the opposite way and the two flanges riveted together. I have also used an intermediate anchor (either one similar to those at the joints, or what is known as the Ames Crosta Bulldog anchor block). As to price of these anchors, there is very little difference. I am strongly of opinion that is better to lay the metals first and the concrete afterwards, and this practice I always carry out. I place the metals on wooden blocks packed up with wedges to the exact level, at intervals of about 9ft. apart, then the line is crowed, afterwards the concrete is packed under the metals and the remainder of the track to the level of the bottom flange of the rail; after this has stood for two days the wooden blocks are taken out and the holes filled in with concrete, and the following day the whole of the crevices under the metals are run in with a mixture of sand and cement (1 to 1). I have had several of the lines tested, but never found one rail in the least hollow. My objection to packing is that men do not pack equally, and this leaves the rail slack in places, which, with the vibration of the cars, causes the setts to lift; and, further, when the concrete is laid first it does not give such an even surface for the paving unless it is skimmed over afterwards, which adds to the expense, and, in my opinion, is not so satisfactory a job.

Since the year 1900 I have laid about 36 miles of track, and have used rails 60ft., 45ft., and a few 35ft. long, but much prefer the 45ft. lengths, for the following reasons—viz.: they are much more readily handled, especially in narrow and steep roads such as exist in Halifax; secondly, there is not the same danger that occurs with the longer rail, the latter very often acquiring a permanent set or hogback by sagging with its own weight, therefore the 45ft. rail is better to pave to and it is much easier to curve. It is true that in the 60ft. rails we have less joints to contend with, which also means less electrical resistance, but to counteract the cost of the joints the 45ft. rail only requires one intermediate anchor, whereas the 60ft. rail ought to have two to each rail, or we find the rail will not sit perfectly solid. The rail used in Halifax is 7in. deep, with a bottom flange 7in. wide and with a tread 2in. wide, groove 1⅛in. wide and 1in. deep, manufactured to the following specification:

*Weight.*—No extra weight over 1 per cent. per lineal yard above the specified weight will be paid for, or no rail weighing more than 1 per cent. per lineal yard less will be accepted; 85 per cent. at least of the rails shall be 45ft. long, the remaining 15 per cent. may be cut from longer lengths with defective ends, to lengths as follows: 5 per cent., 40ft.; 5 per cent., 35ft.; and 5 per cent., 30ft. No variation exceeding ¼in. will be allowed in the respective lengths of the rail. The ends of each rail to be perfectly square, smooth, free from all burrs and other defects, each rail to be coated with boiled oil whilst hot.

*Analysis.*—The chemical proportions in the bloom shall conform to the following: the quantity of carbon shall be 32 to 45 per cent.; silicon not to be more than ·06 per cent.; phosphorus not to be more than ·09 per cent.; sulphur not to be more than ·085 per cent. The blooms are to be free from defects of any kind and regular in quantity. The only metals of which they shall consist shall be iron and manganese, with a bare trace of copper. The engineer shall have power to have samples of the steel from time to time analysed by a chemist, and should these analyses not prove satisfactory, the expense must be borne by the contractor.

*Quantity and Test.*—The rails shall be perfectly straight, free from cracks, burrs, blisters, and other flaws, and of uniform section throughout. They shall show, when broken, a clear, close, and homogeneous fracture. Their ends shall be sawn off perfectly square and machined. The ingots shall be cast of such a size as to leave, when rolled into the finished rail or rails, a crop of at least 1ft. 6in. in length at each end, which shall be afterwards cut off. A piece of rail 5ft long will be taken from each blowing and placed on solid bearings, 3ft. 6in. apart, and the solid bearings shall be fixed on a solid cast-iron block weighing not less than five tons and be well bedded thereon. In order that the rails of that blowing may pass, the test piece shall stand the following test: (1) By a weight of 1,120lb. falling in proper guides upon the centre of each sample from a height of 10ft.

When at the first blow the set shall not exceed ¾in. ...
When at the second blow the set shall not exceed 1½in. } Sample not to be cracked or broken.
When at the third blow the set rail reversed.....

(2) By a weight of 1,120lb. falling in proper guides upon the centre of each sample four times from a height of 20ft., without sample breaking. Every rail shall be stamped with a mark which shall distinguish the blowing of which it formed part. All holes shall be drilled according to drawing, and shall be true and square through the rail.

*Fishplates.*—The fishplates shall be rolled from the same quality of steel in all respects as that specified for the rails. They shall be capable of being bent, when cold, round a bar 4in. in diameter without fracture. It will be noted in the above specification that the percentage of carbon is somewhat lower than in many engineers' specifications, my

* Paper read before the Leeds Local Section of the Institution of Electrical Engineers.

Digitized by Google

reason being that having so many rails to bend on account of the number of curves, we have less breakages than we should have with a higher carbon. The writer has used rails 105lb. to the yard on sharp curves with 1¼in. groove. The engineer must be very careful in the gauging of the rails, or it is a great strain on the wheels of the cars. The gauge on curves should be slightly less, varied according to the sharpness of the curve. I have used both manganese and crucible cast-steel points and crossings, and think the former has a longer life. I have not had any experience in manganese steel-hardened renewable centre pieces, but I do not see any great advantage in them. I use 8ft. 6in. points with 5ft. tongues and 4ft. crossings, except on very sharp curves, then it is necessary to use shorter ones; but the writer would advise that the length of each tongue should be 6in. longer than the wheel base of the car, so that the trailing wheels would be on the tongue before the leaders leave, and then the strain is not so severe. I believe in a fair number of tierods, especially if wood pavement is to be used, or the expansion of the blocks is liable to put the track out of gauge.

*Concrete.*—The mixture I use is five parts of broken gritstone, one of clean sharp sand, and one of best Portland cement, turned over twice dry, then turned twice after water has been added. Formerly the whole of the tracks in Halifax were paved with local stone setts 6in. deep, but now I use nothing but granite or wood, except on the very steep gradients (those steeper than 1 in 10), and even then I use granite for the 18in. margins. The whole of the pavement is run in or grouted with pitch on the level roads to the top of the setts, but in gradients the top ¼in. is grouted in cement. If this is not done, the pitch runs in hot weather and is liable to run down the tread of the rail, which is dangerous for traffic. I laid in 1900 about half a mile of track on longitudinal sleepers, 10in. by 4in. creosoted redwood; it is less rigid, and therefore better for the rolling-stock. These sleepers were embedded in concrete, and the metals screwed down with coach screws at intervals of 4ft. 6in., but my difficulty has been to keep the setts level with the rails, owing to the slight vibration that takes place. If it were not necessary to keep the surface of the road in good condition for vehicular traffic, the writer would much prefer the lines to be laid on timber. The whole of our lines which were laid and were packed up from the concrete have gone badly at the joints and the setts are continually lifting and dropping, owing to the bumping of the cars on the joints, and these lines have constantly to be repacked and repaved. In fact, one line about one mile in length which was filled in with tar macadam I had taken up last year, and found some of the joints down quite 1½in. In relaying this track I welded the whole of the joints on the Thermit process (cutting off the bad ends of the rail and putting in short pieces), and anchored the rails at the joints and centres and paved the surface with granite. This work has proved very satisfactory up to the present. Of course, I may say it is not so perfect as would have been the case had new rails been used, owing, as above stated, to the joints being done and the rails hogbacked, but the road is not a very busy one and will last for years to come. The life of local setts on busy thoroughfares was certainly not more than three or four years, those next to the rail wearing down quite 3in. in that time. I have had little or no repairs as yet on tracks that have been anchored down. It is advisable to use anchors oftener on curves than on the straight, as the rail does not sit so well. The wear and tear on the metals in Halifax is very great owing to the steep gradients, which necessitate the constant use of the slipper brake.

I think it is essential that every engineer having under his control the construction and maintenance of permanent way should have possession of an emery rail grinder. The one in use at Halifax is, I think, up to the present unique, it being the only one of its kind so complete. It was built by Messrs. Ames Crosta and Co., sanitary engineers, Nottingham, specially for Halifax, and is fitted up with an electric motor so that it can travel and work from the overhead wire. It is also fitted with a 12-h.p. petrol motor and can travel and grind from this, if the overhead equipment is cut off, or in case of construction where the same has not been completed. The machine is fitted up with a complete set of drilling apparatus for drilling longitudinally and vertically, or, if required, at any angle, which is very useful and can be run from either motor (Fig. 1). I think it will be admitted that all tramways ought to have been laid to one standard gauge. The question arises, What should that standard have been? At present there is a large percentage of 4ft. 8½in., then comes 4ft., and lastly 3ft. 6in.

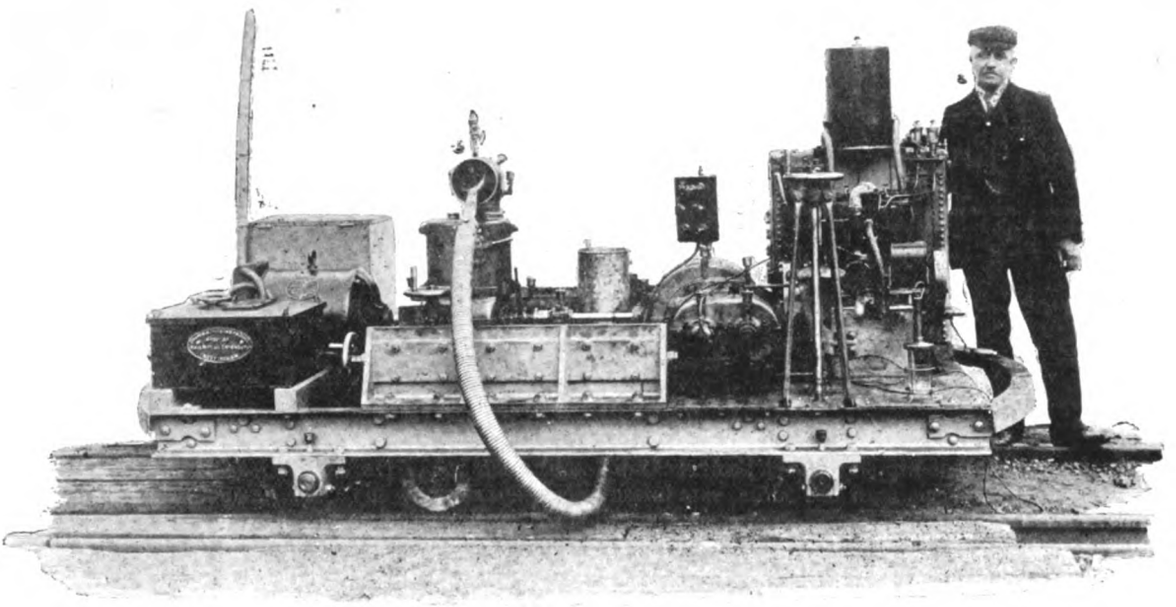

FIG. 1.

One of the points apart from the purely mechanical wear and tear of the tramways which requires the attention of the permanent-way constructor is that of the bonding of the rails, or other means adopted for reducing the electrical resistance of the rails as a return for the current, and it is self-evident that the nearer we get to a continuous rail, the better will be the conductivity and the less danger of electrolysis due to stray current to gas, water, and other metal pipes. It is clear that the welded joint approaches the nearest to the ideal solid way return. I have had some tests made of the electrical resistance of Thermit welding and otherwise, with the following results:

| | Ohms. |
|---|---|
| 1. Taking a solid rail 8ft. long as a standard resistance ..... | ·000067 |
| 2. With Thermit welded joint, without bonds, same length.. | ·000072 |
| 3. With Thermit welded joint, with one bond ..... | ·000067 |
| 4. Fishplates, sole-plate, and two bonds, newly constructed... | ·000078 |
| 5. Fishplate, sole-plate, and two bonds, after two years ..... | ·000095 |

The welded joint has a considerable value mechanically by giving increased strength to the track. In proof of this I may mention that I have made a number of tests and in all instances the rail has broken and not the joint.

The lay-out of the curves is an important item in the maintenance account, as will be gathered from the following instance: I had a curve with a radius of 30ft., the wheel base of the car was 5ft. 6in.; this curve never lasted a longer period than six months, but some 2½ years ago this was altered to a 45ft. radius, and it is little worse to-day. On many of the curves which are 35ft. radius I have to put in a new check rail at intervals of about nine months.

It was my intention to have treated this subject with more detail, but remembering that the paper has been written mainly for discussion by the profession, who have a practical acquaintance with the various points of tramway construction, I have confined myself principally to my own experience and practice, in the hope that various other systems will be brought out and detailed in the discussion to follow.

## ADMINISTRATIVE COUNTY OF LONDON AND DISTRICT ELECTRIC POWER BILL.

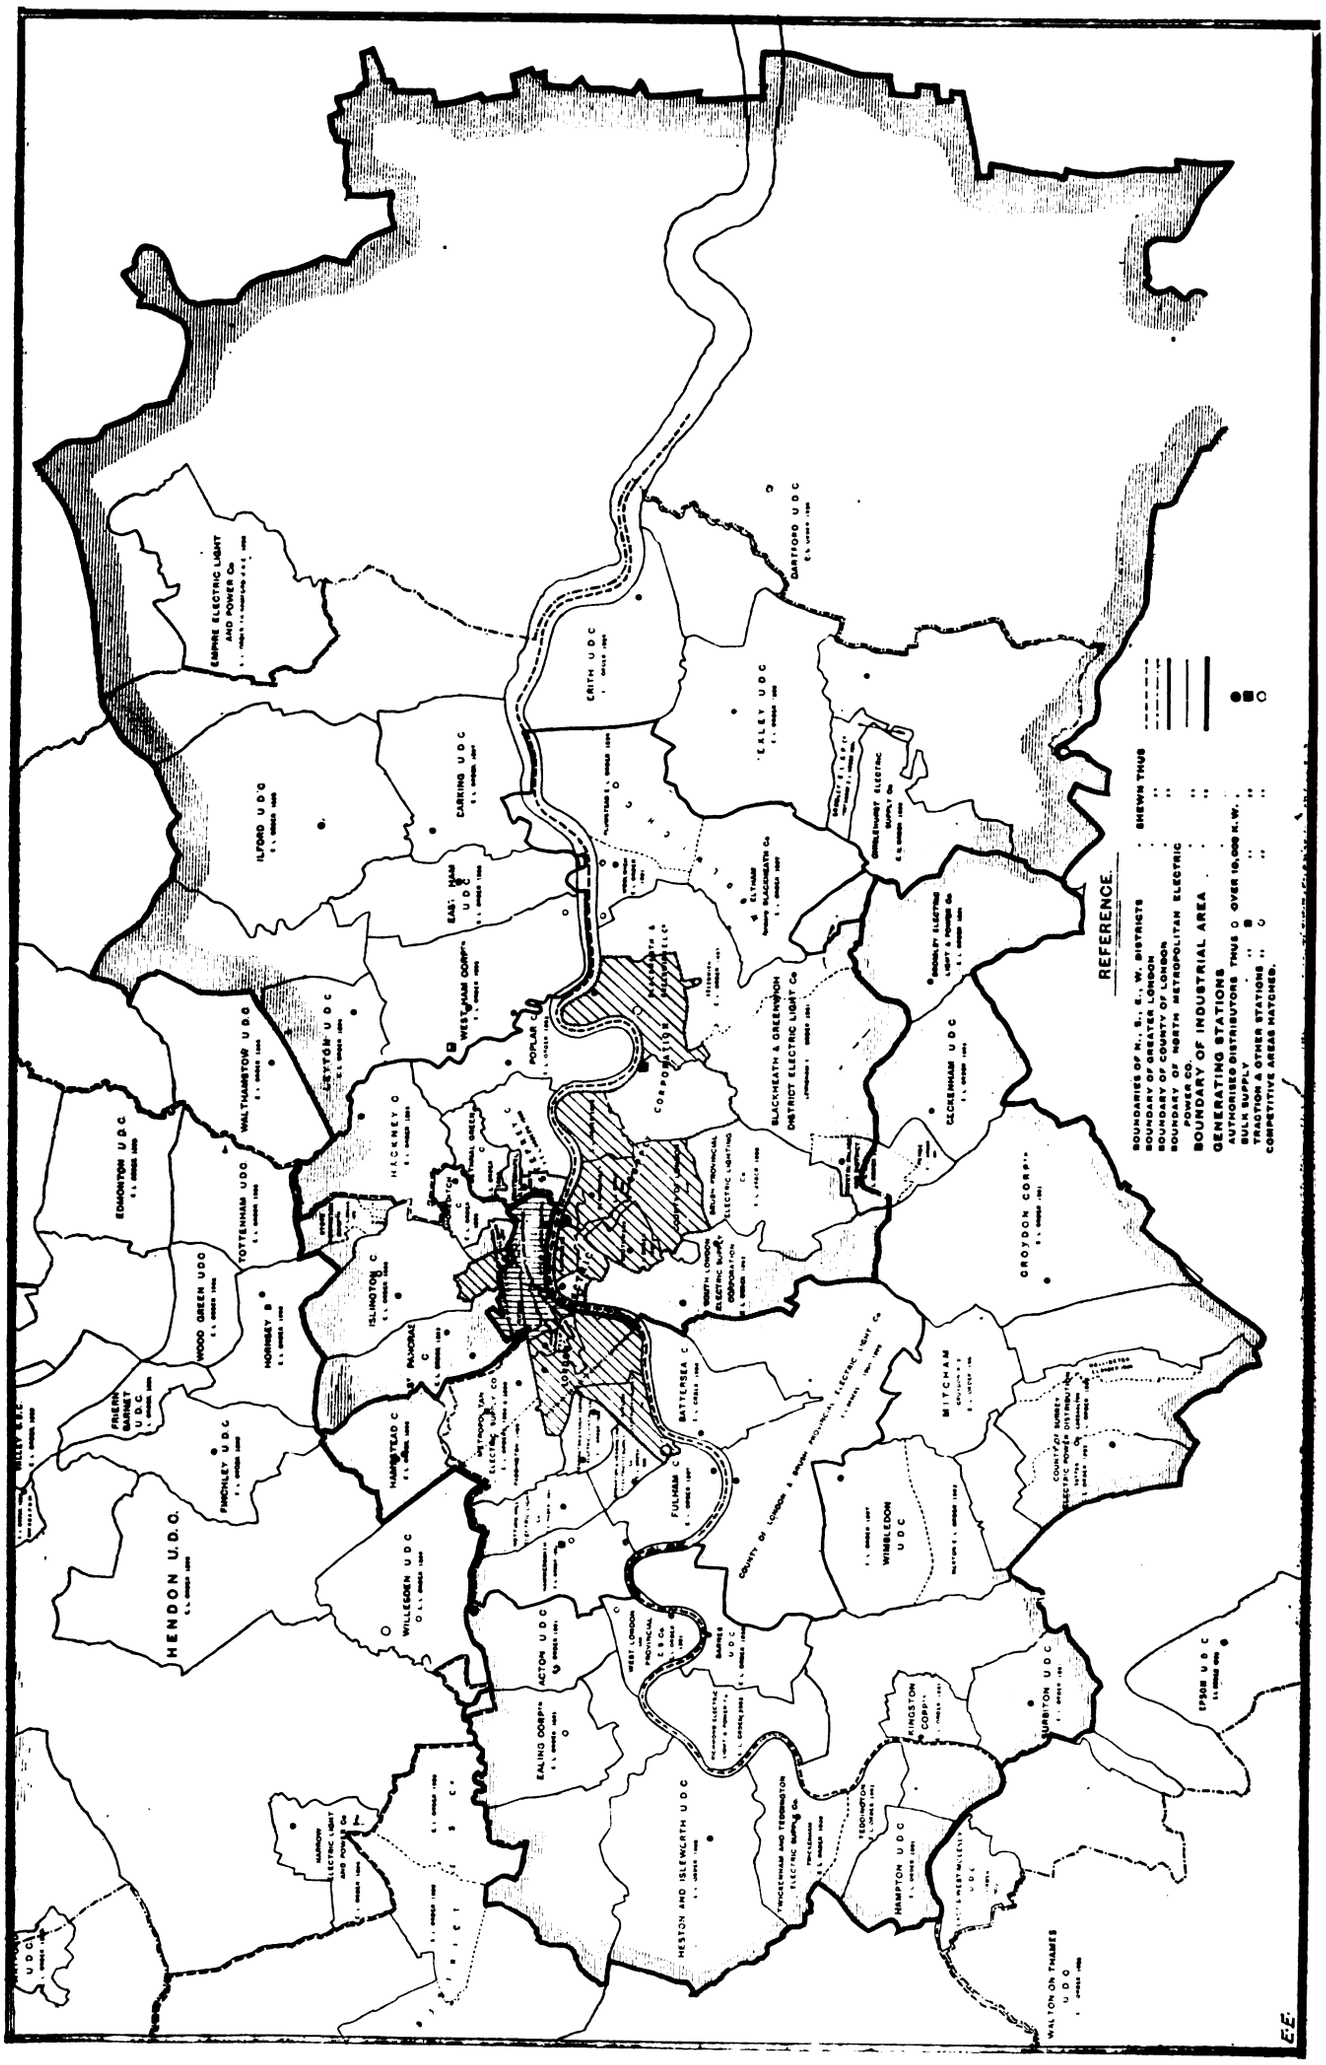
The Select Committee of the House of Lords presided over by Lord Camperdown commenced on the 16th inst. to consider the above Bill. Eight other Bills have been also referred to this committee for consideration, and, in view of the fact that these are more or less in competition the one with the other, it has been decided that the evidence on all shall be heard before any decision is come to. These other Bills are as follows: (2) the East London and Lower Thames Electric Power Bill; (3) the Charing Cross and Strand Electricity Supply Corporation Bill; (4) the City of London Electric Lighting Companies' Bill; (5) the Metropolitan Electric Supply Company's Bill for Acton district; (6) the Metropolitan Electric Supply Company's Various Powers Bill; (7) the North Metropolitan Electric Power Bill; (8) the Central Electric Supply Bill; (9) the County of London Electric Supply Bill.

The first day was devoted to receiving the various petitions against the first-named Power Bill, and to the consideration by the committee of the procedure. After considerable discussion the Chairman announced that they would hear first the evidence on the Administrative County of London Bill by itself.

On Friday, March 17, the case for this Bill was opened by the Hon. J. D. FITZGERALD, who explained the scope of the proposed undertaking. He said that the company was seeking incorporation in order to supply electrical energy for power purposes in the county of London and in certain districts of the counties of Middlesex, Surrey, Essex, and Kent. [This area is shown on the map reproduced on next page.] It was proposed to establish three large generating stations at Greenwich, West Ham, and Fulham, on the banks of the Thames, in positions suitable for getting cheap supplies of coal and a practically unlimited supply of water for condensing purposes. It was intended to generate from these stations electricity at a very low cost, and to supply power to the companies and local authorities already existing, and to other persons if they wished to take it. The area of supply was to be divided into the industrial district and the western, or non-industrial, district. London was the only large industrial area in respect of which a Power Bill of this kind had not been passed. There were at the present time 30 local authorities and 21 companies supplying electricity in London, and they had between them 52 generating stations badly situated in cramped surroundings, incapable of expansion except at enormous cost, and most of them not fitted with machinery suitable for the economical generation of electricity on a large scale. Ninety per cent. of the business of the companies and local authorities was electric lighting. The industrial area embraced in the scheme of the promoters included a large stretch of rural district in view of the tendency on the part of manufacturers to remove their works into the country, where they could get land cheaper, where the rates and taxes were lower, and where they could house their workmen under better sanitary conditions. The only obstacle to this at present was the difficulty of getting an adequate supply of power on cheap terms. The capital asked for was £5,000,000 in shares, and £1,666,000 borrowing powers. Under the clauses of the Bill, the charges for supply by the company were fixed, subject to agreements, etc., that may be entered into, at 1½d. per unit, or, if required by the consumer, at a fixed sum quarterly, not exceeding £1 per kilowatt per quarter of the maximum power required to be supplied, and, in addition, a sum not exceeding ¾d. per unit. In the case of a consumer requiring a supply of electricity for power purposes during eight hours of the 24, this would work out at ·865d. per unit. The expectations of the promoters were based on the experience of the North-Eastern Company, which had now 37 miles of railway in the neighbourhood of Newcastle worked by electricity supplied by the Tyneside Power Company, who also provided the energy for the working of the Tyneside tramways, in both cases much more cheaply than the companies could supply themselves. That there was a magnificent field for electrical enterprise in London on the lines of the scheme before the committee was shown by the fact that a petition had been presented to Parliament in favour of the Bill signed by 350 manufacturers, employing between them 80,000 hands. On Tyneside steam power had been practically superseded by electrical power, 60,000 h.p. under steam having been displaced. There was no reason why similar results should not follow in London from the establishment of a big power scheme.

Mr. C. H. MERZ, examined by Mr. H. Lloyd, gave more particulars of the success of the Tyneside undertaking. He said that the adoption of electricity had resulted in an economy of 40 per cent. over the previous costs for power in shipyards. The manufacturer had also been able to increase his output, save labour, and to carry on his work more economically. As regards the supply of power in London he had prepared Table IV., which shows how far electricity supply had advanced in comparison with other cities at home and abroad. From this he found that London with 5 h.p. per 1,000 head of population had the lowest supply from public undertakers. Table V. was prepared to show what could be done in London, and how small a proportion of the total horse-power in factories is supplied from the public mains. These returns were based on Home Office figures. The industrial area referred to is the eastern portion of the area included in the scheme. These figures showed that the field of electric power distribution had been barely touched. He estimated that in 1911 there would be required some 1,243 million units within the proposed area of supply, of which 380 million units would be needed for power, 296 million units for lighting, and 567 million units for traction. He thought it would pay lighting undertakers to take supply in bulk from the company. To illustrate this he had prepared Table IX, from which it is seen that the average cost per unit generated was 1·92d. He estimated the average charge for supply in bulk from his company would be 1·048d., and for power ·86d. The present stations were much hampered by their positions, which rendered coal more expensive than it should be, and frequently the condensing arrangements were unsatisfactory. As regards the capital expenditure of the proposed undertaking, Mr. Merz gave the particulars given in Table XIII. The revenue account for the proposed undertaking for the year ending Dec. 31, 1910, would be as in Table No. XVI. The question of how the Bill would affect the various existing undertakers was then gone into. Mr. Merz showed that out of 21 companies, 15 lay outside the industrial area of supply. These companies could be supplied in bulk, and the Bill, if passed, would only give competition in the supply of railways, tramways, docks, canal undertakings, or any Government department. Within the industrial area the company could also supply direct to consumers requiring more than 500 h.p. The only competition, however, would be in the event of the present undertaker charging too high a price. From figures prepared for the 12 local authorities now supplying within the area, Mr. Merz found that the cost of production for the year ending March 31, 1904, had been £212,945. In this was included the works cost of generating and the capital charges on land, buildings, and machinery. He estimated that the cost of bulk supply at the maximum

Digitized by Google



Digitized by Google

prices fixed by the Bill would have been £142,137. He considers that these local authorities would be able to reduce their selling prices if they took supply in bulk from his company.

TABLE IV.—Electricity Supply in London. Comparison with Various Cities at Home and Abroad.

| Name of city. | Population. | Horse-power connected per 1,000 head of population. All purposes. | Power only. |
|---|---|---|---|
| Boston | 600,929 | 164·6 | 41·3 |
| Tyneside | 222,241 | 122·8 | 30·0 |
| Frankfurt | 306,000 | 80·1 | 28·7 |
| Berlin | 2,285 000 | 82·1 | 22·0 |
| New York | 3,732,903 | 52·6 | 13·9 |
| Hamburg | 700,000 | 76·7 | 12·7 |
| Glasgow | 785,897 | 43·9 | 8·26 |
| London | 6,565,390 | 48·0 | 5·4 |
| London (industrial area) | 3,812,283 | 25·8 | 4·8 |

TABLE V.—Power Requirements of London, compared with Amount supplied by present Lighting Authorities.

| | | Industrial area. | Proposed area of supply. |
|---|---|---|---|
| 1. Total number of hands employed | 1898 | 458,856 | 609,894 |
| | 1911 | 534,458 | 706,227 |
| 2. Total horse-power installed of all kinds in factories, etc. | 1904 | 456,415 | 592,992 |
| | 1911 | 484 148 | 636,695 |
| 3. Horse-power of motors supplied by present lighting authorities | 1904 | 18,316 | 34,236 |

TABLE IX.—Existing Electric Lighting Authorities. Statistics relating to proposed area of supply, year 1903-4, from Board of Trade returns.

| | |
|---|---|
| 1. Total capital expenditure | £16,598,715 |
| 2. Kilowatts of plant supplied in lighting stations | 181,034 |
| 3. Capital expended on stations | £9,243,982 |
| 4. Capital expended per kilowatt installed | £51 |
| 5. Board of Trade units generated | 159.154.144 |
| 6. Works' costs | £730,332 |
| 7. Works' costs per unit generated | 1·1d. |
| 8. Capital charges on stations | £545,667 |
| 9. Capital charges on stations per unit generated | ·82d. |
| 10. Total generating costs (6)+(8) | £1,275,999 |
| 11. Total generating per unit generated | 1·92d. |
| 12. Gross revenue | £2,345 029 |
| 13. Gross revenue per unit generated | 3·54d. |

TABLE XIII.—Capital Expenditure of Proposed Undertaking. Summarised from detailed table.

| | Works completed. 1910. | 1916. |
|---|---|---|
| Generating stations | £717.200 | £2,615 000 |
| Transmission system | 583.000 | 1,872,000 |
| Sub-stations and distribution system | 401,000 | 1 503,000 |
| Plant on loan | 200,000 | 400,000 |
| | 1,901,200 | 6,390,000 |
| Land and preliminary expenses | 180,000 | 350,000 |
| Total | 2,081,200 | 6,740,000 |
| Less reserve, etc. | — | 500,000 |
| Net capital required | £2,081,200 | £6,240,000 |
| Capital authorised by the Bill | | £5,000 000 |
| Borrowing powers | | 1,667,000 |
| | | £6,667 000 |

TABLE XVI.—Revenue Account for Proposed Undertaking for Year ending Dec. 31, 1910.

| Expenditure. | | Revenue. | |
|---|---|---|---|
| Generating costs: 183.300,000 units at ·154d. per unit generated | £117,617 | By sale of 137,500,000 units at ·7d. | £401,042 |
| Distribution | 23,680 | Sundry receipts | 20,000 |
| | | | 421,042 |
| General expenses, management, rents, rates, taxes, insurance, and sundries | 58,500 | Deduct expenses as stated | 290,337 |
| Selling department | 15,000 | Balance | £130,705 |
| | 214,797 | Which is sufficient to pay 6 per cent. on average capital for the year of £2,000,000 and carry forward £10,705. | |
| Reserve, depreciation, renewals, etc. | 75,540 | | |
| Total | £290,337 | | |

On Monday, March 20, Mr. C. H. Merz, cross-examined by Mr. Balfour Browne, said that while £51 per kilowatt installed was the average cost of the present London station, he admitted that some of these had cost a good deal less. He stood to his estimate of £8·4 per kilowatt for the stations he proposed to erect. He held that there was a large demand for power in London, which was not met because the price was high, and yet that London, owing to its size, could be supplied cheaper than any other place in the United Kingdom. He considered that it would be better to have two or three large stations to give this supply than the 60 to 80 stations now in use. He declined to give the exact figures at which they would supply a suburban railway, but said that the average charge to the North-Eastern Railway for the present half-year was about 63d., including the cost of transformation. The load factor of the supply to this railway was of the order of 35 per cent., and they guaranteed to take at least five million units per year. In the course of cross-examination as to the details of the proposed power stations, tables were handed in from which the following details are taken. Each generating station will contain six turbo-alternators, with a maximum output of 20,000 kw. The most economical load of these turbines will be 10,000 kw. The alternators will generate three-phase current at 12,000 volts and 25 frequency. The boiler-house will contain 48 boilers, in six banks of eight. Thus one bank will supply steam to each turbo-alternator. Heat storage will be provided to enable the output of each boiler to be doubled to meet the conditions of peak load. Seven boilers will under these conditions be able to supply steam for the maximum load on a turbine. The steaming capacity of each boiler will be 30,000lb. per hour at the most economical load. The normal capacity of the plant installed in each station will be 90,000 kw. with a maximum of 120,000 kw. for short periods. As regards the system of transmission and distribution, it is proposed to adopt the 'bus-bar ring system. Main supply cables would be carried through the northern and southern portions of the area to form a ring surrounding a portion of the river. The ring would be supplied from generating stations situated on the river at diametrically opposite points and a sufficient number of alternative routes (four from the east and two from the west) would be used to ensure the full maintenance of supply even in the event of the breakdown of one entire route. An inter-connector crossing the ring about midway between the generating stations would also be laid, thus combining the cables on the two sides of the river, and providing additional safety thereby. Main distributing centres would be spaced along the ring from which the tributary cables would radiate, and at which points the main cables would be sectionalised. In designing the tributary system, the chief aim would be to provide duplicate routes to every sub-station, with the ends of the loop fed from different main distributing centres on the 'bus-bar ring. In the low-tension network there would be no disconnecting boxes used in the streets. Other details of design were given to show the standard sizes of apparatus employed. For instance, the 12,000-volt cables would be three-core ·25 square inch, the transformer units would be either 500 kw., 1,000 kw., or 1,500 kw. capacity. The low-tension cables at 600 volts would be either ·25 or ·1 square inch section. He claimed increased economy in working due to the small number of large generating units which there would be in the station. It would not pay to put up large generating stations with 40 or 50 units of plant. He did not think there was any objection to scrapping existing generating stations if a gain was made in the yearly revenue account of the present undertaker. He supported his estimate of £8·4 per kilowatt of plant by the cost of the Carville power station on the Tyne. Here, with a peak capacity of 15,000 kw., the cost averaged £10 5. He also gave the cost per Board of Trade unit generated at this station for the last six months. Thus for February the low figure of ·120d. was obtained. With the increased cost of coal on the Thames he estimated the cost would rise to ·15d. per unit generated. He estimated that the cost of Tyne coal delivered at the London stations should average 8s. 6d. per ton.

## APPOINTMENTS VACANT.

**Chief Electrical Engineer,** Bermondsey Borough Council.

**Traffic Superintendent,** Rotherham Borough Council. £130 per annum.

**Greenock.**—The number of units generated for the five weeks ending Feb. 4 was 217,234 as compared with 169,725 for the corresponding period of last year, being an increase of 47,509 units.

## THE SCRAP HEAP.

The question of scrapping has been discussed again and again, but it is continually cropping up, and plays a very important part in the controversies now raging. The question would not be so important if it did not involve that of municipal trading. The world is very hard—it praises success, but does not tolerate failure. Sympathy in commercial matters is a negligible quantity, and capital risked and lost has for practical purposes passed out of consideration. The private individual who loses his capital has no further place in commercial affairs, and the company which goes to smash is heard of no longer than it takes the courts to realise and distribute the assets. A municipality is hardly in the same category. It is just possible that it could become bankrupt, but it is very difficult to see how a final whitewashing to the absolute loss of creditors can take place while rates can be exacted that more than cover ordinary expenses. During the parliamentary enquiry relating to this year's Bills one of the prominent witnesses suggested that probably all the existing or, at any rate, most of the existing stations would be scrapped. Quite recently we pointed out, and it will not be out of place to recur to the subject again, that the question of scrap—or not to scrap—was in the abstract simple, but simplicity in the concrete is not so certain. Take any example, say, with a capital expenditure of half a million. This capital is used to provide something to sell, and out of the selling price (assuming success) all outgoing expenses have to be paid, including interest on capital, and if a municipality repayment of capital. We need not labour to mention every item, nor to discuss supply and demand—the latter is assumed. If a company or municipality deal in a monopoly, progress does not so much affect it. If, however, there is competition, then progress can ruin their concern by bringing into competition something that produces equally good results at a lower cost. This is all elementary knowledge, and if losses are merely losses, the world looks on and goes about its concern without recognising that anything out of the ordinary has happened. Another failure, that is all. Under the concrete conditions existing that is not all. A municipality that embarks half a million in business has to pay that half a million, and cannot lose it for the creditors in the ordinary acceptation of the term. When, then, can a municipality accept the inevitable and scrap its business premises? If progress provides a means so that it can purchase what it wants at a cost so much below its own cost of production that the difference will enable it to pay interest and annual instalments on capital, it might be said to be justified in buying in bulk and not generating. The concrete case, however, is far less simple. The purchasers want to participate in the reduction brought about by progress, and unless there exists a monopoly will insist upon such participation. If competition exists, the capital expenditure goes, and the ratepayers have to pay interest and annual instalments upon the capital lost. There seems to be no third way; either the purchasers have to pay a much higher price for what they buy than the conditions of progress warrant, or the ratepayers have to pay for having embarked in a business that has turned out to be a loss. All this assumes the reality of the progress, and there is no reason to doubt the correctness of the assumption up to a point. It has not been proved, however, that size of installation is effective in decreasing cost past a certain point. Hence progress does indicate scrapping except in certain cases, and each particular case has conditions which prevent generalisation. The fact remains, however, that it will not pay to buy in bulk when loss cannot be con-

Digitized by Google

templated unless the users are satisfied not to participate in progress, or to participate to a smaller extent than the facts of the case really warrant. The arguments often put forward usually simply imply loss, which the ratepayer must be prepared to pay. The mere fact that it is cheaper to buy in bulk is no consolation to the ratepayer or the consumer. The liability incurred by law remains, and must be met. There has as yet been no method suggested whereby a municipal trading concern can play fast and loose with other people's money, and until such concerns are placed in a position similar to other trading concerns, the question arises which has never yet been met—that either the consumer or the ratepayer pays that which, under all other trading conditions, would be the loss of creditors. This is good for creditors.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### AUXILIARY RAILWAY SIGNALLING.

SIR,—Referring to letter from "Explosive" which appeared in your issue of March 10, we fully agree with him that all automatic signalling has the insuperable objection, that personal responsibility ceases by its use, and the failure of the electrical system was in a measure the cause of the recent French accident. The last paragraph of his letter suggests an emergency signal, to be under the direct control of the signalman in his box, one simple in both working and construction.

A client of ours has recently patented such an apparatus which would in every respect seem to comply with these requirements, and we shall be pleased to supply particulars of same to anyone interested therein.—Yours, etc.,

Cardiff, March 18, 1905. AITKEN AND Co.

### ELECTRIC TRAMCARS AND MOTOR 'BUSES.

SIR,—Your leader last week on the question of the electric tramcar *v.* the motor 'bus was most informative, and certainly Mr. Salter seems to have made out a very good case for our own side of the industry; but where I think the advocates of the motor 'bus make a great mistake is in basing their figures and arguments from the point of view of the *petrol* motor 'bus.

Now, I think it cannot be gainsaid that from a non-technical standpoint the petrol 'bus is not in it at all in comparison with the steam 'bus. In my opinion, the steam 'bus, from the point of view of the general public, is almost as far ahead of the petrol 'bus as the latter is of the old-fashioned horse vehicle. I have travelled in both types of vehicle since they have been put on the London streets, and whilst greatly impressed with the smooth and quiet running of the steam 'bus, I was much disappointed with the petrol type. The vibration and smell of the latter at stopping points was most unpleasant, and every start was a series of jerks.

Let us take a few points only in which the steam 'bus scores over its rival: (1) absence of smell; (2) absence of vibration; (3) smoothness in starting (its acceleration curve *is* a curve, not a zigzag); (4) greatly reduced noise.

There can be no doubt that, as far as the passenger and the man in the street is concerned, the steam 'bus is infinitely preferable. Granted this, the question before us is whether the steam 'bus can be worked more economically than the petrol 'bus.

I do not know whether any figures have been published as regards running costs of the steam 'bus. Possibly, as in the case of light cars, the steam 'bus takes more petrol to fire its boiler than the petrol engine itself uses. Against this can be put the lower grade of petrol used, and also there must be a considerable saving in lubricating oil. Where the steam car should score is in maintenance and depreciation charges. On the one hand, we have a simple smooth-acting steam-engine, driving direct, and throwing comparatively slight strains on its mechanism; and on the other hand a complicated explosion engine, which must be kept constantly running, start or stop, and with all the complications of gears and clutch. In every one of the hundreds of stops and starts these 'buses have to make the change through the two speeds must be made, and the wear and strain on the vehicle and tyres is in direct proportion to the skill, or want of skill, of the driver. It must always be a serious item.

It is for these reasons that I think the steam 'bus should prove far less costly to maintain than the petrol 'bus, and will accordingly prove a far more serious competitor to the electric tramcar than the petrol 'bus in its present development.—Yours, etc., M. F.

### MR. MARCONI'S LECTURE.

SIR,—It is interesting to note that Marconi is getting his speed up. We have been sending and receiving wireless messages at 25 to 45 words a minute for several years. The compliment to the expertness of our operators quite overcomes us.—Yours, etc., F. Z. MAGUIRE,

American De Forest Wireless Telegraph Company.

5, Warwick-court, High Holborn, March 16, 1905.

## NATIONAL PHYSICAL LABORATORY.

The annual inspection of the National Physical Laboratory took place on Friday last week, when a large number of gentlemen accepted the invitation of Sir William Huggins, president of the Royal Society, and Lord Rayleigh, president of the General Board, to be present. Dr. Glazebrook, the director, and his assistants explained the uses of the various appliances installed. The most interesting addition recently made to the equipment of the laboratory is, perhaps, a machine for measuring internal diameters by comparison with a known standard. It seems to be in a more or less experimental stage at present, but should be capable of extremely useful service.

Among the researches of more general interest concluded during the year are the following: An investigation for the Engineering Standards Committee into the properties of insulating materials at the temperatures ordinarily reached in generators and motors, and a study of the distribution of temperature in the coils of such machines. An examination of the allowances necessary to secure proper working between the running parts of machinery. An investigation into the properties of different qualities of guttapercha. Photometric and life tests of incandescent lamps under various conditions. An investigation into the methods of obtaining and measuring high temperatures of 1,800deg. C to 2,000deg. C. The erection and testing of a standard lathe for cutting leading screws for large lathes to a very high order of accuracy. An examination of the properties of nickel steels, prepared for the work by Mr. R. A. Hadfield. The construction of the electrical parts of a standard balance for the measurement of an electric current. The construction of a machine for examining the effect of rapid alternations of stress on materials used in engineering practice. In addition to these and other researches which have been successfully carried through, a number of enquiries have been declined for want of sufficient equipment. The committee hope that this may, however, be shortly remedied.

The programme for 1905 is equally varied as far as the character of the researches is concerned. Electrical engineers will be interested in the investigations on superheated steam to be carried out in the engineering department.

In the physics department, besides work on standards, a series of magnetic tests on iron are to be undertaken, with a view of obtaining, if possible, a non-ageing material with low hysteresis loss. For this purpose a firm of leading manufacturers is preparing a large number of samples in the form of rings and strips. One set of these samples are to be of uniform chemical composition, but submitted to various courses of heat treatment. Another set is to be of varying chemical composition, all annealed similarly, while a third batch is to include typically inferior material. A

Digitized by Google

large electrically-heated oven is ready, and in this the various samples will be submittted to steady temperatures. At intervals hysteresis tests will be made. After examination of the first set of results it is probable that some, if not all, of the samples will be submitted to reannealling or other heat treatment, and after this the ageing tests repeated. It is hoped that in this way some clue will be obtained to the conditions which determine the magnetic quality of the material as regards ageing.

In response to a request from the Engineering Standards Committee, a series of tests on the distribution of temperature in transformers, similar to those already made on dynamos, is being undertaken with the co-operation of various prominent firms which have constructed special transformers for the work. Thermo-junctions of iron-eureka have been embedded in these, and will allow the temperature to be measured at various points. Determination of the efficiency of the transformers will also be made.

Other departments have an equally full programme. The representative gathering at the laboratory on Friday last showed great interest in the work in progress, which is of national importance.

## ELECTRICITY SUPPLY BILLS.

A conference, convened by the London County Council, was held on Monday at Spring-gardens, under the presidency of Mr. Cornwall, chairman of the Council, to consider what steps should be taken in reference to the Electricity Supply Bills now before Parliament. A large number of the metropolitan borough councils and the City Corporation were represented.

The CHAIRMAN, in opening the proceedings, alluded to the industrial progress of electricity, and to the necessity of safeguarding the interests of the public. He quite appreciated the advantage of securing the cheapest possible supply, but believed that, everything considered, this was most likely to be provided by the County Council and the borough councils. He reviewed the Bills introduced by the County Council in 1898 and 1901 to constitute it the supply authority for the Metropolis subject to certain conditions. The immediate object of the conference, however, was to arrange for united action in opposing the various companies' Bills so as to preclude monopoly.

A representative of the Council's parliamentary department having defined the position of matters before the Lords Committee, Mr. A. J. SHEPHEARD, vice-chairman of the Council's Parliamentary Committee, expressed the opinion that the effect of the Administrative County of London Company's Bill would undoubtedly be to create a monopoly. The company might say they had no such intention, but by increasing their capital their operations would become so extensive and their foothold so strong that they could defy competitors to oust them. Discussing the line of opposition that should be taken before the Lords Committee, he considered that, owing to the suddenness with which the matter had confronted the municipal authorities, the County Council could not at the present moment present an alternative scheme. He, therefore, advocated that application should be made for the postponement of the Bills until next session, in order to give the local authorities an opportunity of investigating the details and formulating their case against the Bills.

Mr. DEWEY (Islington) agreed with the previous speaker that the present moment was not opportune for the conference to discuss details, as the matter was urgent. He consequently moved the following resolution: "That this conference of the London County Council and metropolitan borough councils is of opinion that in the interests of the Metropolis the whole of the Electric Supply Bills now before Parliament should be strenuously opposed."

Mr. LYON (Hampstead) seconded.

The delegates from Finsbury and Wandsworth said they were substantially in accord with the resolution, but as their districts were dependent upon one of the companies for their electric light, they would be compelled to except that company from their opposition.

Mr. A. C. MORTON (City of London) strongly supported the resolution, declaring in emphatic terms that they had too many companies already.

Mr. ROBINSON (L.C.C.) observed that if reservations in favour of certain companies were to be made when resisting the Bills, there would be great danger of the opposition failing. He therefore appealed to the conference to give their whole-hearted support to the resolution.

After other speakers had briefly expressed their views, Mr. Dewey's motion was put to the vote and carried *nem. con.*

The conference then adjourned pending the decision of the Lords Committee.

## GLASGOW CORPORATION ELECTRICITY DEPARTMENT.

### Appointment of Chief Engineer.

At a meeting of the Glasgow Corporation held on Thursday, 16th inst., Mr. W. W. Lackie was unanimously appointed to succeed Mr. Chamen as chief engineer of the department. It will be remembered that Mr. Chamen has accepted an important appointment with the firm of Messrs. Bramwell and Harris, consulting engineers.

Mr. William W. Lackie was born 36 years ago, and is the son of Mr. David Lackie, iron merchant and iron-founder, Montrose, Forfarshire, who was provost of Montrose for three years. Mr. Lackie received his elementary education at Montrose Academy and the Aberdeen Grammar School. After leaving the grammar school Mr. Lackie went through the engineering course at University College, Dundee, under Prof. Ewing (afterwards of Cambridge), attending the classes for mechanical engineering and electrical engineering during the three sessions 1885 to 1887. The next year was spent in the laboratory of Lord Kelvin at the Glasgow University. Mr. Lackie then turned his attention seriously to practical work by entering the service of Messrs. Mavor and Coulson (then Messrs. Muir, Mavor, and Coulson), of Mile-end, Glasgow. That firm had then already come to the front in Scotland as electrical manufacturers, contractors, and supply undertakers, a position which in the two former respects at least they still continue to hold; and Mr. Lackie on entering their service was soon in the midst of some of their most important work, being employed at the wiring of the municipal buildings of Glasgow and several of the largest warehouses in the city. It was while with this firm, also, that Mr. Lackie had his first introduction to central-station work, being for four years frequently employed in the Miller-street generating station, which at that time supplied current to the General Post Office and several other large concerns. About that time also he had the good fortune to be connected with the erection of his firm's high-tension station in John-street. This station was the first real generating station for the supply of electricity to private consumers in the central area of Glasgow, and it is this station which was bought up by the Glasgow Corporation in 1892, and formed the foundation of the present electricity department. Mr. Lackie was appointed mains superintendent of the new venture, and has since remained in the service of the Glasgow Corporation. He superintended the laying of the whole of the underground mains under the scheme for which Prof. Kennedy was consulting engineer, and when Mr. Chamen came to Glasgow in 1898, he remarked at a public function organised by the officials of the electricity department on the occasion of Mr. Lackie's marriage, that he considered the Glasgow electricity mains as laid under Mr. Lackie's superintendence were in a state of excellence second to none in the United Kingdom. In 1897, the Electricity Committee recognised Mr. Lackie's abilities by promoting him to be chief assistant to Mr. Arnot, who

Digitized by Google

was at that time chief engineer, and during Mr. Chamen's tenure of office as chief engineer (from 1898 up to the present time) Mr. Lackie has continued to hold that position. Mr. Lackie is the author of various papers on those branches of his subject which more immediately concern him, among these being a paper on "Underground Mains in Glasgow," communicated to the Physical Society of the Glasgow University in 1895, a paper on "Systems and Methods of Charging for Supplies of Electrical Energy," read before the Glasgow Local Section of the Institution of Electrical Engineers and a paper on "Earthing," also read before the same society—the two latter having been accepted for insertion in the *Proceedings* of the parent institution. During the past winter Mr. Lackie has delivered a special course of lectures on electric lighting and wiring in the Technical College, Glasgow. These lectures have been largely attended and well received.

Mr. Archibald Page, at present station superintendent, has been unanimously appointed to the post of chief assistant engineer, rendered vacant by Mr. Lackie's promotion. Mr. Page is 31 years of age, and is a native of Alloa, N.B. He received his elementary education at Dollar Academy, and his technical education at Heriot-Watt College, Edinburgh, and the Technical College, Glasgow. He served his time as a mechanical engineer in his native town. He entered the Corporation service about six years ago, and has in the interval gained rapid promotion through sheer force of ability.

Mr. R. B. Mitchell, resident engineer at the department's Port Dundas electricity works, has been appointed mains superintendent.

## THE HOLBORN AND FINSBURY ELECTRICAL EXHIBITION.

The Holborn and Finsbury Electrical Exhibition (118-122, Holborn), organised by the County of London Electric Supply Company, Limited, was opened at 11.30 on Monday, March 21, by Alderman Fitzroy Doll, the mayor of Holborn. A large and representative gathering of the aldermen and councillors of the various boroughs associated with the County of London Company (Holborn, Finsbury, Wandsworth, Camberwell, Bermondsey, and Southwark) were present, together with a very large number of the leading electrical engineers and representatives of the manufacturing and trading firms.

The MAYOR, in opening the exhibition, referred briefly to the big strides which the electrical industry has made during the last few years, and dwelt particularly on the recent developments of the use of electricity as applied to driving machinery. The latter, he insisted, were of such fundamental importance to manufacturers and users of powers that none could afford to do other than give the matter a serious consideration.

The MAYOR OF WANDSWORTH spoke in support, and mentioned that it was in his own borough that the most expensive operations so far as lighting is concerned of the company were carried on. He emphasised particularly the widespread benefit which resulted from the company's slot-meter scheme, by which houses were wired by the company free of initial cost, and cited the case of the London County Council cottages at Totterdown, Tooting, which were lighted under this arrangement.

Alderman E. C. TRIPP then spoke, followed by Mr. J. B. BRAITHWAITE, jun. (the chairman of the County of London Electric Supply Company, Limited), who referred to the remarks of the Mayor of Holborn as regards the uses of electric energy for driving machines, and pointed out that this side of the undertaking of the company was made an especial feature, and cited the fact that together with the City of London Company they supplied more than 20,000 h.p. for power purposes. He thought that this was a good answer to the ambitious scheme for the supply of power in London being considered by the House of Lords Committee. The engineer of this scheme proposed to show the London companies how to do their work. He thought they had nothing to learn from the proposed undertaking.

The exhibition itself is an exceedingly well-organised one, and most of the leading electrical firms are represented. There are no less than 55 stall-holders, and the range of exhibits is exceedingly wide. The promoters of the exhibition have organised two or three special exhibits to show the latest developments in domestic lighting and heating. A great feature is the large number of street-lighting appliances which are on view. These range from the ordinary incandescent lamp up to the latest form of mercury vapour lamps, exhibited respectively by the British Westinghouse Company and Mr. Bastian. Arc lamps are shown by a large number of firms, and the recent types of flame lamp show marked advances which have been made for securing higher efficiency with this type. The exhibits of motive power form, in our opinion, the backbone of the show. Motors are shown driving a great variety of mechanical tools and as applied to electric lifts, hoists, and other special work. Intending users of power will thus find in the exhibition useful hints on the latest methods of driving all classes of machinery.

So far we have only referred to the exhibition as one of interest to would-be consumers. There are, however, in many of the exhibits more features of interest to the electrical engineer himself; for instance, several of the large cable companies have well-organised exhibits to show their latest type of cables and accessories. The exhibition is one which is likely to remain open for some time and which will well repay one for a visit. We propose to refer to specialities to be seen on individual stands in our next issue.

## TEMPERATURE CURVES AND THE RATING OF ELECTRICAL MACHINERY.*

BY RUD. GOLDSCHMIDT, ASSOCIATE MEMBER.

*(Continued from page 377.)*

An enlarged temperature curve is given in Fig. 4, which can be used on any given scale by simply choosing the

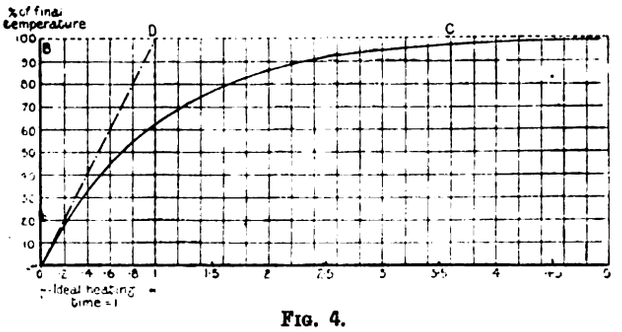

FIG. 4.

scale of temperatures so that O B is equal to the final temperature, and the scale of time so that $\frac{O\,B}{B\,D}$ is equal to the initial temperature increase. B D is the time in which the body would have reached the final temperature if no cooling had taken place during the period. In our example the initial rise per minute is $V = 0{\cdot}55$deg. C., and the final temperature is $tf = 50$deg. C. Therefore the "ideal heating time" B D is $\frac{50}{0\,55} = 90$ minutes $= 1\frac{1}{2}$ hours. To the ideal heating time we will give the symbol $T_i$.

$$T_i = \frac{tf}{V} = \frac{W_s}{C_h} \cdot \frac{C_v}{W_v} = \frac{\text{Watts}}{\text{Surface}} \times \frac{C_v}{\text{Watts}}.$$

$$T_i = \frac{\text{Volume}}{\text{Surface}} \times \frac{\text{Rise constant}}{\text{Heating constant}}.$$

$T_i$ is dependent only on the constant of the apparatus and on the ventilation, and is independent of the watts lost. This will be the basis for all our further calculations; for instance, in order to determine the very important practical question, after what length of time will a given machine approach its final temperature within a few per cent., we have only to examine the curve in Fig. 4, which

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

shows that the final temperature is attained within 5 per cent. at the end of three times $T_i$, the ideal heating time. For a commercial temperature test this time ought to be sufficient, as the temperature would be raised only 1½deg. more after another hour, assuming the final temperature to be 50deg. C. A table giving the constants of this curve is appended:

TABLE V.

| Time of heating. Unit: ideal heating time. | Per cent. of final temperature attained. | Time of heating. Unit: ideal heating time. | Per cent. of final temperature attained. |
|---|---|---|---|
| 0 | 0 | 1·25 | 71·5 |
| 0·1 | 9·5 | 1·5 | 77·8 |
| 0·2 | 18·1 | 1·75 | 82·8 |
| 0·3 | 26 | 2 | 86·6 |
| 0·4 | 33 | 2·5 | 92 |
| 0·5 | 39·5 | 3 | 95·5 |
| 0·6 | 45·2 | 3·5 | 97·3 |
| 0·7 | 50·5 | 4 | 98·4 |
| 0·8 | 55·1 | 4·5 | 99 |
| 0·9 | 59·5 | 5 | 99·5 |
| 1 | 63·3 | — | — |

On examining Fig. 3 we notice that the projection of the different tangents O D $e-10^1$, $f-20^1$, $g-30^1$, etc.—viz.,

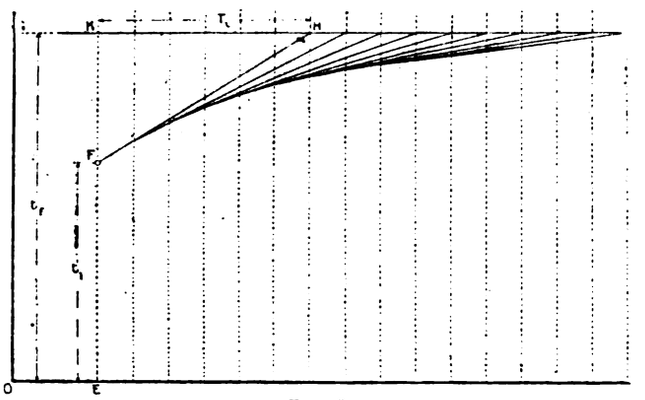

FIG. 5.

B D, $e^1-10^1$, $f^1-20^1$, $g^1-30^1$, etc.—are all equal to the ideal heating time, $T_i$. This fact enable us to construct the temperature curve starting at any point. Assuming the apparatus to be at an initial temperature, $t_1$, before starting the actual temperature test, and if the final temperature, $t f$, and the ideal heating time, $T_i$, are known, we can construct the temperature curve on the basis of the assumption that the air temperature is $t_1$ degrees higher. Make (Fig. 5) E F = $t_1$, O G = $t f$, K H = $T_i$, draw F H, and continue the construction as explained with reference to Fig. 3. In order to find the time when the final temperature will be reached within a certain percentage, Table V. can be used.

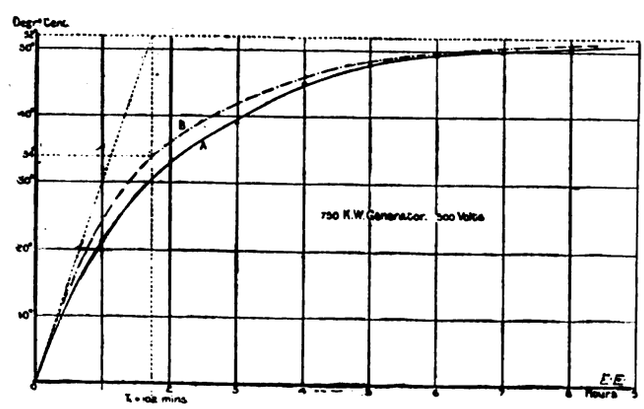

FIG. 6.

To find the time in which the field coil considered above will reach 47½deg., starting with a temperature of, say, 30deg. C., we need only consider the air temperature to be 20deg. higher, or the field temperature to be 20deg. less—that is, 50 − 20 = 30deg. C. = total range of rise = $t f^1$. The temperature under consideration—viz., 47½deg.—becomes 47½ − 20 = 27½deg. The latter as a percentage of the new $t f^1 = \frac{27\frac{1}{2}}{30} = 0{\cdot}92$. From Curve 3 or Table V. we observe at once that 0·92 of the final end temperature is reached in $2\frac{1}{2} \times T_i = 2\frac{1}{2} \times 1\frac{1}{2} = 3\frac{3}{4}$ hours.

A very useful rule for determining the length of time of the temperature test of a machine can be deduced as follows: It is only required to know (1) what the final temperature is likely to be and (2) the current density. The initial temperature rise is proportional to the square of the current density. In our example we had 1·7 amperes per mm.² (1,080 amperes per square inch) and an initial rise of 0·55deg. C. per minute. For 50deg. C. the ideal heating time, $T_i$, was 1½ hours. From this we can calculate tables of the ideal heating time, $T_i$, say for final tempera-

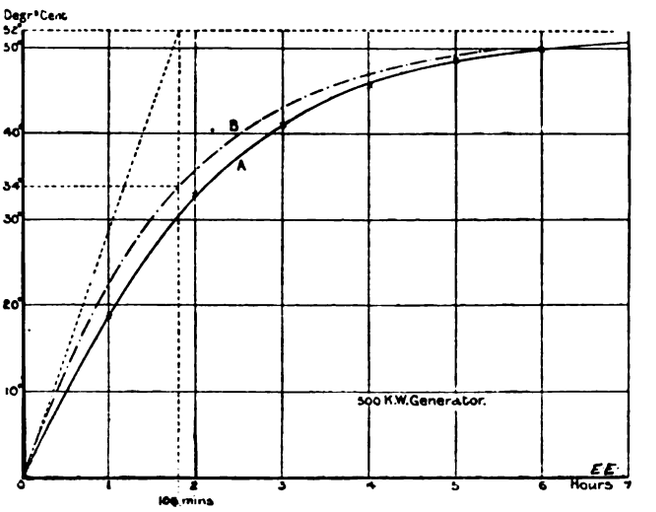

FIG. 7.

tures of 50deg. C. and 75deg. C. (measured by resistance rise).

TABLE VI.

| Current density: Amps. per square millimetre. | Current density: Amps. per square inch. | Ideal heating time in minutes for a final temperature of: 50° C. (90° F.) | 75° C. (135° F.) |
|---|---|---|---|
| ·25 | 160 | 4,200 | 6,300 |
| ·5 | 320 | 1,040 | 1,550 |
| ·75 | 480 | 460 | 690 |
| 1 | 640 | 260 | 370 |
| 1·5 | 960 | 115 | 173 |
| 1·56 | 1,000 | 107 | 160 |
| 2 | 1,280 | 65 | 97 |
| 3 | 1,923 | 29 | 43 |
| 5 | 3,200 | 10½ | 16 |

The application of Table VI. may be shown by some examples.

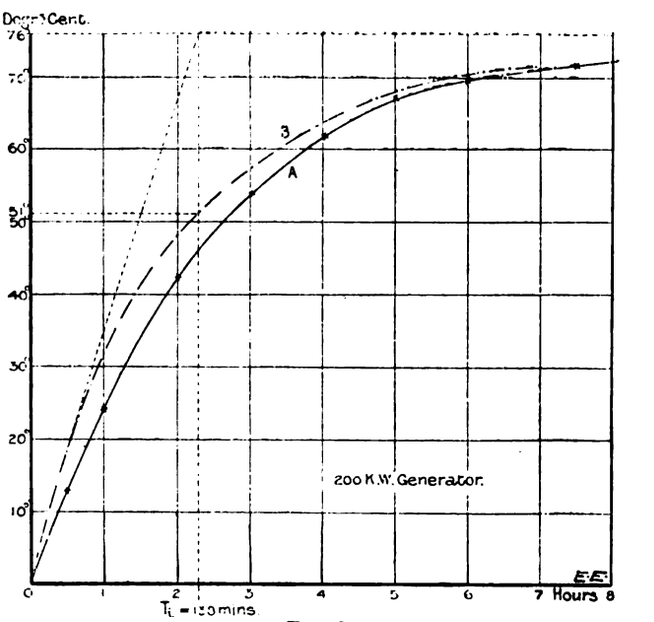

FIG. 8.

*Example* 1.—A continuous current machine is designed for 50deg. C. final temperature rise. The current density in the field coils is 1,000 amperes per square inch. How long is it to be tested in order to produce a rise of temperature equal to 95 per cent. of the final temperature?

Digitized by Google

Due to its considerably smaller heating constant, the armature has, as a rule, reached the end of its ideal heating time, $T_i$ (see formula for $T_i$), and in consequence its final temperature, more quickly than the field coils have. Therefore the field coils determine the time of test for a continuous-current dynamo, and if their temperature is practically constant, one can be sure that of all other parts is also constant.

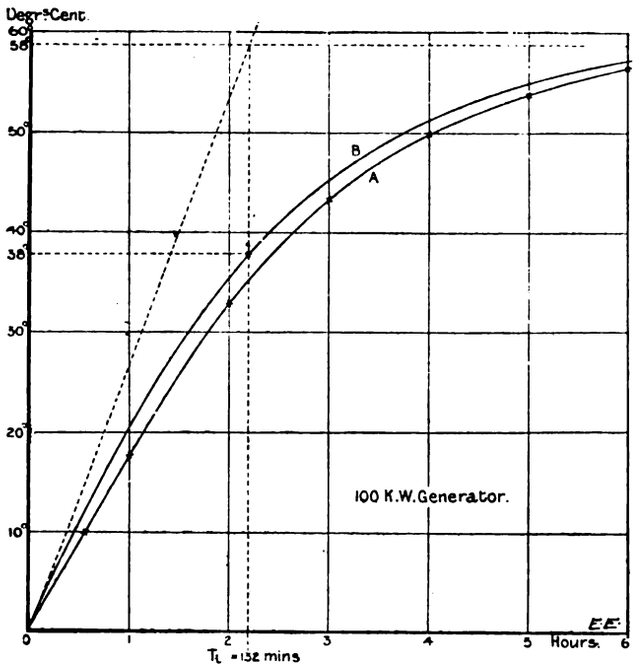

FIG. 9.

From Table VI. we take $T_i = 68$ minutes for 1,250 amperes per square inch, and from Table V. the time of test necessary to bring the parts within 5 per cent. or 2½deg. C. of their final temperature is $3 \times T_i = 3 \times 68 = 3\frac{1}{2}$ hours. If we were to test this machine for only a little over 2 hours $= 2 \times T_i$, only 86 6 per cent. of its final temperature would be reached. In further illustration of this example, which is of great practical importance, some temperature curves of "Crompton" continuous-current machines are added (Figs. 6 13).

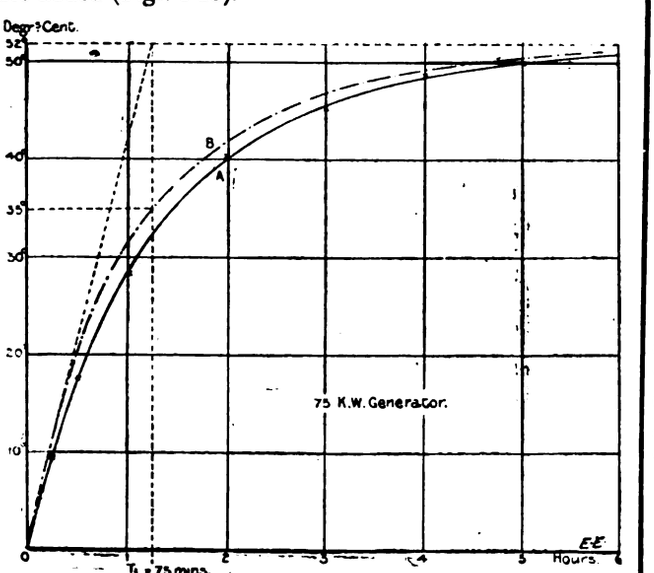

FIG. 10.

Fig. 8, for instance, refers to a 100-kw. open type 440-volt dynamo with a current density of 1·25 amperes per mm.² (830 amperes per square inch) in the field when hot. The Curve A is the curve actually observed, the Curve B for constant final loss being developed from A for the reason that during the test the exciting current was kept constant, and in consequence the loss in the field increased with the heating up of the copper. We see that the final temperature rise is 58deg. C. (measured by resistance increase).

Table V. shows that in the "ideal heating time" about two-thirds of the final temperature is reached. In our case $\frac{2}{3} \times 58 = 37$deg. C. Then from Curve B it will be seen

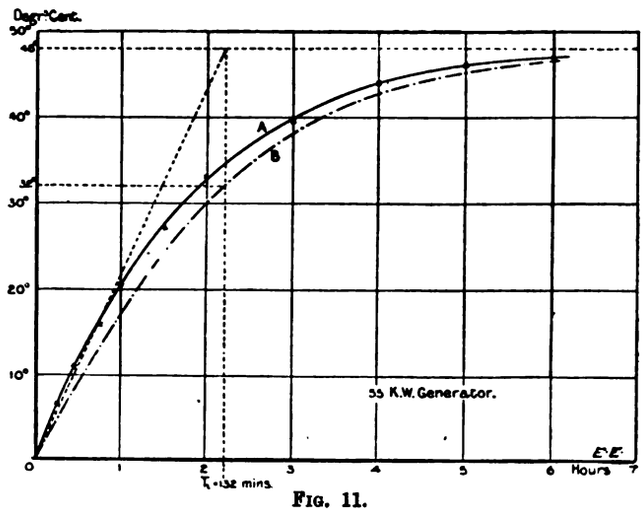

FIG. 11.

that this temperature is reached in 2 hours 12 minutes = 132 minutes—thus:

$$T_i = 132 \text{ minutes},$$

the initial rise is $\frac{58\text{deg. C.}}{132} = 0{\cdot}44\text{deg. C. per minute.}$

A current density of 1·25 amperes per mm.² corresponds to an initial rise of 0·50deg. C. per minute (Table I.), or making allowance for the heating of the copper,

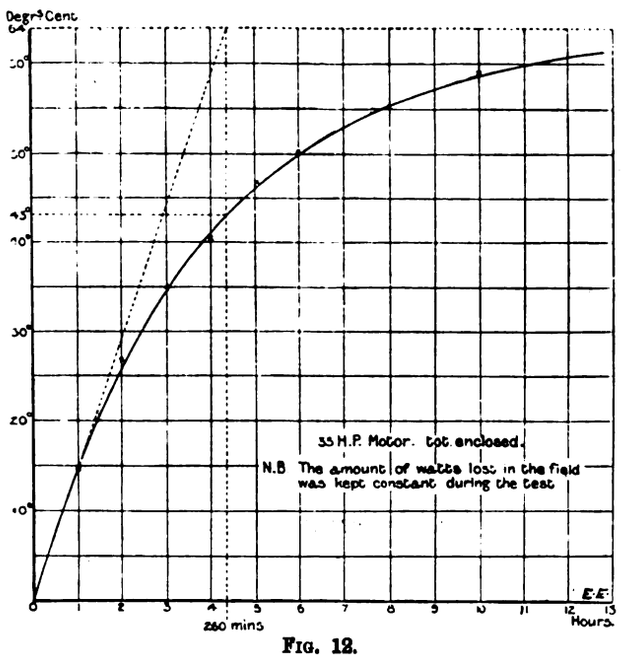

FIG. 12.

0·60deg. C. per minute. Therefore, the specific heat of the field coil owing to the influence of the insulation is $\frac{60}{44} = 1{\cdot}36$ times that of pure copper. The size of the wire was 0·088in.

*(To be continued.)*

## PERSONAL.

The Croydon Borough Council have appointed Mr. D. A. Mason to the position of electrical superintendent of the electricity works.

Mr. A. K. Taylor, well known in Hereford as an electrical expert, has been appointed electrical inspector at Bengal.

The Rotherham County Borough Council have appointed the borough electrical engineer, Mr. Edward Cross, to the position of borough electrical engineer and general manager of the tramways department with the combined salary of £350 per annum.

The Salford Tramways Committee have decided to recommend the Council to appoint Mr. George W. Holford, chief assistant in the new tramways department, as manager of the Salford system. The committee recommend that the commencing salary shall be £300 per annum, increasing annually by £50 to £500.

## BALLADS OF BUSINESS.

### No. 6.—Deserters.

Here's to the men who started
In the electric line,
From which they now are parted
By chance or fell design.
We know just why they left it:
Their reasons all agree,
From Brainandthew to N.D.U.,
"To get more £ s. d."

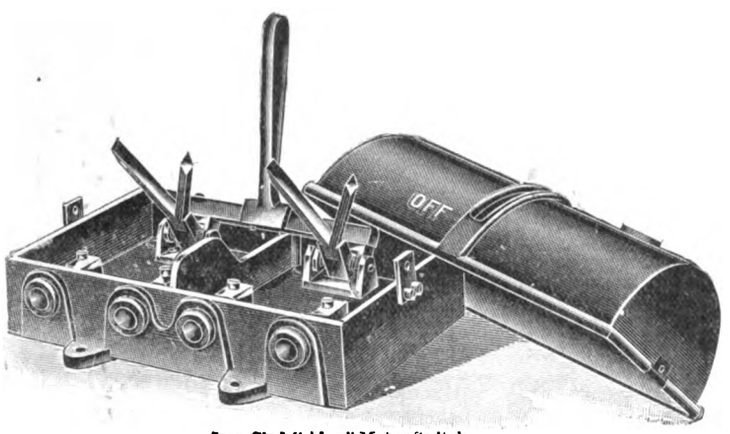
We'll drink success unto them
Whatever lines they're in—
Some are producing babies' foods,
And some dispensing gin;
Some upon 'Chance have started,
And some have gone o'ersea,
(While some bewail their lot in jail)
All for more £ s. d.

And shall we, proud survivors,
Scorn all who've left the race?
Ah! no; for some were strivers,
Discretion's no disgrace.
And—ask your conscience truly,
You of the I.E.E.—
If you'd their chance, would you not prance
To higher £ s. d.? B. C. H. J.

## TRADE NOTICES AND NOVELTIES.

### Ajax Motor Switches.

Messrs. Parmiter, Hope, and Co., Hulme Electrical Works, Manchester, have sent us one of their new iron-clad Ajax motor switches, which, we are told, have been designed to meet the demand for a thoroughly reliable motor switch at a low price. We have examined this switch as requested and find it combines several good features. For example, it has a very quick positive break, and it is quite impossible to leave it, even for a moment, in any position between full on and full off. The contact brush is made of phosphor bronze, and a thorough contact is ensured without "dragging." We understand the switch can be supplied with fuse in the same case, but this arrangement is not recommended for use on circuits above 250 volts. The accompanying illustration shows its general construction.



Iron-Clad "Ajax" Motor Switch.

### Large Alternators.

An illustration will be found among the advertisements in this issue of a very large armature, being part of one of the alternators which the Electric Construction Company, Limited, of London and Wolverhampton, have on order for the London County Council. For a long time past, when anything out of the ordinary run of electrical machinery has been required, we have been accustomed to see buyers placing their orders either in America or on the Continent, and the London County Council are to be congratulated on allowing a purely British firm to show how unnecessary, so far as large dynamos are concerned, it has been for public corporations and others to send their orders to foreign markets. The plant in question is amongst the largest, if not the largest, that has yet been called for. In all the E.C.C. are making four of these three-phase generators, each designed to give a continuous output of 3,200 kilovolt-amperes, at a speed of 94 revolutions per minute, and periodicity of 25 complete cycles per second per phase. The output of 3,200 kilovolt-amperes is to be rated with a power factor of 94 per cent. The working pressure is 6,600 volts, and the current per phase 280 amperes. The machines will be called upon to give an overload for two hours continuously of 20 per cent. additional current—that is, 350 amperes per phase. The field-magnet system is constructed directly upon the rim of the engine flywheel, in which the amount of stored energy, when revolving at normal speed, is 11,000 foot-tons. The E.C.C. are constructing the complete flywheel.

### "Pull" Type Button Switch.

We illustrate herewith a useful "Pull" type button switch which has been placed on the market by the Edison and Swan United Electric Light Company, Limited, Queen-street, London, E.C. This switch, it will be seen, is provided with an adaptor which presses the button when the cord is pulled, the on and off positions being actuated by one cord only. It is especially suitable for offices, warehouses, etc., and saves cost in the installation.

"Pull" Type Button Switch.

### Catalogues.

Insulating Materials, Driving Belts, etc.—Messrs. Arthur Cort and Co., 277, Camberwell New-road, London, S.E., have sent us a copy of their wholesale price-list of insulating hard or flexible vulcanised fibre, balata, guttapercha, and cotton belts, etc. A sample of red vulcanised fibre submitted to the Westminster Electrical Testing Laboratories was tested, with the results that a thickness of 0·625in. broke down with 16,100 volts alternating current, a thickness of 0·405in. broke down with 13,000 volts, and 0·220in. with 7,900 volts. The substance was tested between two plates, each of four square inches area, and the temperature of the surrounding air was 71deg. F. The material was not specially dried, but tested as received. The material is supplied in various colours and forms for different electrical and mechanical purposes. It is claimed that the balata, guttapercha, and cotton belts listed are conspicuous for their great strength, strong gripping and driving power, and almost entire absence of stretching.

Switchgears.—Messrs. Lionel Robinson and Co., Limited, Ferry Works, Thames Ditton, Surrey, makers of switches, fuses, cut-outs, regulators, and switchboards of standard patterns up to 11,000 volts, have issued a price list which includes illustrations and particulars of some useful specialities. Among them we note oil switches and fuses, automatic circuit breakers, and watertight motor-switchboards.

Automatic Fire Protection.—The descriptive booklet issued by the May-Oatway Fire Appliances, Limited, 92 and 94, Paul-street, Finsbury, London, E.C., for the current year partakes of the nature of an art production rather than of a catalogue, so excellent are the illustrations which it contains. In the front portion, Mr. G. H. Oatway, M.I.E.E., deals with fire-alarm practice, and describes the May-Oatway system of automatic alarms. Then follow illustrations of some notable factories, public buildings, etc., at home and abroad, in which the above system has been installed, and a long list of further installations. Although great progress has undoubtedly been made, it is complained that there is still no end of prejudice to overcome. The average insurance expert still advises for the protection of schools, dwellings, etc., the provision of so many buckets to a given floor space, and omits to make the slightest arrangement for calling sleepers in time to use them.

Moy Specialities.—A catalogue and three separate sheets recently issued by Messrs. Ernest F. Moy, Limited, Greenland-place, Camden Town, London, N.W., deal respectively with Mordey's patent fuses, ironclad motor-starters, double-pole knife switches in cast-iron cases, and distributing boards fitted with Acme switches.

## LOW-TENSION THERMAL CUT-OUTS.

BY ALFRED SCHWARTZ AND W. H. N. JAMES.

This paper, read before the Manchester Section of the Institution of Electrical Engineers on the 14th inst., contains the results of long-extended experiments carried out by the authors. We regret that we can only give a brief *résumé* of the same, but their conclusions are so clearly drawn up that they will be of great service to electrical engineers.

In the first instance, the paper points out that the thermal cut-out or fuse is essentially a protective device, its function being to guard the circuits and apparatus connected therewith from injury due to abnormally large currents. An excess current in a circuit may occasion injury in two ways, by setting up (1) excessive heating; (2) mechanical or electrical strains and effects, either in the conductors themselves or in the apparatus connected to them. In the first case the time duration of the excessive current directly affects the resulting injury, whereas in the second case the damage done may be practically instantaneous. All electrical apparatus should be capable of carrying continuously its normal current without injury, and also of carrying currents very considerably in excess of this for short intervals of time. The requirements for an efficient protective device would therefore seem to be: (1) safe operation with a definite excess current within a given time, at the voltage of the circuit on which it is employed; (2) efficient operation with currents largely in excess of that required to bring it into action; (3) suppression of the arc consequent on rupture without explosion or damage to neighbouring parts or connections; (4) reliability of action; (5) ease of replacement and inspection; (6) non-interchangeability of devices of different ranges; (7) simplicity of construction; (8) low first cost, and cheap renewal of wire.

A brief *résumé* is then given of the developments of fuses, from the early days when they were a source of fire risk due to the fuse wire being embedded in wood. As regards fuse wire, it is shown that the current required to fuse a wire of circular cross-section of given material is dependent upon the following variables: (1) diameter; (2) time of current of flow; (3) length of fuse wire employed; (4) environment and position of fuse; (5) previous history of fuse wire. These individual points are then investigated by the authors, who give the results of a large series of experiments in curve form. They investigate the agreement between the results so obtained and the well-known formula of Sir W. H. Preece: $C = 2{,}887\ d^{1.5}$.

Other curves are then given for the variation of the fusing current, with the diameter of the wire for aluminium, silver, aluminium with spring attachment, and tin. The results are reduced to formulæ which fit the curves obtained. These formulæ are all of the form $C = A\ d^n$. The constants for these formulæ with various wires are given in the accompanying Table A. These cover not only the particulars already mentioned, but also the effect of position and of the size of the terminals to which the wire is joined. The fusing current for copper strip and lead strip was also investigated by the authors, as was also the differences produced by the enclosure of fuses within tubes. Another important investigation was the effect of mechanical injury on the behaviour of fuse wire and the deterioration with time. Investigations on this latter point show that when copper wire is used and allowed to get red hot, oxidation rapidly proceeds. The point corresponding to red heat is somewhere about 75 per cent. of the normal fusing current of the material. The behaviour of fuses on short-circuit is discussed, and experiments again explained by the aid of curves. The last part of this valuable paper deals with the construction of fuses, and here again the information given is most useful, as is that on the best way of testing fuses.

The conclusions at the end of the paper read as follows: It has been shown that a fuse wire may be subject to a number of influences which affect its fusing current to a greater or less extent. Most of these disturbing effects are small, ranging from about 3 to 12 per cent., and it may be urged that with a device which becomes operative with excess currents of 100 per cent., errors of the order named may be safely neglected. If these sources of error were present singly this might be so, but this is rarely the case, and it is to the accumulated effect of several of them operating together that the so-called unreliability of fuses is due. The maximum errors due to various causes in open and semi-enclosed types of fuses are scheduled below.

TABLE A.—Table of Constants for use with the Authors' Formula, $C = A\ d^n$, for determining the fusing current of wires under various conditions, and for diameters measured in inches, centimetres, or millimetres, together with the nearest sizes on the Standard Wire Gauge. Wire free in air from terminal to terminal in all cases.

| Particulars of fuse. | Range on S.W.G. | Range of fusing currents. | Index. | Constant. Cm. | Constant. In. | Constant. Mm. |
|---|---|---|---|---|---|---|
| Tinned copper—lengths of 2in. and upwards, horizontal | 47 to 33 | 1 to 10 | 1·195 | 821·3 | 2,501 | 52·4 |
| Lengths of 6in. and upwards, horizontal | 33 to 18 | 10 to 100 | 1·403 | 1,768 | 6,537 | 69·9 |
| Lengths of 2in. and upwards, vertical | 47 to 33 | 1 to 10 | 1·195 | 775 | 2,360 | 49·4 |
| Lengths of 6in. and upwards, vertical | 33 to 18 | 10 to 100 | 1·403 | 1,680 | 6,220 | 66 6 |
| Length of 4in., horizontal, with large terminals | 33 to 18 | 10 to 100 | 1·586 | 2,980 | 13,100 | 77 5 |
| Ditto, vertical | 33 to 18 | 10 to 100 | 1·586 | 2,844 | 12,470 | 73·8 |
| Length of 1½in., horizontal, with small terminals | 47 to 33 | 1 to 10 | 1·264 | 1,178 | 3,828 | 64·1 |
| Ditto, vertical | 47 to 33 | 1 to 10 | 1·264 | 1,112 | 3 611 | 60·5 |
| Ditto, large terminals | 47 to 33 | 1 to 10 | 1·34 | 1,690 | 5,890 | 77·3 |
| Length of 1in., horizontal, with small terminals | 47 to 33 | 1 to 10 | 1·32 | 1,567 | 5,360 | 75 |
| Ditto, vertical | 47 to 33 | 1 to 10 | 1·32 | 1,480 | 5,060 | 70·8 |
| Length of 4in., vertical, in Manchester Corporation house service box, with cover of mass of terminals, about 100 grm. | 33 to 18 | 10 to 100 | 1·614 | 3,228 | 14,530 | 78·5 |
| Tin—lengths of 3in and upwards, horizontal | 43 to 20 | 1 to 10 | 1·131 | 146·6 | 420 6 | 10 84 |
| Ditto, lengths of 6in. and upwards, horizontal | 20 to 7 | 10 to 80 | 1·32 | 239·3 | 819 | 11·46 |
| Silver—lengths of 5in. and upwards, horizontal | 35 to 18 | 7 to 70 | 1·287 | 967 | 3,210 | 50 |
| Aluminium—length of 4in. and upwards, horizontal | 42 to 22 | 3 to 45 | 1·461 | 2,188 | 8,539 | 75·7 |
| Ditto for critical currents, with spring attachment | 42 to 20 | 2 to 30 | 1·271 | 640 | 2,091 | 34·3 |

*Preece's Formula: Redetermined Values.*—Tinned copper wires at 100 amperes, 19 per cent. high; at 20 amperes, correct; at three amperes, 20 per cent. low. Vertical as against horizontal position: tinned copper, 5 per cent.

*Effect of Length and Cooling due to Large Terminals.*—Percentage increase over fusing current for a length which is independent of cooling of terminals.

| Tinned copper. | Lengths 6in. | 5in. | 4in. | 3in. | 2in. | 1in. |
|---|---|---|---|---|---|---|
| For 115 amperes | 2 5% | 6·5% | 15% | 31% | — | — |
| For 10 amperes | — | — | — | 2% | 5% | 30% |

*Effect of Terminals.*—Increase in fusing current for heavy terminals as against light ones for tinned copper: for 115 amperes length 4½in., 6 per cent.; for 10 amperes length 2½in., 3 per cent.; for 10 amperes length 1½in., 5 per cent. Vibration: tin and lead, decrease in fusing current, 3 per cent. Enclosure in tubes: decrease in fusing current, 12 per cent.

*Contact with Porcelain.*—Tinned copper in semi-enclosed porcelain fuse-holder: (1) Wire arranged so as not to touch the porcelain, increase above normal fusing current = 2 per cent. (2) When pulled tight and close to porcelain F C increased 10 per cent.; lead wire arranged as above in (1) increase in F C = 18 per cent.; arranged as in (2) above, increase = 52 per cent. Tinned copper in holder of damper type: wire out of contact with porcelain, F C increased 5 per cent.; wire in contact with porcelain, but without damper, F C increased 14 per cent.; wire in contact with porcelain and damper, F C increased 24 per cent.

The fuse is an extremely simple device, and it is perhaps

Digitized by Google

due to this fact that it has not been treated with the necessary care. All experiments with fuses should be carried out with the greatest care if accurate results are to be obtained, and the same care should be exercised in their design and installation.

### Discussion.

Mr. C. D. Taite, from the chair, opened the discussion with deserving compliments to the authors, and mentioned that, among other things, the skin effect on lead and tin fuses was not generally known. The fact that Sir William Preece's well-known formula was proved to be in error by 10 per cent. evidenced the need for the paper. There were a great many forms of fuses on the British market, and in this our country differed from some foreign parts where there were fewer manufacturing firms, and consequently a fewer number of and more standardised patterns. He deprecated the idea of doing away with the old-fashioned fuse wire clamping screws, as upon emergency he believed that this design was very useful. He instanced a personal experience at an evening party, when, owing to the lights going out through the main fuse blowing, considerable inconvenience was caused, but the matter was readily rectified by himself with the aid of a mousetrap.

Mr. L. Andrews referred to the reputation for unreliability that fuses possessed, and instanced an occurrence at Hastings, when, with two fuses practically in series, one rated at 250 amperes and the other at 70 amperes, the *heavier* fuse blew upon a short occurring at a transformer on the far side of the lighter fuse. He could only account for this left-handed miracle on the assumption that the 250-ampere fuse had been heated up by an overload of long duration upon a branch circuit of 30 amperes, which was fed through this 250-ampere fuse, and that porcelain fittings had conducted the heat away from the 70-ampere fuse during the normal working of the transformer. He considered that it was practically impossible to fuse arc lamps, as a fuse that will not blow with the large excess currents due to starting up, etc., is too heavy when the normal current is increased in a less degree for long periods. He was greatly surprised at the result of the mechanical injury tests, which showed that a fuse cut in half almost was practically unaffected. The fact that there is more trouble with alternating-current than continuous-current fuses was, in his opinion, not due to a deterioration of the wire, but was the result of vibration at contacts, which were thereby loosened, and arcing was set up. It was very difficult to devise apparatus to overcome this—even locknuts were not wholly satisfactory in his own experience. He agreed with Mr. Taite as to the convenience of the old-fashioned fuse clamp arrangement, and instanced a case of lights jumping in church, which he found to be due to loose locknuts, and this matter was put right by him with the aid of the church door key as a main fuse. He advised reference to B. Hopkinson's paper to the Institution of Civil Engineers for some interesting details concerning carbon break, cut-outs, and magnetic blow-out apparatus.

Dr. C. C. Garrard thought that designers of low-tension fuses would find nearly all the data they require in the paper, which would have been additionally useful if the experiments had been extended to fuses of larger current-carrying capacity. With currents of 200 amperes and upwards the chief difficulty is the watt consumption and heating, as with a fuse of smaller size about 50 watts is the maximum allowable liberation of heat, and with a larger watt consumption the neighbourhood of the fuse gets excessively hot. With the object of standardising fuses he had been plotting curves of watt consumption and current during the last three years, and he thought that his method of testing corresponded more to working conditions than that advocated in the paper, as it was based upon the principle that any current below the melting-point value could be kept flowing through the fuse for an indefinite period without the fuse breaking circuit. He thought that it was useless to rate a fuse at 500 amperes if it would melt with 400 amperes passing for a couple of hours, and this result might be obtained by the methods mentioned in the paper. He instanced some remarkable results of increase of potential on breaking circuit upon fuses when a 10,000-volt increase was, in one instance, obtained on a very inductive circuit of 90 amperes at 220 volts continuous current. These rises were not only measured by a spark gap, but were confirmed as to their destructiveness by interposing pieces of paper between the electrodes, which paper was pierced by the spark made on breaking the fuse. Such a fuse would, therefore, cause damage to the apparatus that it was intended to protect, should it be needed to open the circuit.

Mr. E. W. Cowan commented on the singularity of a paper written by a professor being of such value to engineers! Terminal capacity he considered a great factor in determining the capacity of a fuse. From his experience, a fuse was useless in protecting an armature from a heavy reverse current from a battery. The principle of shunt fusing was insufficiently considered, as to the advantage of taking no current when working, but making the final break in a safe place. He hoped to have some details as to deterioration, as manufacturers were made, by consulting engineers, to run at 50 per cent. overloads. Circuit breakers for heavy currents were preferable to fuses, as the former opened at once on dead shorts, and used a time-element lag for less deadly effects. He also preferred long-drawn-out breaks to rapid snaps, which induced rise of pressure, among other things.

Mr. A. C. Cormack considered that atmospheric temperature would influence a fuse, and that a multiplicity of small fuses was better than a single large fuse. Terminal effects have got fuses their bad name for unreliability. Although automatic cut-outs were better for some purposes, like all automatic boxes of tricks, they were likely to go wrong, and where these existed a fuse should also be in series.

Mr. H. G. Baggs was grateful for the new formula evolved from the tests, although he thought Sir Wm. Preece's time-honoured $C = A\,d^{\frac{3}{2}}$ still good enough for workshop experimen's. He thought the time was coming when circuit breakers would take the place of fuses. He recommended that when the paper is published in the *Proceedings*, the paragraph as to RUNNING FUSES AT A MAXIMUM OF 50 PER CENT. OF THEIR NORMAL FUSING CURRENT should be printed in Roman capitals. The non-interchangeability of fuses was not desirable from a manufacturer's point of view, as circuits were sometimes used for different ratings as time went on.

Mr. C. C. Atchison appreciated the results of the experiments, as he had tried to make similar ones himself, but found that too much time was required. He considered that every type of house fuse box on the market had its defects, and corporations consequently had to make their own designs. The reference to changing fuses every three months was hardly based upon a consideration of work-a-day conditions, say, in an ordinary town with 2,000 fuses. As to the ousting of fuses by automatic contrivances: he believed that when fuses were standardised properly, the cut-outs would not be used at all. He preferred teak instead of porcelain for fuse boxes, and used this material charred on the inside to prevent combustion. Enclosed fuses were certainly very noiseless and sparkless in operation, and he instanced a case of one blowing in his station close to him, and only being found out by its effect on the machines.

Dr. Schwartz, in reply, referred to the mysterious efficiency of the damaged fuses, his only explanation being that the heat was conducted rapidly away by the remainder of the fuse wire. The alternating-current effect on fuse wire he considered was better explained by Mr. Andrews's theory of vibration than by Sir D. Salomons's idea as to molecular effects. He did not advocate putting fuses in oil, and preferred enclosing them in porcelain for special situations, as collieries, etc. He agreed that no fuse could be produced to save machines from sudden current rushes. The atmospheric temperature effect he considered to be inappreciable. He still preferred that fuses should be made non-interchangeable to any but authorised persons, and to these it would be simple to alter the standard fixed fittings in the fuse box by the substitution of other standard fittings of greater or less capacity. He disagreed with Mr. Atchison as to the perpetual unreliability of fuses. He thought that the Germans were steadily standardising fuses among other things. In that official-ridden country no ordinary man may replace a fuse, but he must employ the organised facilities to do such work. This was a nuisance to the householder, but it ensured reliability. A constant environment (such as with an enclosed dust fuse) adds to the constancy and reliability of the fuse, and he believed that this class would come more and more to the front. The only trouble was that they were not easy to refill, and the maker charges 8d. each, but his analyses of the filling materials used might help to save this.

## GLASGOW LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The monthly meeting of the above section of the Institution of Electrical Engineers was held on the 14th inst. at 207, Bath-street, Glasgow, Mr. Robert Robertson being in the chair. The evening was taken up with the discussion of the paper on "Earthing" by Mr. Lackie. A considerable number of lengthy written communications were received, and an exceptionally large number of those present took part. Many of the speakers, however, did not confine themselves to the subject matter of the paper.

Mr. James Johnstone (Glasgow), in a communication, said that while he agreed with the author's suggestion, that all metal sheathings of conductors should be kept clear of other metal work, the difficulty would be in getting this suggestion carried out. With regard to the author's suggestion of a resistance in the earth circuit, though it was decidedly novel, it still

Digitized by Google

left the whole question open to debate, because they could have no guarantee that plumbers, gasfitters, or bellhangers might not come along and earth the whole system from the earth circuit with its resistance. Of course, it was possible to test each separate installation to see that this had not happened, but who was to be at the expense of making such periodic tests? In the case of motors the adoption of a resistance in the earth wire would obviate a considerable amount of damage, and the risk of damage from gas or other metal pipes would be minimised if the motor earth resistance were inserted between the motor and the piping. Care would be required, however, to see that in works the earth-wire was taken beyond any adjacent water-meter.

Mr. ALLAN ARTHUR (Glasgow), in a communication, said that one disadvantage of having only one earth in a large building was that in the event of the earth-wire being broken the whole system was insulated from earth, or only connected to earth by accident. Another disadvantage was that if the earthing were in the basement, and a fault occurred on the top flat, all the tubing to the earth was momentarily alive, whereas if there was an earth on every flat only a small portion of the current would travel along the tube, while most of it would go right to earth on the top flat. Mr. Arthur had noticed that in the samples of bad wiring shown by Mr. Lackie slip tubing had always been used, without the necessary precautions being taken to bond across the different lengths of tube. He thought that lead-covered wiring properly installed made a very satisfactory job. He could not agree that insulating the sheathing and earthing at one point through a resistance would in no way interfere with the precaution for the safety of the public from shock, as a partial fault would blow the fuse, which it might not do if the extra resistance were inserted.

Mr. D. M. WATERHOUSE (London) sent a communication, in the course of which he said that he was unable to agree that it was just as necessary that conduits should be earthed where the pressure of supply was only 100 volts, as in cases where it was 250. He believed that the sectional area of the earth conductor should be in proportion to the fuse protection of the largest conductor in the conduit which is earthed by it. He thought that Mr. Lackie's figures with regard to electric fires showed the fallacy of the prevailing idea that continuity and earthing of itself afforded security against fire risk. He contended that to increase the resistance of the intentional earth would result in sending a larger current through any existing unintentional earth. It was not possible to completely insulate the whole run of conduits throughout a building except at considerable expense, however admirable the idea in itself might be. Either two independent earths ought to be made, or the earth-wire itself must be protected from mechanical injury by enclosure in a metal tube. He was strongly in favour of earthing lampholders on installations where continuity and earthing were arranged for at all other parts.

Mr. J. W. BLACK (Glasgow), in a communication, said that he thought it would be found that earthed cast-iron boxes had been used in nearly every case where the main fuse had gone with an earth on a three-ampere circuit. If well-designed fuse boxes with insulated or non-metallic cases were used, he thought it would be practically impossible for an earth on a three-ampere branch to do more than blow the three-ampere fuse. He was of opinion that if the metallic sheathing were made electrically continuous throughout, and earthed at one or more points, and the fuse boxes properly designed, there would be no need to resort to Mr. Lackie's main suggestion, which would be bound to add greatly to the cost if it were to be properly carried out. The ideal system, he thought, was some well-designed concentric system with return. Lampholders he considered the weakest part of the insulation, owing to the fact that manufacturers had kept to the standard sizes of the 100-volt days, and with this size it was impossible to get in the proper amount of space for 250 volts.

Mr. GEORGE STEVENSON (Glasgow) said he had no objection to offer to Mr. Lackie's three suggestions as regards lighting if the wiring were carried out with steel-armoured cables, which if insulated with a thin layer of tarred jute made, in his opinion, a better job than any of the conduit systems at present so fashionable. With power circuits, however, over and above the resistance, it would be necessary where motors were mounted direct on a metal framework making a good earth, to insulate the motor frame from the base-plate. This meant insulating brushes and washers for the holding-down bolts, and fibre or wood strips, which increased the cost and made the job less satisfactory from an engineer's point of view.

Dr. BOTTOMLEY (Glasgow) sent a short communication in which he said he substantially agreed with the suggestions made in the paper.

Mr. J. M. MUNRO (Glasgow) said the whole paper showed that they had not arrived at an ideal system of wiring. With all its disadvantages, he was inclined to hark back to wood casing. With regard to the fires mentioned by Mr. Lackie, he thought that the number was very small, considering the number of installations and the variety of work represented. Mr. Lackie's first suggestion would be difficult to carry out, especially in old buildings. He believed that architects were very much to blame in the matter. They made no real provision for artificial lighting. Perhaps they (the contractors) ought to blame themselves to some extent. They ought to consider what recommendations they could make, and then try to come to some agreement with the Institute of Architects. He had always endeavoured to get all tubes insulated from other metallic work in buildings, and while this had often added a little to the cost, he did not see that it presented any real practical difficulty in most cases. A proper external insulating cover to the tube was of great assistance, but it was difficult to get a cover which possessed all the necessary qualifications. He would be glad if Mr. Lackie would say how often in an average week the earth-fuse blew in the station.

Mr. F. A. NEWINGTON (Edinburgh) said that the author's references to electric fires were particularly interesting. If the public got the idea that electricity was unsafe, it would greatly hamper the industry. They were all agreed that electric lighting was the safest form of illumination, and it rested with them to do what they could on the lines laid down in the paper to keep the industry from getting a bad name. Although there was a temptation for contractors to do cheap work, he thought that in the long run good work would pay best. He did not see any good in insulating the earth connection. He would like to have further particulars about the seven fires which had been mentioned by the author as having occurred in installations where the metal piping was earthed. He believed it was not possible to keep the tubing carrying electric conductors clear of all other metal work. Even if it was done at first, the first plumber that came along might run his pipes across the electric tubing, and then the condition of affairs would be as bad as ever. If the piping were clear of all other metal work, of course a resistance in the earth circuit would be very suitable in reducing the flow of electricity, but with other metal work in contact it would only make matters worse. He believed that with the present methods of working it would be better and safer to earth to all the other metal work in the building. He hoped that Mr. Lackie's paper would enable them to arrive at some better method of doing installation work than they had at present.

Mr. H. A. MAVOR (Glasgow) said he entirely disagreed with Mr. Lackie's three main conclusions. He would insist upon earthing at as many points as possible. With regard to the second suggestion in the paper, it would be magnificent if it were possible, but seeing that it depended on the possibility of the first suggestion, which had been shown to be practically impossible, it was not of much use.

Mr. WM. MCWHIRTER (Glasgow) said it was high time new rules were laid down by the master of works, whereby no soft metal tubing would be allowed inside of buildings under any conditions whatever. He was also of opinion that all tubing used in connection with electric wiring should be screwed. He did not believe in bonding, because by the time tubing was properly bonded it was dearer than screwed tubing. He was afraid that the use of a resistance in such a way as Mr. Lackie had suggested would give rise to fire risks in addition to those which already existed. He disagreed with Mr. Lackie's theory that faults in lead-covered cables were often due to a strand breaking, piercing the rubber and earthing in the lead. Most of such faults, he considered, were due to electrolysis.

Mr. W. A. CHAMEN (Glasgow) said he quite realised the danger and the objections that might arise against putting a resistance into the earth circuit, but after all they must be guided by their long years of experience, and they had come to find that the theories they had propounded and proved to their own and other people's satisfaction did not always work in practice. There was no doubt that their older theories about dead earths might still be right. They seldom got a dead earth, however, and that was how they found it necessary to insulate the earth-wire. They insulated the earth-wire because it sometimes did not make earth, and then it was a source of danger if it was near a gas-pipe. The real difficulty which they had with the earthing of the metal sheath was the momentary rush of current. That was the point that none of them realised sufficiently. Mr. Lackie had made a determined attempt at a compromise, and he thought it would be wise to give the arrangement he proposed a trial. Although it might seem impossible to keep tubing clear of all other metal work, he though it would be well that they should set that up as a rule to be adhered to as far as possible, and very probably they would be able to achieve it in a great many cases. If on testing they found that they had not managed to keep the tubing isolated throughout, then it would be wise to put in the necessary resistance. There was no reason why Mr. Lackie's suggestion should not be tried, and if they did not succeed in keeping the tubing clear they could give the resistance in the earth leads a trial.

A number of other speakers took part in the discussion, among them Mr. MORDEY (London), Mr. PILKINGTON (Glasgow), and Mr. MACKENZIE (Glasgow). Owing to the lateness of the hour it was agreed to postpone the hearing of Mr. Lackie's reply.

## FORTHCOMING EVENTS

FRIDAY, MARCH 24.

**Physical Society.**—At 5 p.m., at University College "Note on the Voltage Ratios of an Inverted Rotary Converter," by Mr. W. C. Clinton; "On the Flux of Light from the Electric Arc with Varying Power Supply" by Mr. G. B. Dyke; "The Application of the Cymometer and the Determination of the Coefficient of Coupling of Oscillation Transformers," by Prof. J. A. Fleming, F.R.S.; exhibition of cymometers and other instruments.

**Institution of Civil Engineers.**—At 8 p.m., students' meeting. "The Wanki to Victoria Falls Section—Victoria Falls Railway," by Mr. C. T. Gardner; and "Design of a Double-Line Plate-Girder Railway Bridge," by Mr. H. S. Coppock.

**Royal Institution.**—At 9 p.m., "A Pertinacious Current," by Sir Oliver Lodge, F.R.S.

**Electro Harmonic Society.**—At 8 p.m., smoking concert in King's Hall.

SATURDAY, MARCH 25.

**Royal Institution.**—At 3 p.m., "Electrical Properties of Radioactive Substances," by Prof. J. J. Thomson, F.R.S. (Lecture III.).

**Institution of Electrical Engineers (Manchester Students' Section).**—Visit to Liverpool and Southport Electric Railway. Leave Victoria Station at 2.10 p.m.

**Paddington Electrical Exhibition.**—Opening.

MONDAY, MARCH 27.

**Society of Arts.**—At 8 p.m., "Telephony," by Mr. H. Laws Webb. (Lecture III.).

TUESDAY, MARCH 28.

**Royal Institution.**—At 5 p.m., "Vibration Problems in Engineering," by Prof. W. E. Dalby (Lecture II.).

**Institution of Electrical Engineers (Manchester Section).**—At 7.30 p.m., "Use of Electrical Energy in Mines and Collieries," by Mr. A. B. Mountain.

WEDNESDAY, MARCH 29.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m., "A Modern Generating Station, with special reference to the Lots-road, Chelsea, Station," by Mr. Chaffers.

FRIDAY, MARCH 31.

**Compatriots' Club.**—At 5.30 p.m., Westminster Palace Hotel, "The New German Commercial Treaties and their Probable Effect on British Industries," by Mr. W. A. S. Hewins.

**Institution of Mechanical Engineers.**—At 8 p.m., "First Report, Steam-Engine Research Committee," by Prof. D. S. Capper (further discussion).

SATURDAY, APRIL 1.

**Association of Municipal Corporations.**—Annual meeting at the Guildhall, when the agreement between the National Telephone Company and the Government and other subjects will be discussed.

---

**Rontgen Society.**—April 6, exhibition evening.

**Institution of Civil Engineers.**—The thirteenth "James Forrest" lecture will be delivered by Colonel R. E. C. Crompton, R.E. C.B., on Monday, April 10, at 8 p.m., the subject being "Unsolved Problems in Electrical Engineering."

# LEGAL INTELLIGENCE.

## DEFECTS IN ELECTRIC MAINS.

In the King's Bench Division Messrs. A. H. Midwood and Co., Manchester, sued the Lord Mayor and Corporation of Manchester to recover the estimated loss of the plaintiffs' stock-in-trade, which was destroyed by fire caused by the fusing of one of the Corporation's electrical cables. The plaintiffs alleged that the Corporation had laid their mains in such a way as to constitute a nuisance, and that the fire was caused by their negligence. The Corporation denied the allegations.

Counsel having outlined the case, it was agreed that the following points should be left to the jury:

1. Was the fire caused by the fusing of the Corporation's cable?
2. Does the system adopted by the defendants constitute a danger to persons having property adjacent to the mains?
3. Is the method of localising faults by the burning out or smoke tests a reasonable and proper method, having regard to the risk of fire?
4. When the defendants became aware of the fault, did they deal with it for the purpose of preventing fire in a reasonable and proper manner?

**Mr. A. L. Taylor, M.I.E.E.**, on behalf of the plaintiffs, said that the system of "linking-up" was neither usual nor advisable in a city like Manchester. It was reasonably practicable to carry out a system of electric lighting without danger to property. Liverpool had been running a system 10 years longer than Manchester, and their mains had been on fire, but there had not been a single case of fire spreading inside premises.

Other evidence having been given on behalf of the plaintiffs, **Mr. Fletcher Moulton**, on behalf of the defendants, said that everything prudence dictated had been done by the defendants.

**Mr. Pearse**, the city electrical engineer, stated that on the day in question an abnormal current was observed to be passing to earth through the middle wire at one o'clock, and proper steps were taken.

**Mr. Patchell, M.I.E.E.**, and **Mr. C. L. Sparks** said that the Manchester system complied with the Board of Trade regulations.

The case was decided yesterday afternoon in favour of the plaintiffs. This important decision reaches us too late for comment this week.

## WILLESDEN ELECTRIC LIGHTING.

In the Court of Appeal on Wednesday the appeal of the Metropolitan Electric Supply Company, Limited, against the judgment of Mr. Justice Farwell, in an action instituted by the Attorney-General at the instance of the Willesden Urban District Council, came on for hearing. The proceedings before the Court below were reported in our issue of Nov. 4, 1904. On that occasion the Attorney-General obtained a verdict restraining the company from supplying current for lighting to the Great Western Railway from the company's generating station at Willesden, on the ground that the company's powers only entitled them to generate energy at Willesden, and not to give supply within that area.

Their Lordships, without calling upon counsel for the respondents, came to the conclusion that there was an express proviso in the defendants' Act of Parliament prohibiting the supply of electrical energy outside the specified area, and dismissed the appeal, with costs.

## MELBOURNE TRAMWAY AND OMNIBUS COMPANY, LIMITED v. KIDNEY.—MELBOURNE TRAMWAY AND OMNIBUS COMPANY, LIMITED v. THE CORPORATION OF THE CITY OF MELBOURNE.

The House of Lords last week heard consolidated appeals from judgments of the Supreme Court of the State of Victoria of March 13, 1902, and Dec. 7, 1903.

The appellants are a limited company authorised by an Act passed in Victoria in 1883 to construct tramways and work and run carriages thereon within the city of Melbourne and elsewhere. The Corporation of Melbourne claimed the power, as the licensing authority, to make by-laws relating to carriage licenses in their city. The first decision appealed against a conviction of the company by the court of petty sessions for employing for hire a tramcar without having had a license granted in respect of it. The second judgment supported a by-law made by the Corporation relating to the licensing of the company's tramcars and employés. Both cases raised substantially the same question as to whether the company were obliged to take out and pay for licenses in respect of the tramcars and their drivers and conductors, the decision in both cases being adverse to the company.

Judgment reserved.

## "LIVE" WIRE ACCIDENT.

### Brough v. the Potteries Electric Traction Company, Limited.

This was an action to recover damages for personal injuries sustained through the alleged negligence of the defendant company.

The plaintiff was employed as a loader at a colliery. It appeared that about an hour previously to the plaintiff starting work one morning there had been a breakage of the wires connected with the overhead electric tramway, and one of the wires hung down upon the roadway. The plaintiff apparently did not observe the wire as he crossed the road, and it curled itself round his body. The plaintiff was terribly injured, and had been unable to follow his employment having lost the use of his left arm. The alleged negligence on the part of the company consisted in the fact that the bridle wire leading from the side standard to the central wires was called upon to bear more strain than it should if the wires were properly constructed. It was contended that the bridle and the span wire should have separate and independent attachments to the iron standard. The fact that the bridle wire was alive, although it hung without touching the trolley wires, was alleged to indicate defective insulation. It was also urged on behalf of the plaintiff that the company were negligent in not immediately sending to the scene of the accident.

Medical and expert evidence was given on plaintiff's behalf, the witnesses including Mr. C. E. C. Shawfield and Mr. H. M. Sayers while Mr. G. J. Conaty tendered evidence for the defendants, on behalf of whom it was contended that they had taken all reasonable precautions.

His Lordship held that where a "live" wire was found hanging down into the roadway the onus was upon the defendant.

The jury found for the plaintiff, and assessed the damages at £300.

## FOOTBOARD RISKS.

Judge Greenwell gave judgment at the local county court for the Newcastle Corporation in a case in which they were sued by a passenger for injuries received through being jerked off a tramcar. At the time plaintiff was standing on the footboard after it had passed the stopping-place, where, he alleged, he had told the conductor he wanted to alight. The defence was that he gave no order, and tried to alight as the car was moving. The judge said that while he accepted the plaintiff's statement, he did not see how that gave him a claim. If he had given an order with which the conductor did not comply, that did not justify him in remaining on the footboard after the car had increased in speed on passing the stopping-place. The footboard was a place where a passenger had no right to travel. It was common for people to travel on it, but he thought they must occupy the same position as people who tried to get off while the car was moving—they were there at their own risk.

# COMPANIES' MEETINGS AND REPORTS

## OLDHAM, ASHTON, AND HYDE ELECTRIC TRAMWAYS.

The ordinary general meeting of this Company was held last Friday, Mr. Emile Garcke presiding.

The **Chairman** have reviewed the report (a notice of which we gave last week), the same was adopted.

## CORK ELECTRIC TRAMS AND LIGHTING.

The annual meeting of this Company was held on Friday last, **Mr.** A. P. Monks presiding.

The **Chairman** stated that the receipts for the year were £45,148, and after the payment of expenses (£28,123) and the interest on debentures (£4,302), there remained £13,427. Of this sum £5,500 was paid in dividends on the preference shares, £1,000 carried to depreciation and insurance account, and it was proposed to pay 5 per cent. on the ordinary shares, carrying forward £885. The lighting and power business continued to show progress. The traffic receipts were also satisfactory.

The report was unanimously adopted.

## MERSEY RAILWAY.

The report of this Company for the half-year ended Dec. 31, 1904. states that the train mileage run during the half-year was 415,625 miles, as compared with 401,046 during the corresponding six months of 1903. The number of passengers conveyed during the half-year has been 4,657,876, as against 4,153,777 for the corresponding period of 1903, exclusive of season-ticket holders. The total receipts from all sources have been £41,789, as compared with £37,358 for the corresponding period of 1903. Working expenses, exclusive of the exceptional charges for pumping, ventilation, and lifts, have been £22,029, equal to 69·17 per cent., as against £28,203, equal to 75·50 for the corresponding six months. These exceptional charges for pumping, ventilation, and hydraulic lifts for the past half-year amounted to £3,854, equal to 9·22 per cent., as compared with £4,237, or at the rate of 11·34 per cent. for the corresponding period of 1903.

## SALISBURY ELECTRIC LIGHT AND SUPPLY.

The annual meeting of this Company was held last week, Mr. W. M. Hammick (chairman of the directors) presiding.

The report stated that the number of consumers had advanced from 662 with 23,833 lamps connected, to 820 with 26,674 lamps connected, thus showing a steady increase. The profit on the year's working, including £318. 0s. 4½d. brought forward from last account, amounted to £4,916. 3s. 7½d., and after paying an interim dividend at the rate of 4 per cent. for the half year, amounting to £600, and £1,452. 1s. 6d. interest on debentures and outstanding accounts, there remained a balance of £2,864. 2s. 1½d. to be dealt with. The directors recommend that a further dividend at the rate of 7 per cent. for the half-year be paid, making, with the interim dividend already paid, a total dividend at the rate of 5½ per cent. per annum for the whole year, and that £1,600 be placed to reserve, leaving £214. 2s. 1½d. to be carried forward to the next account.

The report was adopted.

## SLOUGH AND DATCHET ELECTRIC.

The report for the year ended Dec. 31 states that the capacity of the generating station is now 870 h.p., as compared with 510 h.p. last year, and the order has been given for an additional boiler of 500 h.p., which will be installed this year. The supply mains have been extended in many directions to connect up additional customers. The capital expended to the end of the year 1903 was £31,252. 9s. During last year a further sum of £7,729. 18s. 7d. was expended, bringing the total up to £38,982. 7s. 7d. The number of 8-c.p. lamps and motors connected up to Dec. 31, 1903, was 3,126. During the year 2,482 were added, bringing the total up to 5,608, of which 198 represent the motor power. The directors, after very careful consideration, decided early in the year to reduce the price of current to 6d. per unit for lighting and 3d. for motor power. The total revenue for the year was £3,011. 7s. 1d., including the sale of current in bulk to the Windsor Company, which amounted to £1,452. 5s. 2d. The total net profit available for distribution after adding the sum of £294. 17s. 9d. brought forward from the previous year is £1,628. 8s. 1d., and out of this the directors recommend the declaration of a dividend at the rate of 3 per cent. per annum (less income tax), which will absorb £1,050, leaving £578. 8s. 1d. to be carried forward.

## NEWMARKET ELECTRIC LIGHT.

The annual meeting of this Company was held at the offices, **Mr.** G. H. Verrall, J.P. (chairman of directors), presiding.

The directors' report stated that during the past year 1,737 8-c.p. lamps had been connected with the mains, making a total connected at the end of the year of 18,190 lamps. Applications for a further 728 lamps had been received this year. The profit on the year's working, added to £312. 18s. 10d., brought forward, amounted to £2,019. 5s. 8d., which, after providing for debenture interest, £707. 0s. 10d., left a balance of £1,312. 4s. 10d. The directors recommended that a dividend of 4½ per cent. be paid, that £250 be carried to reserve, and that £134. 10s. 6d. be carried forward.

The **Chairman**, in moving the adoption of the report and accounts, said that in addition to the applications mentioned in the report, nearly 300 more lights had been applied for, and 117 had been connected since the report was drawn up.

The report was adopted.

## BRITISH INSULATED AND HELSBY CABLES.

The report for the year ended Dec. 31, to be submitted at the meeting at Liverpool on the 27th inst., states that the profit for the year amounted to £129,817, to which has to be added the balance brought forward £6,165, making £135,982. The directors recommend a further dividend of 4 per cent. on the ordinary shares, making 8 per cent. for the year, carrying forward £7,114. The volume of trade has been large, but competition still continues very keen. A further sum of £8,500 has been added to the special reserve account. Additions to new plant and machinery, etc., during the year at the Prescot, Helsby, and Liverpool works have been necessitated in order to facilitate the Company's business, and widen the scope of its operations.

## HOVE ELECTRIC LIGHTING.

The annual meeting of this Company was held on the 16th inst., Colonel A. J. Filgate presiding. Particulars of the report appeared in our issue of the 10th inst.

The Chairman having revieved the position generally the report was adopted.

## COUNTY OF LONDON ELECTRIC SUPPLY.

The annual meeting was held at Winchester House on the 16th inst., Mr. J. P. Braithwaite presiding. In moving the adoption of the report (particulars of which appeared in our issue of the 10th inst.), the chairman alluded to the Company's Bill, now before Parliament, for extending their operations. The report was adopted.

## SOUTH WALES ELECTRICAL POWER.

The report of this Company shows that steady progress was made during the past year. Four stations—Bridgend, Cwmbran, Neath, and Pontypridd—have now been completed, and are supplying current receipts for the past year, amounting to £7,000, as compared with £1,900 for the previous 12 months. Arrangements have been made to supply a large number of collieries and works with current to the extent of 10,000 h.p., and the demand is stated by the directors to be continuously increasing. An important scheme of electrical development is foreshadowed in the county of Durham, the Newcastle Supply Company, which furnishes power to nearly all the Tyneside shipyards having agreed to purchase the shares in the County of Durham Electric Distribution undertaking, which holds provisional powers for Gateshead, Durham, Chester-le-Street, Jarrow, and South Shields.

## PERTH (AUSTRALIA) ELECTRIC TRAMWAYS.

The report for the year 1904 states that after paying the interest on the first and second debenture issues, the sinking fund for first debenture stock, and the trustees' fees, the balance standing to the credit of profit and loss account is £14,180, which is carried to profit allocation account. To this balance of profit of £14,180 is added the balance brought forward from last year—viz., £3 232 and £500 proportion of interest on guarantee deposit—making £17,912 from which has to be deducted £9,000 for preference dividends (paying all arrears to date) and £450 dividend tax in Western Australia. A balance is thus left of £8,462, of which £500 accrued interest as above is payable to the trustees for the debenture holders, leaving a balance of £7,952. Out of this sum the directors propose to add £5,000 to reserve account, leaving, with the £500 referred to above, a balance of £3,462 to be carried forward.

## BROMPTON AND KENSINGTON ELECTRICITY SUPPLY.

The annual meeting was held on the 16th inst., at Winchester House, London, Mr. H. R. Beeton presiding. Particulars of the report appeared in our last week's issue.

The **Chairman**, after remarking upon the need of legislation to relieve companies from burdensome and growing taxation, stated that the Board contemplated further reductions in price, believing that such a policy was best in the interests of the Company.

The report was adopted.

## OXFORD ELECTRIC.

The fourteenth annual meeting of this Company (particulars of whose report we gave last week) was held last Friday, under the presidency of the chairman, Sir Henry Mance.

The report was adopted.

# NEW COMPANIES REGISTERED.

**Simplex Motor Syndicate, Limited.**—Capital, £1,200. Object: to acquire from J. D. Roots certain patents and rights relating to improvements in internal-combustion engines, and to carry on the business of motor manufacturers, etc. Registered office: 83, Upper Thames-street, E.C.

**Hexham and District Electric Supply Company, Limited** — Capital, £30,000. Object: to supply electricity for light, heat, power, traction, and other purposes in the urban district of Hexham,

Digitized by Google

and the parishes of Acomb, Sandhoe, Hexham, West Quarter, and Warden, all in Northumberland; to acquire a transfer of the rights and powers granted to E. P. Harvey, of Richmond, Surrey, by the Hexham Electric Lighting Order, 1904, etc. Registered office: Bank-chambers, Hexham.

### Liens Registered.

**Eastern Telegraph Company, Limited, London, E.C.**—Lien registered March 10, for £10,000 debenture stock, ranking *pari passu* with previous issues amounting to the total of £1,887,704; charged on the undertaking and revenue of the company.

**Edison-Bell Consolidated Phonograph Company, Limited.**—A trust deed, dated Feb. 20, 1905, to secure £15,000 prior lien bonds has been registered. Property charged, certain patent and trade marks, the leasehold lands and hereditaments known as Newbery House, 39, Charing Cross-road, W.C., and the company's other assets, present and future, including uncalled capital. Trustees: Sir William H. Quale-Jone, Kt., 14, Royal-avenue, Chelsea, and E. Dexter, 11, Ironmonger-lane, E.C.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Manchester.**—The Corporation require tenders for switchboards. Tenders by April 4.

**Salford.**—The Corporation invite tenders for wiring their Seidley School. Tenders by 31st inst.

**Hornsey.**—The Town Council require tenders for cables, meters, junction boxes, etc. Tenders by March 27.

**Cartagena.**—The Public Works Department, Madrid, require tenders for electrification of the local tramways.

**Colchester.**—The Corporation require tenders for electric pumping plant and surface condensers. Tenders by April 5.

**Sofia.**—The District Finance Commissioners require 15,000 insulators, elements for batteries, etc. Tenders by April 3.

**Christiania.**—The Post and Telegraph Department require tenders for 8,000 kilos. of ¼mm. bronze wire. Tenders by April 10.

**St. Marylebone.**—The Borough Council invite tenders for the supply of house meters, including maintenance for two years. Tenders by April 4.

**Salford.**—The Corporation invite tenders for the wiring of the new Council school, Liverpool-street, Seedley. Tenders by March 31. See advertisement.

**Bucharest.**—The Post and Telegraph Department require tenders for 13,000 kilos 3mm. bronze wire and 120 kilos 1½mm. copper wire. Tenders by March 29.

**Bradford.**—The Corporation invite tenders for 2,500 kw. of motor-generators or rotary transformers. Tenders by March 30. Full particulars in our advertisement columns.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**French West Africa.**—The Governor-General of French West Africa, at Dakar, requires tenders for the erection and equipment of a central station at that place. Tenders by May 15.

**Bilbao.**—The Public Works Department at Madrid require tenders for the concession of an electric tramway in Bilbao, from the Calle de Hurtado de Amézaga to Plaza Circular. Tenders by April 24.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Utrecht.**—The Municipal Authorities require tenders for 20 electric motors for the tramways. Specifications may be obtained at 5s. from the Municipal Secretary, Town Hall, Utrecht. Tenders by 2 p.m. on April 8.

**Madrid.**—The Post and Telegraph Department (Direccion de Telegrafos y. Correos), Madrid, require tenders for 65,000 insulators. Tenders by March 28. A deposit of 5 per cent. of the tender value is required.

**Keighley.**—The Electricity Committee invite tenders for the following plant: (Contract No. 9) one Lancashire boiler; (10) one 300-kw. direct-current steam dynamo, high-speed enclosed engine. Tenders by 10 a.m. on March 27.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station. Specification No. 619 may be obtained from the Government Railways Office, Brussels.

**Stockport.**—The Gas and Electricity Committee invite tenders for supply and laying of electrical feeder cables. Specifications, etc., may be obtained from Mr. A. J. H. Carter, borough electrical engineer, Millgate, Stockport. Tenders by March 30.

**Glasgow.**—The Trustees of the Clyde Navigation invite tenders for electric power generating and lighting plant for Clydebank Dock. Specifications, etc., may be obtained from Mr. T. R. Mackenzie, 16, Robertson-street, Glasgow. Tenders by April 10.

**Rathmines (Ireland).**—The Rathmines and Rathgar Urban District Council invite tenders for condensing plant. Specification, etc., may be obtained from Mr. George F. Pilditch, A.M.I.E.E., Electricity Works, Rathmines. Tenders by March 27.

**Birmingham.**—The Tramways Committee invite tenders for supply, delivery, and erection of 200 electric tramway cars. Conditions, specifications, etc., can be obtained from Mr. Alfred Baker, general manager, 254A, Corporation-street, Birmingham. Tenders by April 4.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Littleborough (Lancs.).**—The Gas and Electricity Committee invite tenders for erection and completion of proposed transformer station, Butterworth-street, Featherstall-road. Particulars, etc., can be obtained from Mr. S. S. Platt, borough surveyor, Rochdale. Tenders by 12 noon on March 29.

**Hammersmith.**—The Council invite tenders for the supply of boiler flues and economisers; high pressure steam-pipes; high-pressure feed-water pipes; exhaust steam, feed-water heater, and circulating-water pipes; steam-valves and feed-water heaters; and coal elevator. Tenders by April 5. See advertisement.

**London, S.W.**—The London County Council invite tenders (a) for the manufacture, delivery, and erection of eight 500 kw. induction motor-generators for certain sub-stations in connection with the Council's electric tramways, and for the supply and delivery at the Greenwich electricity generating station of (b) general wiring material and (c) low-tension cables, cable boxes, etc. Particulars may be obtained at the County Hall. Tenders by 10 a.m. on April 4.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

## RESULTS OF TENDERS.

**Hull.**—The Corporation have accepted the tender of Messrs. Siemens Bros., of London, for mains.

**Grimsby.**—The Corporation have accepted the tender of Messrs. Crompton and Co., Limited, Arc Works, Chelmsford, for the supply of motors for the next two years.

**Fulham.**—The tender of the Universal Engineering Company, Limited, for the construction of the brick chimney shaft at the electricity works, at £2,157. 10s., has been recommended for acceptance.

**Aberdeen.**—The Gas and Electric Lighting Committee of the Town Council recommend the acceptance of the tender of D. Bruce Peebles and Co., Edinburgh, for a 420-kw. generator for the electrical department.

**Ilford.**—The Urban District Council have accepted the tender of Messrs. Pullen and Shore, 97, Deansgate, Bolton, at £1,000, for the installation of a telephone fire-alarm system on the double or metallic principle.

**Stockport.**—The Tramways Committee have accepted the tender of Messrs. J. and W. S. Briscoe, Longshut-lane, Stockport, amounting to £10,326. 12s. 5d., for the construction of the roadway in connection with the Hazel Grove tramways.

**Deptford.**—The Borough Council have accepted the tender of Messrs. F. and C. Osler, of Oxford-street, W., at £532. 14s., for the supply of electric light brackets, electroliers, and fittings in connection with the new municipal buildings in New Cross-road.

**Mirfield.**—The District Council have accepted the following tenders: Callender's Cable and Construction Company, cables, troughs, packing, etc., £312 4s. 2d.; British Thomson-Houston Company, meters, £112. 6s. 8d.; Westinghouse Electrical Engineering Company, transformers, £204. 17s.

**Stoke Newington.**—The tender of Heenan and Froude, Limited, for the erection of destructor buildings and plant, at a cost of £8,345, has been accepted. Other tenders were Horsfall Destructor Company, Limited, £5,669 (single plant only); Meldrum Bros., Limited, £8,964 (duplicate plant).

**Erith (Kent).**—The Urban District Council have received the following tenders for the execution of all work required under the Council's assisted wiring scheme for period ending March 31, 1906: J. T. Jarvis and Sons, Pier-road, Erith, 10s. 6d per point (accepted); W. Dickinson, Bexleyheath, 10s. 9d.; G. A. Moore, Bexley-road, Belvedere, 12s. 6d.; Woodville Electric Company, Brook-street, Belvedere, 12s. 10d.; Hooper, Kearey, and Co., Greenwich, 14s.; Ward Bros., 28A, Basinghall-street, E.C., 14s.

**Battersea.**—The Borough Council have accepted the tender of Messrs. Babcock and Wilcox, Limited, in connection with the extension plant now being provided at the central electric generating station, at £1,810. The following tenders were also accepted for annual supplies: Messrs. Charrington, Sells, Dale, and Co., coal; Sloan Electrical Company, carbons for arc, etc., lamps; Willcox and Co., oils and engine-room stores; Electrical Company, electricity meters; Callender's Cable and Construction Company, service joint-boxes, etc., and cables.

**Lowestoft.**—The Corporation have received the following tenders for one water-tube boiler with superheater, brickwork settings, and accessories, together with the necessary pipework:

| | | | |
|---|---|---|---|
| Babcock and Willcox, 30, Farringdon-street, E.C. (accepted) | £1,337 | 0 | 0 |
| Sterling Boiler Company, 35, Victoria-street, S.W. | 1,391 | 0 | 0 |
| E. Le Bas and Co., Dock House, Billiter-street, E.C. | 1,391 | 0 | 0 |
| B. R. Rowlands and Co., Climax Works, Reddish, near Stockport | 1,415 | 0 | 0 |
| E. Danks and Co., Oldbury, near Birmingham | 1,423 | 10 | 0 |
| Clarke, Chapman, and Co., Victoria Works, Gateshead-on-Tyne | 1,464 | 0 | 0 |

**Geneva Tramways Co.**—The receipts for February amounted to £6,225, being an increase of £414 over last year.

Digitized by Google

# BUSINESS NOTES.

## TRACTION.

**Newcastle.**—Two top-covered cars have made their appearance on the Corporation's system.

**Southport.**—The electrification of the pier tramway by the British Westinghouse Electric Manufacturing Company has been completed.

**Beckenham.**—The Urban District Council's proposal to introduce motor 'buses instead of electric trams has elicited a chorus of disapprobation in the local Press.

**Knutsford.**—The light railway scheme for Knutsford and Warrington came before the Light Railway Commissioners last week, when, owing to the quantity of opposition, it was withdrawn.

**District Railway.**—Mr. Yerkes on Monday received a deputation of the company's employés in reference to the scale of pay to come into force with the electric trains. No settlement was arrived at.

**Yarmouth.**—The work of electrifying the Gorleston section has been commenced. It is expected that this route, which is largely patronised by seaside visitors, will be ready by the early summer.

**Bradford.**—It is estimated by the local Press that the Corporation tramway receipts for the year ending 31st inst. will reach something like £230,000—roughly speaking, between £232,000 and £233,000 in excess of last year's takings.

**Dublin.**—It is reported that the tramway company had agreed to supply electric current for the public light of Blackrock, as a result of which that Council's opposition to the company's Bill now before Parliament may be withdrawn.

**Stockport.**—The contract for the electrification of the Hazel Grove line has been awarded, as will be seen in our "Results of Tenders" column. It is expected that the contractors will commence the work on March 27. A start will be made at both ends.

**Rochdale.**—The Corporation have some eight miles of new track to put down in the districts of Sudden, Marland, and Littleborough, which must be completed by August, as provided by the Corporation's Act. The work is being proceeded with vigorously.

**Ackworth.**—An enquiry has been held by the Light Railway Commissioners into the Ackworth and North Lindsey light railway scheme. The total mileage proposed is 53, and the cost is estimated at £580,000. Opposition was offered by the railway companies in the districts affected.

**London County Council.**—The receipts for the week ended the 11th inst. totalled £12,554 against £10,130 last year, and for the period from April 1 the aggregate was £625,232 against £485,490. The Council's Tramway Bill will come on for second reading in the House of Commons on April 6.

**Burton.**—The Town Council have instructed the electrical engineer to obtain tenders for a 100-kw. current dynamo, to be coupled to the shaft of No. 1 alternator, together with the switchboard and connections, at a cost of about £500, to meet the increased demand which the additional service of cars which the Burton and Ashby Light Railway will call for.

**Wellingborough Tramways Bill.**—At the quarterly meeting of the Northampton County Council it was stated that the Council's opposition to this Bill was simply intended to secure reasonable terms for the public, not to kill the measure. The Raunds Urban District Council have practically agreed terms with the company for the trams to be brought into that town, and have consented to petition in favour of the Bill.

**Edinburgh.**—The Corporation have published the statutory notice of their intention to apply for power to reconstruct existing lines, and to lay down new ones for working by some form of mechanical traction. Intimation has been given that it is intended to make application for a provisional order for the purpose of incorporating a company, to be known as the Edinburgh Suburban Electric Tramways, for the purpose of laying down tramways between Craigmillar Park and Eskbank.

**Broughty Ferry.**—A Dundee paper reports that all arrangements in connection with the formation and financing of a public company for the construction and working of the Dundee, Broughty Ferry, and District Tramways have now been definitely completed. Contracts amounting to close upon £90,000, and including the whole of the construction of the tramways and the building of the generating station and car sheds, are stated to have been entered into. Constructive work is to be begun in the early part of May.

**Coventry.**—On Tuesday Lieutenant-Colonel Yorke, C.B., on behalf of the Board of Trade, made an inspection of the extensions of the Coventry and District Electric Tramway Company. Commencing his tour of inspection at the railway station, the car proceeded to Broadgate, down Smithford-street, along Spon-street and Spon-end to the Chapel-street terminus. Lieutenant-Colonel Yorke also inspected the lifeguard and other appliances upon the tram. The Corporation have decided to institute proceedings against the company on account of dilatoriness with other lines.

**South Shields.**—At a special meeting of the Town Council on Wednesday there was a long discussion on the now familiar tram *v.* motorcar question. On behalf of the deputation who were sent to the principal towns to enquire as to the working of motor 'buses, it was reported they had come to the conclusion that that system was unsuitable for a town like South Shields. Councillor Barlow, the electric tram's champion, implied that the superiority of that vehicle was manifested by the deputation's report. It was decided to invite tenders for the laying of the electric tramways, the tenders to be considered at an early date.

**Motor 'Buses.**—At the resumed conference of municipal tramway authorities, Councillor Boyle, of Manchester, presiding, it was reported that the Midland Railway Company had agreed with the Liverpool and Bradford Corporations to insert clauses limiting the running of motor omnibuses to routes beginning or ending at one of the company's railway stations. The conference agreed that Mr. J. H. Whitley, M.P., should move an instruction to the committee dealing with the Bill to extend the clause to the railway's whole system, and also to secure the insertion of a similar clause in the North-Eastern Railway Bill and the Great Western Railway Bill.

**Cardiff.**—A recommendation was made to the Tramways Committee last week by the electrical engineer, Mr. Arthur Ellis, that a medical man should be appointed to examine the men in the employ of the tramways department. Mr. Ellis stated that they had to keep a reserve of 40 men to take the places of those who fell sick. He quoted an instance where a man who had only been in their employ six weeks fell sick, and became entitled to 50 per cent. allowance. Mr. Ellis was instructed to enquire as to the practice adopted by other departments of the Corporation, and to report.

**Kidderminster.**—A letter was read before the Rural District Council on Tuesday from the company which obtained an order to construct a light railway from Kidderminster to Bewdley, stating that they had written to the Kidderminster Town Council expressing disappointment that they had not received some proposals with regard to the operation of car traffic through the Bull Ring at Kidderminster. The cars could not be profitably worked unless there were facilities for passing through the Bull Ring to the railway station and to connect with the Stourport line. As the extended time for carrying out the order expired on the 2nd prox., the company had no alternative but to abandon their order.

**Walsall.**—At the meeting of the Town Council last week it was reported that the receipts for the month had been £1,793. 5s., against £1,801. 11s. 7d. in the corresponding month of last year, but that the receipts had averaged 9·36 per car mile, against 7·87. Wages paid had been £604. 1s. 1d., against £713. 19s. 8d. It was also reported that the old lines had been inspected by Lieut.-Colonel Yorke, R.E., for the Board of Trade, and the Tramway Committee had arranged to carry out his recommendations. The committee have arranged with the borough auditors to prepare quarterly reports as to the undertaking. At present the committee cannot see their way to adopt a system of ½d. fares as requested by the Walsall Trades' Council.

**Exeter.**—The completed sections from Heavitree to St. David's and Paris-street to Pinhoe-road were last week inspected by the Board of Trade. Two cars were run over the sections, and a careful examination made of the wire equipment, cars, and track, especially at the difficult junction of High-street with Queen-street, and the inspectors are reported to have expressed their satisfaction with the result. The Board of Trade certificate is expected in the course of a few days, but the line is not to be publicly opened before April 3. Twelve cars will be used. It is stated that the speed which the inspectors will sanction is nine miles per hour on ordinary track, six miles per hour on steep gradient, the curves to be taken at four miles per hour.

**West Fife.**—The position of matters in regard to the tramway scheme appears to have become somewhat involved. A new development has to be recorded in connection with the tramway scheme of West Fife. The Dunfermline and West of Fife Tramway Company have posted throughout the district the statutory notice of application for a provisional order in April, but they are at loggerheads with the district authorities upon the question of road works. A conference was held the other day, but no arrangement was come to, and the company are considering whether they shall abandon the scheme. Meantime it is reported that a number of Edinburgh gentlemen have come into the field, and it is understood to be their intention to form a company, and lodge application for a provisional order.

**Hastings.**—At last week's meeting of the Town Council the Railways and Tramways Committee reported upon the conference that had taken place with the company. On behalf of the Corporation, it was intimated that the proposed overhead system for the front line would have to be entirely abandoned, and, after discussion, the following form of undertaking, which the solicitors to the company intimated that their clients would be prepared to give on the subject, was proposed on behalf of the company: "During the extended period for completion of the works the company undertake not to apply for powers to use overhead traction on the front line except at the previous request of the Corporation." The committee recommended that, subject to the company also agreeing upon certain details and paying the Corporation's costs of opposing the Bill, the opposition be withdrawn and assent given to an extension until July, 1907, for the completion of the system. After a short discussion the report was adopted.

**The Paris Metropolitan.**—The success of this line appears to have exceeded expectation. The system in operation extends over some 20 miles, which is less than half the total concession. In 1900 the number of passengers (six months only) was 17,680 286; in 1901 the number was 55,282 027; and this has been increasing progressively, the number in 1904 being 140 247,228, making a total of 404 194 341. During the first two months of the present year over 30 867,700 passengers have been carried. When the line was mooted in 1891 the most optimistic estimates for the No. 1 section placed the annual traffic at from 25 000 000 to 30,000,000. In 1904 about 70,000,000 passengers travelled over this section of the line. M. Desplas, presiding at the Paris Municipal Council, pointed out at a recent meeting of that body, that the Paris "Métro," which came into being later than similar enterprises in London, Berlin, and New York, differs from them in that it confines itself rigorously to city traffic alone, not being in any way intended to act as a feeder to the main railway lines.

**Australia.**—The *New South Wales Railway Budget* states that electric traction has been substituted on the Ocean-street tramway, Sydney, for cable haulage, which has been in use for over 10 years. In consequence of the conversion of the King and Ocean streets cable

Digitized by Google

tramway into an electric system, increased motive power has been provided at the Ultimo power-house. For some time past the increasing demands upon the supply of electric force have seriously taxed the resources of the Commissioners. At a cost of over £50,000 they have installed at Ultimo a Parsons turbine-engine of 3,000 h.p., with a speed of 1,500 revolutions per minute. The total power now available is approximately 17,800 h.p., a portion of which will always be kept in reserve for breakdowns. The latest installation has involved 16 additional boilers, bringing the total up to 48, rated at 250 h.p. each. The existing plant has a capacity of 9,775 kw., that of the turbine plant just installed being 1,875 kw. Complaints are made by the Railway Commissioners of the maner in which the poles carrying the electric traction wires in the city and suburbs are disfigured by the bill-posters. A considerable sum of money is annually expended in keeping the poles clean and painted, hence the Commissioners feel annoyed to find that their efforts to make everything connected with the electric system look neat and trim are nullified by the actions of billposters. The Commissioners are determined to prosecute persons detected in affixing advertisements to the electric poles. The City Council has also taken the matter in hand. Directions have been given by the Premier of Victoria that the proposed conversion of the St. Kilda railway line from steam to electric traction shall be referred to the Railways Standing Committee. The South Australian Government is still waiting for a reply to the communication sent to the Adelaide tramway companies regarding the purchase of tramways. The directors of the companies have met, but adjourned without arriving at a decision. A further conference is to be held, at which it is expected a joint reply to the Government will be drafted. Unless the companies are prepared to accept a price for their undertakings which in the opinion of the Government is reasonable, recourse will be had to arbitration.

**Swansea.**—The Corporation Bill to, *inter alia*, enable the Corporation to purchase the Swansea Tramway Company's lines came before a Committee of the House of Commons. Mr. Lloyd, K.C., explained that the company was granted powers in 1874, subject to a clause which gave the Corporation the right to purchase the tramways at the end of 21 years from the date of the authorisation of the tramways or the expiration of any subsequent period of seven years. The company sought further powers in late years, all of them being granted subject to this purchase clause; but in 1882 there was some variation of the terms, so that there were varying periods, at the end of which the Corporation could buy the trams, and the position became somewhat curious; he contended, however, that it was the intention of all parties and of Parliament that when the company came for fresh powers in 1882 they should be allowed 21 years of absolute ownership only in which to develop the undertaking; whilst probably at the end of that time the company might have, if they desired it, a lease for 21 years. The tramways were completed in 1885, and therefore the 21 years would expire in February next. The majority of the company's shares were purchased by the British Electric Traction Company in 1897, and the advisers of the company began to see if they could not put a different interpretation on the section, contending that the real meaning of the section was that in the first place the Corporation could buy nothing for 21 years, that at the end of 21 years they could purchase such portions as happened to fall in, and then grant a lease to the company for 21 years, and that during the lease they could purchase nothing more; and that at the end of 21 years they could purchase such other portions as might fall in at the expiration of seven years, and so on. The result of it all would be that the Corporation would not be able to acquire the trams until 1933. The Corporation went to the Court of Chancery. That tribunal could only say what was the meaning of the words in the company's Act as they stood; they could not enquire into the intention, and the Court decided in favour of the view of the tramway company. Therefore the company said that the clauses in question should be repealed, and the present Bill should be passed so as to give effect to what was the intention of Parliament. The Town Clerk of Swansea (Mr. Thomas) said that the Corporation did not oppose the company's Act of 1882 on the understanding that the whole system of tramways would remain in the hands of the company for 21 years from the date of the completion of the tramways authorised by the Act of 1882. At the end of the 21 years the Corporation were to have the right to purchase the whole undertaking. The object was to bring all the different lines of tramway into line, and to treat the whole thing as one concern. Mr. Balfour Browne, K.C., asked whether the clause, the words of which were said by the promoters not to carry out the intention of the parties, was not in the Bill precisely as submitted to Parliament. Witness replied that a misunderstanding had taken place. Mr. Balfour Browne, on behalf of the company, said that the Corporation did not attempt to appeal from the decision of the Court of Chancery, because they knew that the company were right. Now they said Parliament ought to set the bargain aside and take away the company's property. It was unquestionable that under the decision of the Court of Chancery the company were to be in possession of the tramway for 90 years. The effect of the Corporation's Bill was to take away the property in 1906. As a matter of fact, it was only the last section of the line that would be in the hands of the company in 1993, but whatever that might be, there was the bargain. The Corporation said that they understood something different by it. They should have understood that at the time the Bill was before Parliament. They had acted with their eyes open. After consulting in private for a few minutes the Committee decided that the preamble of the Bill was not proved so far as related to tramways.

## LIGHTING AND GENERAL.

**Maidenhead.**—The Council have sealed a loan of £6,500 for electric light extensions.

**Acton.**—Application is to be made for sanction to borrow £10,000 for hire-purchase and free wiring purposes.

**Baildon.**—The District Council have decided to apply for an electricity supply provisional order within their own district.

**Uxbridge.**—A small committee has been appointed to meet Mr. A. R. Bell, engineer of the electric light company, with regard to wiring the parish church.

**Truro.**—A committee has been appointed to consider and report to the Council on the advisability or otherwise of steps being taken for the provision of an electric lighting plant in the city.

**Hindley.**—The Hindley Electric Lighting Order, 1901, has been referred to a committee consisting of Messrs. H. J. Bouchier, E. Grime, J. Stott, J. A. Neville, H. V. Athron, and T. Southworth.

**Calcutta Electric Supply Corporation.**—The number of units delivered to consumers during the four weeks ending Feb. 24 were 187,706, compared with 123,838 in the corresponding four weeks of the preceding year.

**London Gazette.**—Llewelyn Hugh-Jones, Crypt-chambers, Chester, has been released from trusteeship in the estate of Frederick William Parkes and Edward Sadleir, electrical fitters and engineers, Dingle, Colwyn Bay, Denbigh.

**Telephone Trunk System.**—An additional trunk wire is in course of construction between Dundee and Kirkaldy, which will considerably relieve the pressure on the existing circuits, and result in considerable improvement in the service.

**Bishop Auckland.**—The West Auckland Parish Council have decided to open negotiations with the electric light company with the view to the lighting of the village by electricity. The sum of £120 is devoted to street-lighting at present.

**New Issue.**—American Telephone and Telegraph Company's 4 per cent. collateral trust bonds in this company are being offered through Messrs. Baring Bros. and Co., Limited, at the price of £199 per 1,000dol. bond (equivalent of 96½ per cent. Boston price).

**Flintshire.**—On Thursday Holywell was placed in the Chester area for telephonic purposes, and Holywell subscribers will now be enabled to have free communication with Chester, Buckley, Mold, Flint, and Connah's Quay, and *vice versâ*, instead of fees being paid for each call.

**Paddington Electricity Exhibition.**—An exhibition, which has been organised by the Metropolitan Electric Supply Company, Limited, to show the latest developments of electricity for lighting, power, and heating purposes will be opened at the Queen's-road Baths, Bayswater, W., on Saturday next, the 25th inst., at 12.30 p.m., by the Mayor o Paddington.

**Ealing.**—It has been decided to reply to the Hanwell District Council that the Ealing Town Council could probably supply them with current about six months after receipt of parliamentary power in bulk at 2¾d. per unit, with a rent for special main from their generating station, but that the Ealing Council would not take over the whole of the Hanwell Council's electric lighting responsibilities.

**Stock Exchange.**—Applications have been made to the Stock Exchange Committee to allow the following securities to be quoted in the official list: British Electric Traction Company's further issue of 5,000 6 per cent. cumulative preference shares of £10 each, fully paid, Nos. 356,438 to 361,437; Metropolitan District Railway Company's £537,351 assented extension preference (5 per cent.) stock, and £962,649 unassented extension preference (5 per cent.) stock, in lieu of the £1,500,000 extension preference (5 per cent.) stock now quoted; Oxford Electric Company's further issue of 2,000 ordinary shares of £5 each, fully paid.

**Blackpool.**—The borough electrical engineer (Mr. O. Furness), in his February report, shows a net increase in the works output over the corresponding month of last year of 22,306 units, made up as follows: Private lighting—February, 1905, 91,288; February, 1904, 93,265; decrease, 1,977 units. Public lighting—1905, 16,754; 1904, 17,531; decrease, 777 units. Corporation tramways—1905, 89,372; 1904, 62,122; increase, 27,250 units. Lytham and St. Annes tramways—1905, 4,280; 1904, 6,470; decrease, 2,190 units. Total for month—1905, 201,694; 1904, 179,388; net increase, 22,306 units. The Tramways and Electricity Committee have decided to recommend the Town Council to reduce the price of current to 6d. and 2d., with the alternative of a flat rate of 5d. All consumers whose consumption amounts to less than 5s. in value are to pay 2s. 6d. per annum for rent of meter.

**Mirfield.**—The erection of the sub-station at Eastthorpe, and the laying of mains, etc., have been finally settled. Several tenders (particulars of which appear in another column) were accepted. At the last Council meeting, Mr. A. B. Mountain, the Council's electrical engineer, explained that the Westinghouse tender for the supply of transformers was not the lowest, but the leakage in their transformers was not so great as in those of some of the other companies. Mr. Mountain was instructed to engage a jointer to superintend the laying of the mains, the fixing and reading of meters, and the connecting of consumers. Various cable routes were agreed upon. With regard to the work of excavation for the laying of the mains, Mr. Mountain said his experience had been that it was much cheaper to do the work themselves where it was to be done piecemeal. When several miles of mains had to be laid at a depth of several feet, as was the case in the power company's mains, there might be something in letting the work, but in the case of the Council, the raising and relaying of the pavement flags, which was a matter their surveyor would have to superintend, was the principal item, the laying of the mains in a trench perhaps 1ft. deep being a very small part of the work. The Council agreed that service mains be laid free of charge for a distance of 20 yards from the supply mains. The charges for the supply of energy were fixed as follows: for lighting purposes, 5d. per Board of Trade unit, and for motive power 2d. per Board of Trade unit for the first two hours and 1d. per unit afterwards, providing that the motor is run at three quarters of the full load. Rent will be charged for meters.

Digitized by Google

**Carlisle.**—An agreement has been completed between the Corporation and the Tudor Accumulator Company, Limited, for the maintenance of the battery purchased from them. Since the last meeting eight applications for lights, equal to 490 8-c.p. lamps, have been received.

**Telephone Agreement.**—The telephone agreement with the Government, which is being discussed so much by the various local authorities who own or intend to own the municipal telephones, will be discussed at the annual meeting of the Association of Municipal Corporations at the Guildhall on April 1.

**Salford.**—The Town Council have decided to apply for sanction to borrow £600 to cover the cost of laying cable for lighting purposes. The estimate of £600 is made up as follows: cost of cable, £308; excavating, laying, filling-in, watching, and supervision, £109; carting, £49; reinstating, £62; joint-boxes and jointing, £15; contingencies, £57.

**Perth.**—Negotiations with the view of the introduction of the telephone system to North Perthshire are being revived on the understanding that the monetary guarantee be dispensed with, and that between Dunkeld and Pitlochry 80 "toll" subscribers or 42 "full-rate" subscribers be secured. The system may also be extended to Aberfeldy, provided the necessary support is secured.

**New Firm.**—Mr. W. Arthur Ker, late general manager for Messrs. Paterson, Cooper, and Co., Limited, manufacturers of electrical machinery, will shortly open offices at Edinburgh Life Buildings, 122-128, St. Vincent-street, Glasgow, as electrical and mechanical consulting engineer. Owing to the rebuilding of these premises, Mr. Ker's address, until May 28, will be Patella Works, Paisley.

**Metropolitan Asylums Board.**—The Board on Saturday agreed that application be made to the Local Government Board for their sanction to the Managers inviting tenders for the installation of telephones and fire-alarms at the Gore Farm (Upper) Hospital from six selected firms, and to their entering into a contract or contracts for the execution of the necessary works, without, in the first instance, advertising for sealed tenders.

**Bishop's Stortford.**—The Clerk reported at the last Urban District Council meeting that Messrs. Baker had communicated suggested alterations to the agreement for the transfer of the electric lighting order from the Council to a private company. The original draft had laid it down that the company was to pay the whole costs of the Council, not exceeding £250, and it was now suggested that £125 should be paid to cover the costs already incurred by the Council. It was decided to adhere to the amount of £250.

**Croydon.**—We understand that the Lighting and Electricity Committee have credited the Finance Committee in connection with the estimates for the ensuing year with £2,000 from the electric light undertaking account. The borough electrical engineer's last report upon the progress in the demand for electricity is as follows: current sold this year for public lighting, 47,095 units (corresponding period last year, 45,856 units); private lighting, 120,079 units (100,966 units); traction lighting, 81,675 units (79,006 units).

**Frome.**—A six days' electrical exhibition was opened in the market hall by the Frome Electricity Supply on Monday. The Frome Electricity Supply was represented by Mr. J. C. Wigham (chief engineer to Edmundson's Electricity Corporation) and Mr. F. M. Nicholl, A.I.E.E. (resident engineer and manager). Edmundson's Electricity Corporation commence to supply Frome last July with an equivalent of 3,050 8-c.p. lamps. At the present time the equivalent of 18,000 8-c.p. lamps has been connected to the supply mains, while applications equivalent to about 2,000 8-c.p. lamps await connection.

**Watford.**—The transformers for the arc lamps to be erected in Queen's-road and High-street have now come to hand, and the work of fixing the lamps will be proceeded with at once. With reference to a small arc lamp which has been erected experimentally, the engineer has found that the consumption does not exceed half a Board of Trade unit per hour, and he has arrived at the conclusion that a main road, such as the St. Albans-road, for instance, could be lighted in an efficient manner by means of these arc lamps at an annual cost not exceeding the present one for incandescent lighting other than the first cost of erecting the lamps.

**Exeter.**—The electrical engineer has reported that the cost of production for the past year represents a saving of £1,000 per annum, with an increased output of 10 per cent. The interest and sinking fund required will be met without the aid of the rates, and the extra supply for tramways, motors, and lighting already secured will enable the undertaking to meet all its liabilities in the coming year. The Electric Lighting Committee do not advise the Council to incur the expense of an independent test of the new machinery, but have resolved that the electrical engineer be required to report as to the efficiency of the whole equipment as soon as the work is completed.

**Wisbech.**—The Town Council have received the following letter from the Local Government Board: "Sir,—I am directed by the Local Government Board to advert to your letter of the 21st ult. with reference to the application of the Town Council of Wisbech for sanction to borrow £25,000 for electric lighting purposes, and I am to explain that the matter of the proposed contract between the Town Council and the National Electric Construction Company, Limited, is now under the consideration of the Board of Trade, and that pending the decision of that department, the Local Government Board are not in a position to deal further with the application for loan sanction. Any enquiries with regard to the contract, and matters arising in connection with it, should be addressed to the Board of Trade."

**Battersea.**—On Saturday the electric lighting failed in the principal districts of Battersea shortly before nine o'clock. The police in reserve at the Lavender-hill Police Station were at once sent into the principal streets to preserve order among the traffic and to protect shop and stallkeepers from the light fingered gentry. After ten o'clock the defect at the generating station was remedied and the supply restored. We have received the following details: The 750-kw. generator armature went to "earth" at 8.50 p.m., causing a total extinction of the supply. Unfortunately, on the Thursday night before, a 350-kw. machine broke down in the same way. It was therefore impossible to cope with the demand at that hour in the evening until the area had been split up into districts. By that time the demand was much lighter, and the whole supply was running again at 10.20 p.m.

**Burnley.**—The Electricity Committee of the Corporation have had before them the results of the present financial year, which comes to a close at the end of the month. On the prices obtained—viz., 1.75d. for traction, 4d. for lighting, 3d. and 1d. for motors, and 3d. for public lighting—the net profits will exceed £10,000. The recommendations of the committee are as follows: That the tramways be allowed a rebate for the present year, making the price 1½d. For the coming year the charges will be as follows: tramways, 1.45d.; private lighting, 3½d. flat rate; public lighting, 1½d.; motors, 1¾d. for the first hour and 1d. afterwards. This will bring the average price per unit sold to 1.7d., and the net profit at £4,000, after allowing £2,500 for depreciation. The committee has also decided to purchase more plant, which will comprise a 500-kw. generator, boiler, and condensing plant. A lively attack is expected from the members of the Tramways Committee when this recommendation comes before the Council, their contention being that the reductions should all have gone in their favour.

**Hanley.**—The Electric Lighting Committee reported at the last Council meeting as follows: "The assistant engineer reported a serious breakdown on the low pressure side of No. 6 engine on the afternoon of Feb. 1. The plant was about to be put on load, when the bolts securing the balance weight to the crank broke, the weight being flung against the column, smashing a large hole in each side. The engine was at once shut down, and instructions were given to disconnect the low-pressure side of the engine. The cylinder was firmly supported by timbers, and by the next afternoon the plant was again running on half-load. The cause of the breakage was found to be two defective bolts which had been used to secure the balance weight." The chairman, vice-chairman, and the engineer were empowered to consider tenders for the necessary repairs to No. 6 engine. The committee recommended that the sum of £1,150 be paid to the credit of the district fund account, and that the sum of £204. 2s. 2d., including £198. 18s. 11d. balance from the previous year, be carried forward to the current year's account. Discussion on the accounts was adjourned.

**Bath.**—The Corporation have issued a well-illustrated pamphlet entitled "A Few Facts concerning the Use of Electricity as a Motive Power," and "The Cost of same when taken from the Electricity Supply Mains of the Corporation of Bath." We note that a supply of continuous current at 220 and 440 volts is now available practically throughout the whole of the business area of the city of Bath, current for motive power purposes being sold at 1¾d. per Board of Trade unit. As illustrating the immense economy of small motors where the load is intermittent, two instances are quoted—viz., a small motor is utilised to work a hair-brushing machine at a cost of 2½d. per week, which displaced labour costing over 6s. per week, and the whole of the machinery of a dairy is driven by two electric motors of 5 h.p. and 2 h.p. respectively. The machinery is worked at a cost of 9s. 1½d. per week of seven days. Among Bath firms from whom letters have been received speaking highly of the use of electric motors in their business are Messrs. Mallett and Son, Messrs. Jacob Long and Sons, the Bath and Somersetshire Dairy Company, Mr. James Fortt, Mr. A. Ernest Meyer, Mr. George Bayntun, and Mr. John Collins.

**Arbroath.**—At a special meeting of the Arbroath Town Council on Saturday the following letter with reference to the electric lighting of the burgh was received from Messrs. D. and W. Chapel, agents for the Empire Electric Lighting and Power Company: "Dear Sir,—We observe from the report in the newspapers of the meeting held on the 30th curt. that the Town Council have failed to arrange for a transfer of the order to any other company, and we write to say that we are prepared to advise our clients to deposit the £750 in the hands of a neutral party to be held by him for behoof of both parties, and to be paid to the Town Council on delivery to our clients of a transfer of the provisional order approved and sanctioned by the Board of Trade, the £750 to be repaid to our clients should the transfer not be carried out from any cause whatsoever. We think these are terms which it is the interest of the Town Council to accept, and will be glad to hear from you as early as possible in order that we may communicate with our clients." The Town Council have replied that they adhered to their former decision, but that they would be prepared to continue negotiations with the Empire Company on the lines indicated in their last letter.

**Hastings.**—The borough accountant's abstract of the accounts of the electricity department for the year ended Dec. 31 last is very satisfactory, and shows a great improvement on the previous year. The deficiency on the year's working in 1903 of £951, has been turned into a surplus of £117. In addition to this, £4,980 has been paid off the sinking fund, instead of £4,311, an increase of £669, so that in comparison with last year the department shows an improvement of £1,737. The expenditure shows a slight decrease and the income an increase all round. The cost of generation last year was £6,990, 38·88 per cent. on income, and this year £6,495, or 33·37 per cent. Management expenses decreased slightly from £1,502 to £1,496, with a good decrease in percentage, 8·36 to 7·69. Other items were as follows: Distribution of electricity—1903, £360; 1904, £380 (an increase in total, but a decrease in percentage). Public lamps—1903, £826; 1,904, £893 (4·60 per cent. and 4·59 per cent.). Rents, rates, etc.—1903, £205; 1904, £316. Law charges—1903, £4; 1904, nil. Special charges—1903, £218; 1904, £260. Total expenditure—1903, £10,105 (56·21 per cent.); 1904, £9,870 (50·71 per cent.). On the

Digitized by Google

income side everything had increased except miscellaneous receipts, £76 to £72. The items are: Sale of current—1903, £13,02); 1904, £14,231. Sales under contract—1903, £247; 1904, nil. Public lighting—1903, £4,029; 1904, £4,210. Rental of meters—1903, £653; 1904, £801. Rents receivable—1903, £152; 1904, £153. Total income—1903, £17,977; 1904, £19 467; or gross profits carried down of £7,872 in 1903, and £9 597 in 1904. Against these amounts were written off: Bad debts—1903, £11; 1904, £80. Interest on deposits—1903, £6; 1904, £8. Interest—1903 £4,495; 1904, £4,412. Sinking fund—1903, £4,311; 1904, £4,980; or an increase this year from £8,823 to £9,480. Nevertheless the result gives the deficit on last year of £951, and the surplus on this year of £117. Descending to some of the particular items we find that the £6,495 for generation of electricity is composed of £4,123 for coal and other fuel; £1,112 for repairs and maintenance; £932 for wages at generating stations; and £326 for oil, waste, water, and engine-room stores. Management expenses included £985 for salaries, £56 for stationery and printing, and £453 for general establishment charges. The £14,231 received for the sale of current per meter was composed of 361,811 units at 6d., 10,766 at 3d., 759 at 2½d., and 305,283 at 1½d., with a lamp charge of £3,135. That received by the public lighting includes 228,976 units at 1½d. (£1,431); lamp charge, £1,305; interest and sinking fund, £571; and repairs, etc., £891. The capital account gives the expenditure prior to Dec. 31, 1903, as £131,831. 19s. 3d.; expenditure on machinery, £3,785; on mains, £1,062; transformers, £99; meters, £1,025; electrical instruments, £13; a total of £136,819. The amount raised by loans is £140,494, and from revenue £30. There is a balance unexpended of £3,704. The borough electrical engineer's statement of electricity generated, sold, etc., during 1904 is as follows: Quantity generated in Board of Trade units, 1,044,405; quantity sold, public lamps, 228,976; private consumers by meter, 678,619; total sold, 907,595; quantity used on the works, 21,500; total accounted for, 929,095; not accounted for, 115,310; number of public lamps, 104; total maximum supply demanded, 667 kw. The Gwynne engine supplied with the Wheeler condensing plant is to be practically rebuilt out of revenue.

## PROVISIONAL PATENTS, 1905.

MARCH 13.

**5163. Improvements in electrical conduit fittings.** Samuel Withers, Jabez Griffin, and Arthur Duffield Robinson, 128, Colmore-row, Birmingham.

**5197. Improvements in electric switches.** Max Byng and Herbert John Coates, Peel Works, Adelphi, Salford, Manchester.

**5205. Improvements in and relating to trolleys for electric tramcars and the like.** John William Bradley and John Farrer Mason, 33, Chancery-lane, London.

**5206. Improvements in dynamo-electric machinery for continuous and alternating currents, also means of regulating same.** James Priestnall Naylor, 40, Cambridge-terrace, Robson-road, West Dulwich, London.

**5220. Improvements in cooling devices for vapour electric apparatus.** Percy Holbrook Thomas Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, March 28, 1904, being date of application in United States.) (Complete specification.)

**5226. Improvements relating to electrically-fired internal-combustion engines.** Walter Park Little, 30, South-street, Exeter.

**5229. Improvements in or relating to the regenerative control of electrically-propelled vehicles.** John Smith Raworth, 46, Lincoln's-inn-fields, London.

**5230. Improvements in or relating to the regenerative control of electrically-propelled vehicles.** John Smith Raworth, 46, Lincoln's-inn-fields, London.

**5231. Improvements in or relating to the regenerative control of electrically-propelled vehicles.** John Smith Raworth, 46, Lincoln's-inn-fields, London.

**5232. Improvements in electric current circuit breakers.** Ernest Francis Moy and Percy Henry Bastie, Greenland-place, Camden Town, London. (Complete specification.)

**5259. Improvements in or relating to connectors for electrical conductors.** Arthur Basil Carey, 111, Hatton-garden, London.

MARCH 14.

**5270. Electric alarm, improved apparatus for use in railway signalling and also as a fire and burglar alarm.** James Jennett, 2, Castlereagh-road, Belfast, Ireland.

**5273. Novel or improved insulator for electric traction street poles.** Edwin Downward and James Peter Downward, Longport, Stoke-on-Trent, Staffs.

**5280. Improvements connected with electrical switches, circuit breakers, motor starters, and such like.** Verity's, Limited, and Arthur Edgar Gott, 11, Burlington-chambers, New-street, Birmingham.

**5295. Electromagnetic pump.** Robert Lyon Ibbetson, 1, Fishergate-hill, Preston, Lancs.

**5336. A device for automatically controlling air-compressors or other fluid-pressure generating apparatus driven by electric motors.** John Farrer Mason, 33, Chancery-lane, London.

**5357. Improvements in or relating to the forming of glass seals, especially applicable for hermetically sealing electrical conductors into glass.** Charles Orme Bastian, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**5370. Improvements in and relating to methods of insulating electric conductors.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.) (Complete specification.)

**5371. Improvements in and relating to methods of and apparatus for insulating electrical conductors.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

MARCH 15.

**5398. Improvements in the manufacture of pendants, brackets, and other fittings for gas and for electric light.** Harry Hateley, 122, Colmore-row, Birmingham.

**5409. Improvements in vapour electric apparatus.** Peter Cooper Hewitt, The Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, April 9, 1904, being date of application in United States.) (Complete specification.)

**5419. Improvements in main switches or circuit breakers.** Thomas Reginald Herbert Tetley, Falcon Electrical Works, Poland-street, Manchester.

**5425. Improvements in or relating to electric furnaces.** Henry Livingstone Sulman and Hugh Fitzalis Kirkpatrick-Picard, 111, Hatton-garden, London.

**5447. Improvements in or connected with electrical measuring instruments of the wattmeter class.** Nalder Bros. and Thompson, Limited, and Richard Frank Curtis, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**5456. Improvements in detectors for electromagnetic waves or other weak electric impulses.** William Phillips Thompson, 6, Lord-street, Liverpool. (Gesellschaft für drahtlose Telegraphie m. b. H, Germany.) (Complete specification.)

MARCH 16.

**5489. Improvements in or relating to telegraphic apparatus.** Frederick George Creed and William Arthur Coulson, 46, Lincoln's-inn-fields, London.

**5491. Improvements in electric radiators or heaters.** Sherard Cowper-Coles, Grosvenor-mansions, Victoria-street, Westminster, London.

**5497. A system of signalling between guards of a train and the engine-driver of that train by means of an electric bell or light on the engine operated by a switch at the entrance to each carriage.** Harry Darley Osterfield, 6, Ranelagh-road, Westbourne-square, Paddington, London.

**5520. Improvements in or relating to electric circuit breakers.** Thomas Edgar Weaver, 134, Claremont-road, Manchester South.

**5553. Improvements in and connected with electric arc lamps.** Victor Watson Riley and Herbert William Rowing, Birkbeck Bank-chambers, Holborn, London. (Complete specification.)

**5554. Improvements in or connected with the insulators of the third rail of third-rail electric traction systems.** Franz Gustav Kleinsteuber, 52, Chancery-lane, London.

**5568. Improvements in balance weights for electric light pendants and the like.** Joseph Augustus Bauer, 4, South-street, Finsbury, London.

**5577. Improvements in telephone calls.** Peter Thomas Geyerman 40, Chancery-lane, London. (Comp'ete specification.)

**5582. Improvements in dynamo-electric machines.** Pierre Anton Joseph Lapeyrade, 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, March 17, 1904, being date of application in France. (Complete specification.)

**5583. Improvements in and relating to measuring instruments.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**5584. Improvements in electric conveyor systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**5585. Improvements in and relating to vapour electric apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

MARCH 17.

**5588. Apparatus for cleaning electric lamp globes.** George Hone, 9, Regent-street, Kettering, Northamptonshire.

**5590. Improvements in alternating and pulsating current electromagnets and solenoids.** William James Frederick Cooper, 55, Abbotsford-avenue, West Green, Tottenham, London.

**5643. Improvements in or relating to electrolytic cells.** Edgar Arthur Ashcroft, 111, Hatton-garden, London.

Digitized by Google

**5660. Improvements in automatic electric make and break contacts.** Edward Bettridge Boucher, 21, Finsbury-pavement, London.

**5662. Improvements in and relating to track construction and electric signalling and controlling equipment therefor.** Guion Thompson and Huntington Wolcott Merchant, 1, Queen Victoria-street, London. (Complete specification.)

**5675. Improvements in dynamo-electric machinery.** Leonard Knight Clark, 4, South-street, Finsbury, London.

MARCH 18.

**5685. A new or improved method of electrically transmitting and indicating upon a screen the position of moving figures, moving objects, diagrams, writing, and the like.** John Alexander Kennedy-McGregor, 5, Corporation-street, Birmingham.

**5724. Improvements in dynamo-electric and electro-dynamic machinery.** James Grey Bell, 17, St. Ann's-square, Manchester.

**5755. Improvements in electric switches.** Kenneth Odell Searle, 35, Macauley-road, Clapham Common, London.

**5757. Improvements in and relating to alternating-current electric motors.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.) (Complete specification.)

**5758. Improvements in electric clocks.** George Bennett Bowell, 40, Chancery-lane, London.

**5769. Improved construction of accumulators or secondary batteries.** Alexander Elias Dakhyl and Antonio Galanti, 173, Fleet-street, London.

**5771. Improvements in or relating to printing telegraphs.** John Charles Barclay, 7, Southampton-buildings, Chancery-lane, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published April 6.*

1903.

**27265. Telegraph and like cables.** Lodge and Hardie.

1904.

**5892. Electric lamps of the character known as vapour lamps.** Bastian.

**6319. Electric conductors.** Heany.

**6811. Electrical signalling instruments.** Sullivan.

**6832. Electrolytical extraction of metals from solutions.** Webb.

**10242. High-tension electric current switches.** British Thomson-Houston Company, Limited. (General Electric Company.)

**10525. Driving gear for electrically-driven rotary brushes.** Maclean.

**10812. Overhead trolleys or collectors for electric tramway and railway vehicles.** Blaney.

**10873 Heating by electricity.** Voelker.

**10877. Fluid-pressure brake systems for railway vehicles, trains, and the like.** British Thomson-Houston Company, Limited. (General Electric Company.)

**11116. Electrical signalling.** Hards.

**13107. Switch mechanism for use in connection with inter-communication telephone instruments or telephone systems.** Electric and Ordnance Accessories Company, Limited, and Hall.

**25220. Protective systems for electric distribution lines.** Wilson. (Date applied for under International Convention, Nov. 20, 1903.)

**27904. Secondary batteries.** Gardiner.

**29408. Current distributors for the electric ignition devices of internal-combustion engines.** Renault. (Date applied for under International Convention, Sept. 23, 1904.)

1905.

**136. Electric transformers.** Conrad. (Date applied for under International Convention, Jan. 20, 1904.)

**1754. Electric ignition devices for explosion engines.** de la Valette. (Date applied for under International Convention, Jan. 28, 1904.)

**3433. Devices for exerting an electromagnetic influence on the arcs of electric arc lamps.** Carbone.

## NOTES.

**The McMillan Fund.**—The President announced to the members of the Institution last week that this fund, amounting to £2,082, has now been invested in trustees' securities, in the names of Sir Wm. Preece, Mr. R. K. Gray, and Mr. Alexander Siemens, for the benefit of Mrs. McMillan and her children.

**Manchester Section.**—The annual general meeting of this section will be held at the University on April 11 at 7.30 p.m., when the chairman, vice-chairman, hon. secretary, and 12 members of committee will be appointed for next session. There will also be a paper on "Labour-Saving Formulæ in the Design of Direct-Current Dynamos," by Mr. J. Frith.

**North-East Coast Institution.**—The issue for March of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders contains the adjourned discussion on "A Comparison of Vertical and Horizontal Tubes in Water-Tube Boilers," by Mr. W. R. Cummins, of which paper we gave an abstract in our issue of Dec. 2; and a paper on "The Launch of the U.S.A. Cruiser, 'South Dakota,'" by Mr. Jas. Dickie, with the discussion.

**Improving the Consular Service.**—It is a familiar cry that other countries take the lead over us in regard to consular affairs. An illustration of this is afforded by the action of the German Government in appointing a number of technical and commercial experts as attachés to their consulates in the chief towns of European countries, in order to assist industrial development. The list includes a specially-trained civil engineer for St. Petersburg. This method of fostering trade appears eminently suited to the end in view. It has been advocated for the United Kingdom before now, but the wheel of British consular progress revolves with marked deliberation. Unless our hopes are being flattered only to deceive, the proposed Ministry of Commerce may introduce much-to-be-desired reforms in the consular service.

**Tramway Management.** — The London County Council on Tuesday decided to sanction a vote of £150 for the chief tramway officer to visit the States and see how things are done in the large American cities. This is partly the outcome of the report presented by Mr. J. Allen Baker, the chairman of the Highways Committee, upon his tour in that country last year. The conduit electric tramways of New York having been at work for some time before the County Council's, the greater experience gained has enabled the undertakers to effect considerable economy in working, besides improvements in many details of organisation. Conduit cleaning, tramway stores depôts, and subway trams are other important matters for investigation. There is a tendency now to accept the achievements of our Transatlantic cousins with the proverbial pinch of salt, or even more, but it must be admitted that their enterprising methods seldom fail to provide useful hints.

**Association of Electrical Engineers, Italy.**—We have received part 1 of vol. ix. of the *Transactions* of the Associazone Elettrotecnica Italiana, which contains papers on "Stroboscopic Observations of the Alternate-Current Electric Arc," by Profs. L. Lombardi and G. Melazzo, of Naples; "Formulæ with regard to a Recently-Proposed Phase Meter," by Dr. P. Barreca, of Rome; an essay on "The Influence of Hertzian Waves on the Magnetisation of Steel," by C. Garibaldi, of Genoa; "Observations on the Working of the Magnetic Detector," by Prof. M. Ascoli, of Rome; and a paper, read at the Turin meeting by G. Gola, on "The Analogy existing between Hydraulics and Electricity." All these papers are profusely illustrated with cuts and diagrams. There are also two memoirs on late members—namely, N. Labroca and Prof. A. Cancani-Montani—by O. Lattes. The index gives a balance-sheet and other information in connection with the association, also the composition of the commission appointed to deal with the investigation of the standardisation of electrical measurements.

**Junior Institution of Engineers.**—Visits of this institution have recently taken place to the Brockie-Pell Arc Lamp Works and to the New Ritz Hotel, Piccadilly, where the skeleton-cage system of construction was seen. At the former establishment the members were received by Mr. James Brockie, the inventor of the Brockie-Pell lamp, who gave a very interesting account of its development and construction, and described generally the necessary characteristics of an efficient arc lamp. In the workshops a number of lamps of different types were shown in course of manufacture, and in the testing-room demonstrations were carried out to illustrate the effect on the arc of two methods of regulation — namely, differential and shunt coil only. This served to illustrate that with the shunt coil alone the current might be varied very considerably without affecting the length of the arc, whereas with the differential method the variation in length of the arc was very considerable with the same change in the current strength. The two lamps were run in series, so that each had the same current passing through it.

**Franklin Institute.**—We have received a copy of the March issue of the *Journal* of the Franklin Institute (Philadelphia), which contains papers on "Radium and Radioactivity in General," by Mr. R. H. Bradbury; "Telephone Line Engineering," by Mr. C. J. H. Woodbury; "An Ammeter for High-Potential Currents," by Mr. H. C. Snook; "Determination of Exponents in Adiabatics," by Mr. T. W. Gardner; and "A Simple Method of Calculating Water Analyses and amounts of Substances to be added for Preventing Scale and Corrosion in Boilers," by Mr. S. S. Sadtler. We notice that in the paper on "An Ammeter for High-Potential Currents," the instrument described is an ammeter for measuring currents flowing in the secondary circuits of induction coils. A D'Arsonval system is used, modified by placing a small condenser in parallel with the moving coils and its calibration shunt to compensate for the high-rate change of current, and by a ground on one side of the system to prevent sparking between the meter parts. The instrument is especially adapted for use in X-ray work, because it was found that the quantity of X-rays was directly proportional to the current flowing in the tube.

**Pneumatic Dispatch.**—The Electricity Committee reported to the St. Marylebone Borough Council yesterday that at an interview with the Metropolitan Pneumatic Dispatch Company, the representatives of the latter stated that their scheme would reduce street traffic by 30 per cent, which would be substantial compensation for the inconvenience resulting from the opening of the streets. Possibly there is an element of optimism about the estimate of 30 per cent., but if that figure be approached it will be a distinct factor in the solution of the London traffic problem. The company are willing that a clause shall be inserted in the Bill stipulating that their electric mains shall not be used for any purposes other than those of their scheme. It appears that, if the project is sanctioned, the municipalities are likely to gain a customer for power, as the company are desirous of taking this from the borough councils. The engineers of the company and the St. Marylebone Council are to discuss the question of terms, pending which the Council have deferred any action

Digitized by Google

in the matter. A number of petitions have been lodged against the Bill, though many of them are of a formal character only. The advantages offered by the company's scheme at least merit a fair hearing.

**Canadian Mineral Production.**—The Geological Survey of the Dominion has issued a preliminary statement of the country's mineral production for 1904, which shows the value of the products to aggregate over £12,000,000. This is a slight decrease as compared with the previous year, but it appears to be attributable to a return to normal conditions, the values for recent years having been swollen by the rapid exploitation of the richer and easily accessible portions of the Yukon gold placers. Gold and coal now share first place among the Dominion's minerals, and as each represents 27 per cent. of the total production they constitute together more than half of the country's mineral values. Following these metals come copper, nickel, silver, lead, asbestos, petroleum, and pig iron, in the order named. An electrolytic lead refinery is in operation at the Canadian Smelting Works, Trail, B.C., producing pig lead, lead pipe, sheet lead, etc. Last year 19,000 tons of lead were produced, as against 9,070 tons in the previous year, but the output was a long way behind the maximum of 31,584 tons attained in 1900. Copper showed a moderate advance in production, the falling-off in Ontario being more than made up by the increased yield of the Boundary district and the Coast district of British Columbia. The exports of iron ore were 168,828 tons, valued at £80,000. In addition to the exports, about 180,932 tons were used in Canadian blast furnaces. About 530 tons of zinc ore were shipped during the year.

**Electrical Exhibition.**—The first meeting of the Executive Committee was held at the Hotel Cecil last week, when it was decided that the exhibition should be held at Olympia from Sept. 25 to Oct. 21. Instructions were given to issue the prospectus as soon as possible, many applications for space having been received. Finance and general purposes committees were appointed, and Sir William Preece was unanimously invited to accept the presidency of the exhibition. Messrs. Bridges and Smith, Balfour House, Finsbury-pavement (to whom all enquiries respecting space should be addressed), were appointed managers. The Executive Committee as appointed to date consists of Messrs. S. W. Baynes (St. Pancras electricity works), H. Bevis (General Electric Company), O. H. Bishop (Edison and Swan, Limited), H. W. Butler (Electrical Power Storage Company), E Cunliffe Owen (Metropolitan Electric Supply Company), S. T. Dobson (St. James's and Pall Mall Electric Light Company), T. C. Elder (Brush Electrical Engineering Company), C. S. Northcote (Verity's, Limited), H. Oppenheimer (International Electric Company), W. L. Packenham (Crompton and Co., Limited), W. H. Patchell (Charing Cross and Strand Electricity Supply Corporation), R. Portheim (Bruce Peebles and Co., Limited), and J. E. Kingsbury (Western Electric Company). The Municipal Electrical Association have still to elect their representative. We understand that the enterprise is meeting with cordial support from companies and municipalities all over the country, and this unanimity augurs well for its success.

**Turbines.**—On Monday evening Mr. J. D. Bailie, A.M.I.E.E., delivered a lecture before the Sheffield Society of Engineers and Metallurgists upon "The Parsons Steam-Turbine and its Applications." After tracing in detail the progress of the steam-turbine, Mr. Bailie described various turbine-driven steamers, and presented views and descriptions of the large new Cunarders built by Messrs. John Brown and Co. He showed curve diagrams exhibiting the results of exhaustive trials of the turbine-driven cruiser "Amethyst," as compared with the "Topaze" and other similar vessels driven by reciprocating engines, showing the enormous gain in efficiency due to the turbines and the consequent greater radius of action. With an allowance of 750 tons of coal, the "Amethyst" can travel 3,160 sea miles at 20 knots, as against the 2,140 sea miles of the boats with reciprocating engines speeded up to the same rate. In the course of the discussion Mr. S. E. Fedden (the city engineer) gave some interesting facts about the performance of a 500-kw. steam turbine-generator at the Corporation electric light station, which was bought from the Paris Exhibition, delivered at three weeks' notice, erected and set to work on full load within three days, and kept running for 19 or 20 hours a day for two years without stoppage or need for repair. When opened it was found that not only was there no wear on the vanes, but they had slightly thickened owing to a film deposited on them. The economy of the turbine-generator was fully maintained. He believed that the turbine-generator would take the place of the reciprocating engine for both continuous and alternating current generation.

**Deltabeston Wire.**—In our issue for Jan. 6 we gave a description of some field coils manufactured in the States with asbestos insulating wire to enable them to stand high temperatures. We now hear from the manufacturers of this wire giving us some more information respecting the same. The firm in question is the D. and W. Fuse Company, of Providence, R.I. The wire is insulated with practically pure asbestos, which makes it indestructible as far as temperature is concerned. The information given respecting this material as compared with cotton-covered wire is interesting at the present juncture, when the Engineering Standards Committee's report is under consideration. Thus the D. and W. Fuse Company state that investigations prove that at a temperature of about 147deg. C. cotton-covered wire will in time char to an extent that will break down its insulation. It was further ascertained that at 199deg. C. cotton-covered wire began to smoke in 20 seconds. At 239deg. C. it was distinctly discoloured in 50 seconds, and complete carbonisation had taken place at 245deg. C. in 2 minutes and 15 seconds. These temperatures are, of course, excessive, yet they go to show how short a space of time is necessary to ruin the field or armature windings on a railway motor where subjected as they are at times to enormous overloads. Deltabeston wire tested under identically the same conditions—in fact, subjected to identically the same volume of current—is absolutely unaffected. Reference to our note of Jan. 6 will show that after the coils have been wound with this asbestos insulation they are thoroughly dried, and then immersed in a paraffin insulating compound, which makes them waterproof.

**Cantor Lectures.**—The third of this series of lectures on telephony was delivered by Mr. H. L. Webb at the Society of Arts on Monday last. It dealt with the subject of switchboards. The lecture was largely illustrated with lantern slides, and concluded with what is an innovation—a welcome one—in scientific lectures, a series of biograph views illustrating the actual work in a telephone exchange. Early switchboards naturally partook of the character of telegraphic equipments. No one at first seemed to realise the possibilities of telephonic expansion. Mr. Webb in this lecture described the evolution of the modern switchboard. He commenced with the very earliest forms, illustrating them with models kindly prepared by the Western Electric Company, showing in the first instance the different methods adopted to get signals to and from subscribers. He compared the telephonic system to the nervous system in human beings. One set of nerves sent a call to the brain, another set carried the reply back from the

Digitized by Google

brain. Then came the quick and necessary improvement in switchboard work, till with somewhat complex mechanism the result is simple and mostly automatic. The lecturer successfully combated the idea that a modern telephonic installation was a simple thing, requiring no engineering skill. On the contrary, it is a highly complex matter, requiring great technical skill to design and carry out, and is a power station as well. Another idea that the women employed are given to taking it easy was exploded, the biograph pictures being called in to help. And Mr. Webb was truly right. The modern telephone exchange is a wonderful institution, and allows no laxity either of brain work in the engineering staff or of active physical work in the operating staff.

**"Pertinacious" Currents**—At the Royal Institution last Friday, Sir Oliver Lodge enunciated the nature of the electrical current upon which he has conferred the designation "pertinacious." By this he simply meant a high-potential continuous current, which was obtainable from a voltaic battery with a quantity of cells in series, though that was an inconvenient and expensive method. An alternating-current dynamo could be reversed by means of the commutator, so that an approximately steady current was obtained, but with commutating devices it was not easy to employ high voltages. One way of obtaining high-potential continuous currents was by the use of a one-way rectifier. If a current were taken through the primary of a Ruhmkorff coil and a Caldwell break, and the secondary was connected to a number of Leyden jars, the provision of a rectifier which would allow the supply current to pass one way, but prevent all exit the other way, would enable the jars to be charged to bursting pressure, so that they could maintain a pertinacious current through a leak or other high resistance with which they might be provided. An arrangement of this type was of service for fog dissipation. He suggested that the action of the rectifier was due to the rapid clearing away from the anode of all the carriers of positive electricity, by means of the bombardment from the cathode, and to the fact that the current could only be conveyed by the agency of these positive carriers when they were allowed to come into actual contact with the positive terminal. The bombardment was found in time to create so high a vacuum in the vessel that no current at all could pass. It was therefore necessary to employ in the rectifier a vapour, such as that of mercury, the supply of which could easily be maintained from inside the vessel. Sir Oliver prefaced the lecture with some of his early reminiscences of the Royal Institution, which had acted as an inspiration to him.

**Patents.**—A memorial, with a large number of names eminent in engineering and science attached, has been presented to the President of the Board of Trade with special reference to No. 10 of the regulations which came into force on Jan. 1 last. In a covering letter the petitioners state that the Act of 1902 was designed, as shown by Section 1, to afford both to the inventor and the public the benefit of an official examination as to novelty, without incurring the serious risk of inflicting injury upon the inventor by refusing a patent for alleged want of novelty or by making public adverse official opinions. Rule 10, however, appears to be based upon the assumption that the Patent Office is charged with the function of publishing an official opinion to the world by placing an endorsement upon the specification whenever it appears to the examiner or comptroller that no patentable invention is disclosed, instead of merely requiring the applicant to mention any prior specification a knowledge of which might be deemed necessary to enable the public to form an accurate opinion. This latter seems to represent the intention of the Act of 1902, and the petitioners consider that Rule 10 is *ultra vires*, besides being unjust. The oppressiveness of the regulation is accentuated by the fact that an examiner, or even the comptroller, while acting with the best possible intentions, might well err in construing an invention as an anticipation when experts have disagreed upon similar points. We think that with the exception of this clause the new regulations mark an advance upon our previous legislation, but it is surely sufficient for an inventor to refer to any prior specification without handicapping him in the commercial world by denoting his patent with an official expression of opinion. We hope, therefore, the President of the Board of Trade will see his way to comply with the prayer of the memorial by amending Rule 10, even if a short enabling Act be necessary.

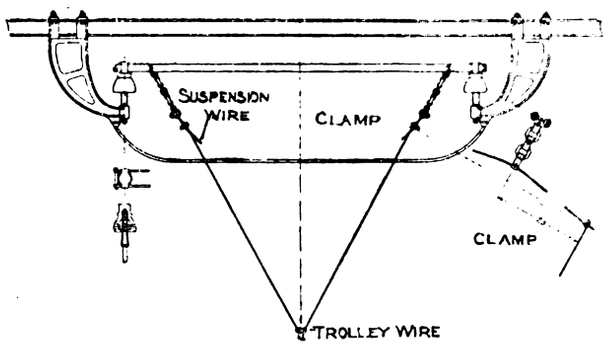
**Radioactivity.**—Concluding his course of lectures on the "Electrical Properties of Radioactive Substances" at the Royal Institution on Saturday, Prof. J. J. Thomson discussed in the first place the energy given off by radium. He pointed out that most of it was contained in the $\alpha$ particles, which contained such a quantity of energy that it could easily be detected by electrical methods, even when the rays were emitted at the rate of only one a minute, the test being infinitely more delicate than anything that could be accomplished chemically. Dealing with the recently-discovered $\delta$ rays, the lecturer explained that they were certainly given off by an alloy of sodium and potassium under the influence of light, and perhaps without light. Rubidium yielded them still more freely, and probably they were also emitted by substances not classed as radioactive. Prof. Thomson observed that in radium the particles as a whole were behaving in a commonplace manner, but here and there some of them were undergoing the change that was the source of radioactivity and were suffering a breaking-down process, which had already been traced through several stages It was only at the end of its career, after persisting unchanged for centuries, that the radium atom showed any peculiar properties. Incidentally, the lecturer deduced from this a warning against assuming too hastily that because a phenomenon, such as the rising of the sun, had happened an indefinite number of times in the past, it was therefore going to continue indefinitely in the future. Prof. Thomson concluded by considering whether radioactivity is a widely diffused property or is confined to a small number of substances. The question was complicated by the fact that naturally radioactive bodies imparted the property to other substances, but he thought the investigations carried on in the Cavendish Laboratory, Cambridge, demonstrated that many common-place substances were intrinsically radioactive, though in a very small degree.

**The Optical Convention**—The arrangements for this convention are now beginning to assume definite shape. The convention will be formally opened with an address from the president, Dr. R. T. Glazebrook, director of the National Physical Laboratory, on Tuesday evening, May 30, and the gathering will extend over the four following days, up to and including Saturday, June 3. The mornings will be devoted to papers and discussions, and in view of the interesting series of papers already announced, it is expected that this most important section of the proceedings will result in valuable contributions to optical science, and will fulfil the aims which those who have been active in promoting the convention have set before them. In addition to the papers, including one on "The Polarisation of Light," by Prof. S. P. Thompson, demonstrations of apparatus of special interest will be given in the afternoon in the laboratories

Digitized by Google

of the department of technical optics of the Northampton Institute. The exhibition of optical and scientific instruments will be held in the large hall of the Northampton Institute. To ensure adequate treatment, it has been arranged that each section shall be dealt with by an expert in the construction of the instruments represented in the section, together with an independent scientific member of the committee. The catalogue is now in active preparation, and the hon. secretary would be glad to hear from firms wishing to take a number of catalogues for private distribution. The social side is not being lost sight of, a hospitality and entertainments committee having been formed. Amongst other things, this committee is arranging for a conversazione and for the attendance at the convention of visitors from a distance. It is also proposed to pay a visit to the National Physical Laboratory at the invitation of Dr. Glazebrook. The hon. secretary is Mr. F. J. Selby, Elm Lodge, Teddington, and the secretary of the Local Societies' Committee is Mr. W. Rosenhain, 443, Gillott-road, Edgbaston, Birmingham, to whom all communications respecting the attendance of visitors from a distance should be addressed.

**Single-Phase Railway.** — Nieder-Schoneweide and Spindlersfield, Germany, have recently been connected by a single-phase railway, of which a description appears in our New York contemporary, *Electricity*. The line, which is about three miles in extent, was constructed by the Union Elektricitäts-Gesellschaft, of Berlin. Current is generated at a tension of 6,000 volts and a frequency of 25 cycles per second. Some features of interest are presented by the overhead equipment. On some portions of the line a method of single suspension is in use for the overhead conductors, the line being suspended from side bracket arms. In other places double bridle wires are employed. From the accompanying illustration it will be



seen that the wire is supported freely, and yet so as to provide against a failure of one of the suspension wires. Short lengths of wire connect the trolley wire to the bridle wires, which are in turn supported by rubber chains from a bar insulated from the bracket arm. The bar below the bridle wire is connected to the metal pole and thence to the rails. In case of the failure and breakage of one of the suspension wires it would touch this earthed bar, producing a short-circuit and throwing out the circuit breaker protecting the line. It can be seen from this that with the double-suspension system great safety is insured. Telegraph and telephone wires passing over the trolley wire are completely surrounded by a wire cage, which keeps them from coming into contact with the high-tension line. Where passing under steel girder road bridges, heavy insulators mounted on a wooden framework are used.

**Commutator Brush holder.**—A form of commutator brush-holder has been designed by Mr. Ernst Woehr, of Wilkinsburg, Pa., for obviating the disadvantage of the box-tight brush-holder. In the latter, unless a spring is used which takes up a great deal of space, the pressure of the brush against the commutator becomes rapidly lessened as the brush wears away. In Mr. Woehr's arrangement, which is described in the *American Electrician*, the brush is pressed towards the toggle links, 6 and 8, pivoted to the framework at 5, and having the knuckle at 7, as shown in Fig. 1. A spiral spring, 9, pulls on the link, 6, and forces

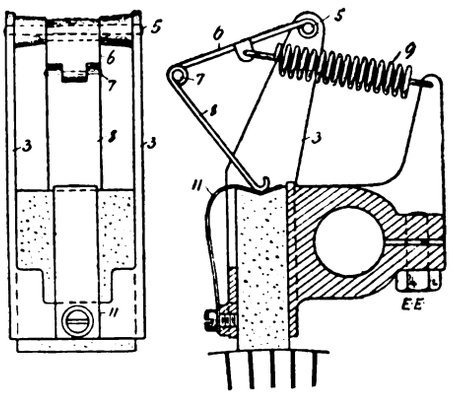


FIG. 1.

the brush downward. As it wears away, and the lower end of the link, 8, follows it down, the toggle angle becomes greater and greater, increasing the leverage of the spring, 9, over the toggle sufficiently to compensate for the decreased pull of the spring as the spirals contract. A thin conducting leaf, 11, is secured at one end to the brush box, and its other end is pressed against the upper end of the brush by the toggle link, 8. A modification in which two toggles are used, the two being drawn together by a spring attached to both, is illustrated in Fig. 2. The lower ends of the links, 8 8, are connected by a pivot, the pivot pin being

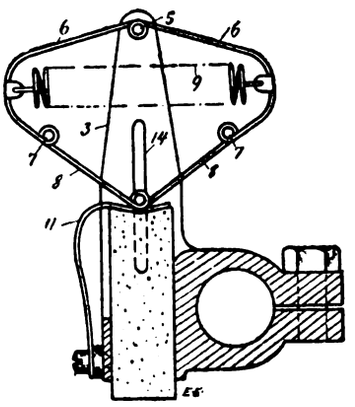

FIG. 2.

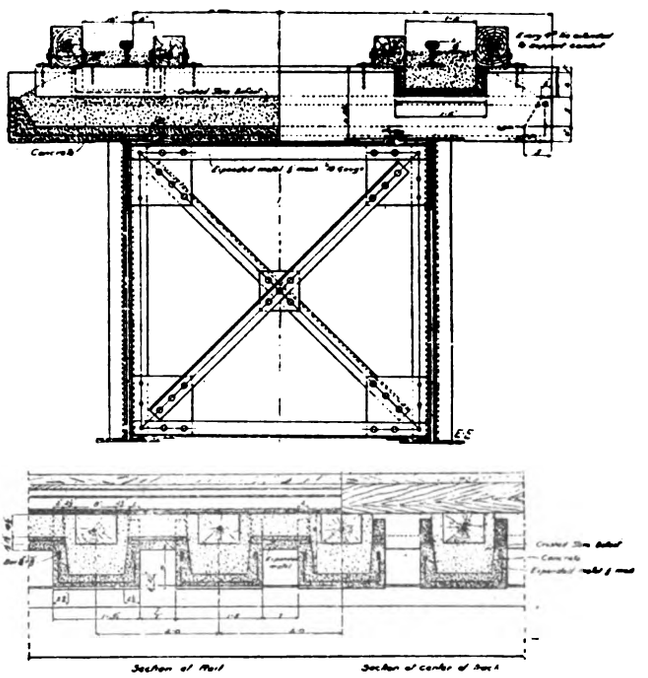
extended through a guide slot, 14, to keep the ends on the middle of the brush end, which is shaped to facilitate this in both forms of the device.

**The Institution.**—The joint discussion on Mr. E. H. Rayner's and Mr. R. Goldschmidt's papers, entitled respectively "Report on Temperature Experiments at the National Physical Laboratory" and "Temperature Curves and the Rating of Electrical Machinery," occupied the attention of members at last week's meeting. At the previous meeting Dr. Glazebrook, as director of the National Physical Laboratory, had briefly reviewed the experiments carried out there, and expressed a hope that they would prove of service to the industry. On the discussion being resumed, the ball was opened by Dr. S. P. Thompson, who, after congratulating Mr. Rayner upon producing an admirable paper, proceeded to attack Mr. Goldschmidt's formulæ, albeit in the most friendly spirit. The paper, said the professor, was a distinctly valuable one, and he only desired to ask the author to render it more so by elucidating a few matters of detail. In one respect he thought Mr. Goldschmidt's calculations could be mate-

Digitized by Google

rially simplified, as the number of watts necessary to produce any temperature rise on the assumption that no heat is being given off by radiation can be ascertained by first principles from the specific gravity, specific heat, and calorific value. The next speaker was Mr. Hobart, who, getting off the mark at a quick pace, maintained express speed throughout. He complimented Mr. Rayner upon his investigations, which must have involved a great deal of work, but he suggested that more diversity might have been introduced into the methods employed. Then Mr. Miles Walker gained appreciation by enunciating a method of calculating the temperature of field coils by deduction from, say, the first two factors. The other speakers were Messrs. R. F. Berry, F. S. Russell, A. Russell, and J. S. Peck, the general tenour of the discussion being favourable to the authors, though a certain degree of misapprehension on various points appeared to exist. Replying, Mr Goldschmidt and Mr. Rayner in turn gave a concise review of the matters in question, the latter remarking that he had found Prof. Thompson's suggested method of ascertaining approximately the watts required to produce a certain temperature rise unsuitable. Preparatory to submitting a vote of thanks to the authors, which was carried unanimously, the President said that Mr. Rayner's paper was a highly valuable one, especially if taken in conjunction with the report of the Engineering Standards Committee. He had been much struck with the fact that the insulation resistances of the cotton-covered field coils remained constant for a certain time until the temperature of the wire began to rise, and then it went down in the most extraordinary way when the moisture was being driven out. This would account for a lot of failures in field coils in the earlier days. Mr. Goldschmidt's paper afforded confirmation that much greater work could be obtained from a dynamo for a short time than under the permanent conditions.

**Overhead Railway Vibration.**—Mr. Bion J. Arnold has recently made an extensive report to the Chicago City Council upon the best way of increasing the capacity and reducing the noise of the Union Elevated Railroad. The first part of the report deals with local conditions, which would not interest our readers so much as that which deals with a reduction of noise. It suffices to say, therefore, with respect to this first heading that Mr. Arnold advocates power mechanism for operating the switches and signals in the congested loop of the railway. He also advises an increase in the length of the stations, which will permit of longer trains being used, and the provision of more sidings at the points where certain branch lines approach the loop. With respect to the noise caused by the trains on this elevated structure, it is pointed out that a good deal of this comes from the trains, and hence cannot be entirely eliminated by any alterations in the track structure. The best, therefore, that can be done is to minimise the noise caused by the operation of the trains, and prevent it being intensified by supplementary vibrations set up in the structure and supports. Mr. Arnold reviews the various types of construction which have been used abroad, including that of the Liverpool Overhead Railway, and comes to the conclusion that a ballasted track is essential if noise is to be kept down. In the case of the Chicago Elevated Railway the rails rest immediately upon the ties, which in turn are rigidly secured to the upper chords of latticed steel trusses, thus giving the best condition that could have been devised for imparting the hammer blows, caused by the wheels upon the rails, directly to the structure, unless the rails had been placed immediately upon the upper chords or upon a metallic support between the rails and the chords. Mr. Arnold reports that if the structure had to be rebuilt, he would advocate the use of concrete throughout as a noise preventer. Under the existing conditions, however, he suggests that a ballasted floor should be provided on the present structure. The floor itself would be formed either of wood or reinforced concrete. The wooden type of floor has been tried experimentally on the Boston Elevated Railway with a marked effect towards deadening the sound. A steel floor could be used, but this is objectionable, not only because of the noise, but also because the steel is in a position where it is exposed to corrosion from water, oil, and greases, which find their way down through the ballast. The concrete floor is free from these objections, and when reinforced with expanded metal can be made in sections and afterwards placed in position. The principal objection to its use, apart from the cost, is that it would obstruct the light, and also give trouble from snow in the winter. In this respect the Liverpool Overhead line is an example of how the snow difficulty has been overcome, and Mr. Arnold thinks that snow-collecting devices could be used with success in Chicago. The increased weight of the



floor, as compared with the present means of supporting the rails, varies from 1,680lb. per lineal foot of track to 1,080lb. The increased weight would mean increased stresses in the structure, but it is pointed out that there would be at the same time a considerable reduction of impact, due to the blows being distributed over a wider area. The report advises that three forms of construction should be tried experimentally at Chicago. The first of these would have a wooden floor, and the other two would have floors made of concrete. Besides this, experiments would be made with three different forms of ballast, in order to see which was most effectual in reducing noise. After this has been done and the best construction determined, the whole of the lines in the centre of Chicago could be altered. Mr. Arnold claims that the experience gained in the application of ballasted floors to railroad bridges has shown that the track maintenance has been reduced to such an extent that the saving is more than sufficient to pay the interest on the increased investment made necessary by its adoption. The illustration herewith shows one form of floor which the report recommends should be tried. In this it will be seen that the sleepers carrying the rails rest on ballast, which in turn is carried by the reinforced concrete.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

(*Continued from page 403.*)

### Multiplex Two-Circuit Windings.

**Double Winding Doubly Re-entrant.**

Suppose we had a machine like Fig. 14, which, though it gave its right voltage and current, was not satisfactory as regards its commutation. We should think immediately that the commutation would be improved if we had more commutator sections. But we cannot get more, as we already have the maximum—*i.e.*, one section for every pair of inductors. The obvious thing to do, then, is to use in place of each inductor two inductors, each of half the section of the original. Or, in other words, place another winding upon the armature in system exactly similar to the present one, and thus double the number of sections. To show how this may be carried out, one or two inductors have been placed on the armature of Fig. 14 at G, H, K. And from this it is clear that the commutator to which this new winding is connected may either be entirely independent of the original commutator (say at the other end of the armature), or it may have its sections interleaved with those of the original winding. Thus the segment attached to H K would come next to that of 1—6, as shown dotted. Similarly that belonging to L and M would fall next to that attached to 2—15. If each brush be wide enough to touch at least two sections, the two windings so arranged will be constantly in parallel with respect to the brushes and the external circuit; and on account of the greater number of commutator sections the commutation is performed more gradually, and is likely to be more satisfactory.

Such an arrangement is called a two-circuit double winding, and since each winding is independent of the other, it is doubly re-entrant, and has the symbol o o. This and the single winding first described, are entirely analogous to the double winding of Fig. 10 and to its corresponding single winding respectively.

**Effect on the Previous Formula.**

It is interesting to note the effect of adding this other winding on the general formula.

Between every pair of the original inductors is one of the new ones, as H between 1 and 2. So that $w$ is twice what it was. Similarly, if the inductors be numbered consecutively, 6 becomes 11 and K becomes 12, etc.

The first winding goes:

$$1 \text{ ——} 11 \text{ ——} 21 \text{ ——} 31 \text{ ——} 5,$$

and the second winding goes:

$2$ —— $12$ —— $22$ —— $32$ —— $4$, where H = 2, K = 12, etc.

Each has a pitch of 10: an *even* pitch. And if the original single winding had $w$ inductors, it was according to the formula

$$w = p\,y \pm 2$$
$$18 = (4 \times 5) - 2,$$

and the new winding is

$$2w = p \cdot 2y \pm 4$$
$$36 = (4 \times 10) - 4.$$

We notice in this formula that not only are $w$ and $y$ doubled, but also the creep, so that the formula for such a case may be expressed by

$$w = p\,y \pm 2m,$$

where $m = 2$.

**Multiplex Windings of Multiple Re-entrancy.**

Similarly, had we wished to treble the number of commutator sections, we might have done it by splitting the winding of Fig. 14 into three parts: then between inductors Nos. 1 and 2 there would be two inductors, as H and another one. The formula becomes

$$3w = p \cdot 3y \pm 6,$$

or writing $w$ for the *total* number of inductors and $y$ for the new number-pitch,

$$w = p\,y \pm 2m,$$

where $2m$ is still the creep and $m$ is the number of independent windings.

For two-circuit armatures, then, where each winding is independently re-entrant, we have the general formula:

$$w = p\,y \pm 2m,$$

where $w$ is equal to the *total* number of inductors;

$p$ is the number of poles;

$y$ is the mean number-pitch; and

$m$ is the number of windings.

Again, since $w$ was before (and must always be) divisible by 2, now in the case of a double winding doubly re-entrant must it be divisible by 4, there being two similar windings on the armature; and this is independent of the number of poles. For a triple winding triply re-entrant $w$ must be divisible by 6, and so for $m$ independent windings $w$ must be divisible by $2m$.

**Question of Odd or Even Number-Pitches.**

We have just found that in the double winding with 36 inductors the number-pitch worked out at 10, an even number, yet it was not necessary to take two number-pitches alternately,

$$y + 1 \text{ and } y - 1,$$

as was done in the case of the single winding of Fig. 19.

The reason of this is that $10 = 2 \times 5$—*i.e.*, is twice an odd number so that it is simply a case of two simplex windings having $y$ = an odd number.

Now if we double the winding of Fig. 19, inductor No. 8 in that diagram becomes No. 15, and inductor No. 13 becomes No. 25.

This shows clearly that the armature of this diagram might be connected as a double winding doubly re-entrant, each winding having two even number-pitches—viz., 14 and 10; $w$ in this case becoming 44. Though this is quite correct, it is better to have resort to the formula, from which we find that a double winding may be arranged with the same number of inductors (44) and $y$ = 10, and for the reason just given 10 is suitable without taking different pitches at the two ends of the armature.

Thus it would be preferable to connect this double-wound armature according to the scheme:

$$1 \text{ ——} 11 \text{ ——} 21 \quad 31 \quad 41, \text{ and so on.}$$

In all cases, when changing over from a simplex winding to a duplex winding, such points as enable a cheaper armature to be manufactured should be constantly looked for. We shall collect these results when we have examined multiplex windings of other re-entrancies.

**Multiplex Two-Circuit Windings of Various Re-entrancy.**

It has been shown that a double winding which is doubly re-entrant is just like two simplex windings placed on the same armature. It follows, therefore, that when considered as one winding (not as two separate windings), the number of inductors being in

Digitized by Google

each simplex armature divisible by 2, the total must be divisible by 4; from which we gather also that the number-pitch, whether odd or even in each simplex winding, must in the duplex be an even number. Now, it is also noticeable in Fig. 21, which represents such a duplex doubly-re-entrant winding, that if connection A were lengthened so that it joined on to inductor No. 2, while connection B is shortened, so that it takes the place of A on inductor No. 1, the winding is not in the least interfered with, since inductors 1 and 2 are at all times practically at the same potential and carrying the same current. Such a procedure, however, has two serious drawbacks; since, in the first place, it introduces two odd end connections, and, in the second, it destroys the independence of the windings. Arrangements of this exact type are not, indeed, found in practice; but it is clear that such an armature might exist, and that, though it would still be *duplex*, it could not be called *doubly re-entrant*. We should, in fact, class it as similar to the multiple-circuit winding of Figs. 12 or 13, being, like them, double, yet singly re-entrant.

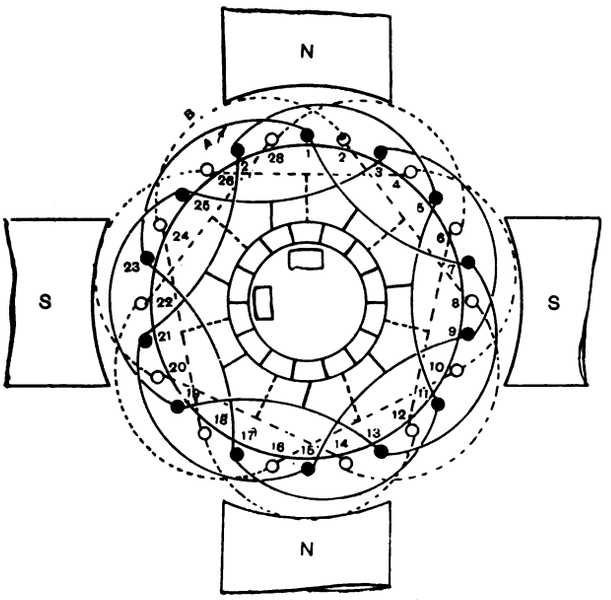

FIG. 21.

It is possible, then, to have a two-circuit double-wound singly re-entrant armature, and though, in the case above cited, there are of necessity two irregular connections, yet if we look at the reasons which cause an armature to be doubly re-entrant, we may be able to devise a method of arranging the end connections without this disadvantage.

**Reason of Independent Windings.**

Fig. 21 shows pretty clearly why the armature is doubly re-entrant.

*It is because any connection such as that from 25 to 3 is greater than the* creep *by an even number of inductors (in this case two).*

Or we may express it thus: In Fig. 21 the number-pitch is 6, and the total number of inductors 28.

Substituting in the formula these numbers,

$$w = p.y \pm 2m,$$

$$28 = 4 \times 6 + 4,$$

or $$2 \times 14 = (4 \times 3 + 2)\,2.$$

The formula thus shows that the number-pitch and $m$ have a common factor = 2, or, in other words, the armature may be resolved into two simplex singly re-entrant windings, each having 14 inductors and a number-pitch of 3.

Thus:

Either winding only picks out every other inductor, leaving the alternate inductors for the other winding. If, then, we could arrange the relationship between the pitch and the creep to be such that while the creep is still kept, that of a double winding—*i.e.*, 4—the difference between the pitch and the creep is such as shall take in, *not* every other inductor, but *all* of them, we should probably obtain the arrangement we seek. So long as the difference between the number-pitch and the creep is an even number, so long can only, at most, half of the inductors be included in any single winding. For the creep is of necessity an even number: therefore the number-pitch under these conditions must also be an even number, which means that either only the odd or only the even numbered inductors can be included in any single winding, as has already been frequently pointed out.

*(To be continued.)*

## ILFORD ELECTRICITY WORKS.

### Opening of Extensions

**On Thursday of last week there was a function at Ilford to celebrate the completion of large extensions in the electricity works there. In our issue for May 24, 1901, there will be found a full description of these works, which were opened in April of that year. Since then the history of the undertaking has been satisfactory, as the progress has been rapid both as regards lighting and traction. Thus, when the works were opened in 1901, the plant in the generating station consisted of two 200-kw. and one 100-kw. sets, each consisting of a high-speed Willans engine coupled to a multipolar generator by the General Electric Company, Limited; one booster balancer set by the General Electric Company, Limited; two batteries of 135 cells each by the Electrical Power Storage Company, Limited; three water-tube boilers by Messrs. Babcock and Wilcox, Limited. The number of consumers increased so rapidly from the commencement of the supply that it was soon found necessary to increase the capacity of the plant, and a fourth boiler was erected in March, 1902. Early in 1902 it was decided to instal two 550-kw. sets, and these were erected and completed by Messrs Dick, Kerr, and Co., Limited, in March, 1903, when the supply of current to the tramways was started. At the same time two additional boilers of the marine dryback type were installed by Messrs. J. Fraser and Sons, each of these boilers being equal in capacity to two of the boilers originally fixed. The first condensing plant and cooling tower were supplied and erected by Messrs. W. H. Allen, Son, and Co., Limited, in September, 1903. The original plant and these extensions were all carried out under the advice and superintendence of Messrs. Hawtayne and Zeden, consulting engineers to the Council.**

**Owing to the continued success of the undertaking and the rapid increase in the demand for current, the Council decided in December, 1903, to proceed with further extensions, and in July, 1904, obtained the sanction of the Local Government Board to a loan of £41,693 for this purpose. Specifications were prepared by Mr. Arthur H. Shaw, M.I.E.E, electrical engineer to the Council, and tenders were invited and contracts entered into in July, 1904, for the supply and erection of the various plant required. The extensions which have now been completed include the following plant: (1) 1,000-kw. multipolar generator by the British Westinghouse Electric and Manufacturing Company, Limited, direct coupled to a triple-expansion condensing engine of 1,600 h.p. by Messrs. Belliss and Morcom, Limited. This set is designed to run at a speed of 200 revolutions per minute, and to give an ordinary output of 2,000 amperes at 500 volts.**

**The condensing plant consists of a surface condenser capable of dealing with 27,000lb. of steam per hour, a**

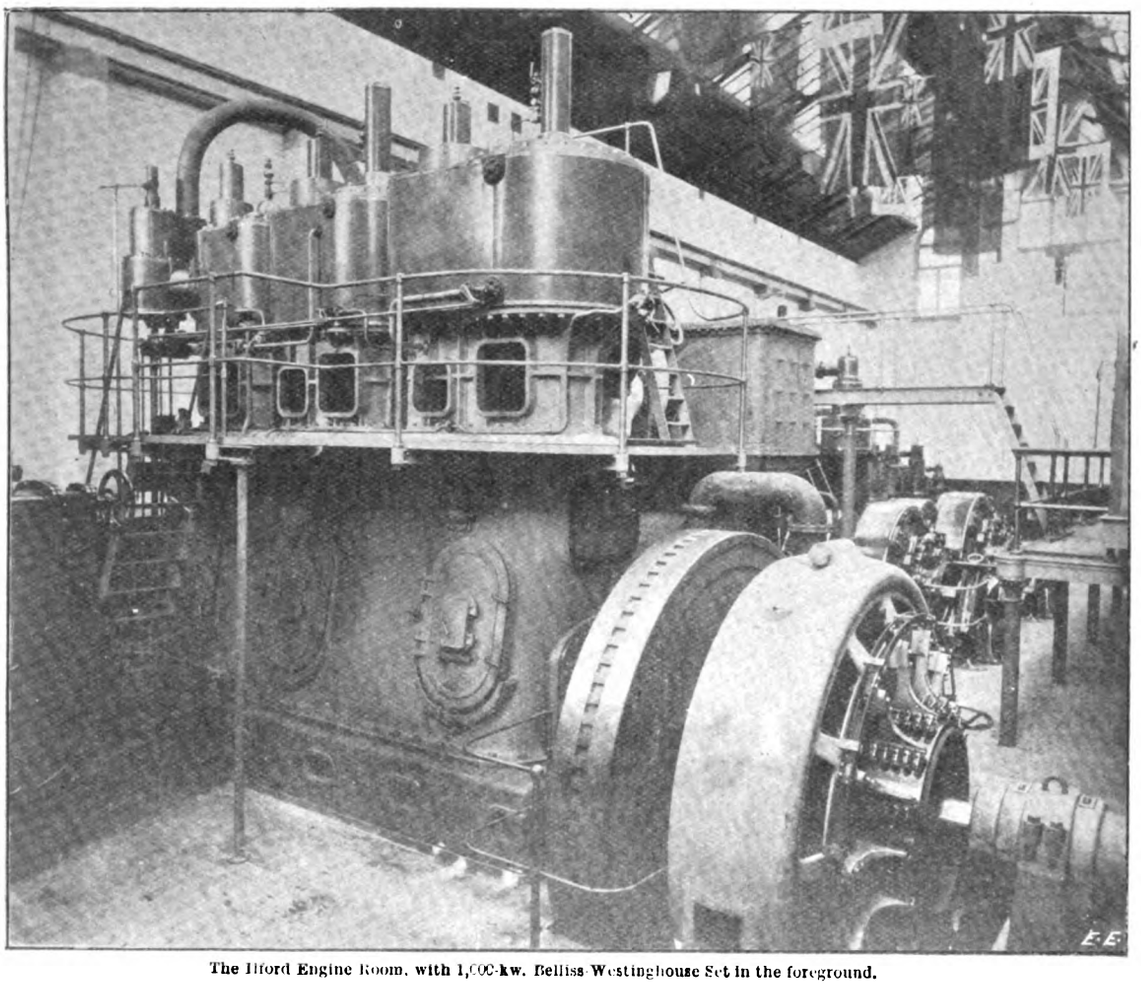
Digitized by Google

grease separator of Messrs. Holden and Brooke's make, motor-driven air and circulating pumps, Zschocke water-cooling tower, and pipework in connection therewith. The condenser, pumps, and motors are of Messrs. W. H. Allen, Son and Co.'s make, and the whole plant was supplied and erected by Messrs. W. H. Allen, Son, and Co., Limited, and is similar to that supplied by them in 1903. The pipework is so arranged that either condensing plant may be used in connection with either cooling tower, and also that either condenser may be used in connection with the new engines, or with the main exhaust of the smaller engines. Provision is also made for running any or all of the engines with exhaust to atmosphere.

The extension switchboard panels for use in connection with the new plant, together with all instruments and cables, were provided and erected by Messrs. Kelvin and James White, Limited, who have also provided the works distributing board, from which independent circuits are run to all the auxiliary station plant, such as boiler feed pumps, condensing plant, station lighting, etc., so that the current taken by each individual portion of the plant may be separately measured. The British Westinghouse Electric and Manufacturing Company, Limited, have also supplied the balancer set and switchboard in connection therewith, which is of sufficient capacity to deal with any development in the future. They have also supplied the reversible booster set and switchboard for use in connection with the battery on traction load, by which it is anticipated a considerable saving will be effected.

A water-purifying plant has been erected by Messrs. Lassen and Hjort in the yard, adjoining the engine-room, for dealing with the condensed water from the engines. By its use all trace of grease and other deleterious matter which may be contained in the water is eliminated, and a perfectly pure water obtained for the boilers, whereby the life of the boilers will be increased, and the labour on boiler cleaning much reduced.

The extensions to the engine-room and switchboard gallery have been carried out to the designs of and under the superintendence of Mr. H. Shaw, A.M.I.C.E., surveyor to the Council—the former by Messrs. F. and A. Wilmott, and the latter by Messrs. Norton Bros. A gangway has been erected connecting the switchboard gallery with the boiler-house, giving the engineer on duty direct access to the boiler-house. The steel tower and separating tank in the yard have also been supplied and erected by Messrs. Norton Bros. The water from the well will be raised by compressed air to this tank, where the air will be separated from the water, which will then flow by gravity to the tramway tank and to the large tank recently erected at the Council's new depôt. An Ados $CO_2$ recorder has been installed in the boiler-house, by means of which samples of the flue gases are taken at frequent intervals and analysed, the result being marked on a chart showing whether the coal is being fired to the best advantage or not. Coal-bunkers have also been provided, and a weigh-bridge installed at the entrance to the yard; the yard itself, opposite the boiler-house, being paved with scoriæ setts.



The Ilford Engine Room, with 1,000-kw. Belliss-Westinghouse Set in the foreground.

The following table will give some idea of the progress of the undertaking from its commencement:

TABLE SHOWING PROGRESS OF ILFORD UNDERTAKING.

| Years ending March 31. | Units sold. | | | No. of consumers | No. of equivalent 8-c.p. lamps connected. | Capacity of plant. | |
|---|---|---|---|---|---|---|---|
| | Lighting | Traction. | Total. | | | Kw. | H.P. |
| 1902 | 403,144 | — | 403,144 | 424 | 16,919 | 500 | 900 |
| 1903 | 749,576 | 22,613 | 772,189 | 1,070 | 36,230 | 1,600 | 2,500 |
| 1904 | 1,077,370 | 563,464 | 1,640,834 | 1,475 | 48,450 | 1,600 | 2,500 |
| 1905 (estimated) | 1,273,715 | 573,300 | 1,847,015 | 1,950 | 58,000 | 3,600 | 4,100 |

The inauguration of the new large generating unit was celebrated on Thursday. The chairman of the Lighting Committee, Councillor John Bodger, presided, and called upon Mr. A. H. Shaw to give a description of the new works. The chairman of the Ilford Council was then asked to declare the works open and to start the machinery. This Councillor R. Stroud, J.P., proceeded to do, after

Digitized by Google

complimenting all concerned on the progress of the undertaking. The rest of the proceedings were devoted to votes of thanks, the contractors being included in this honour.

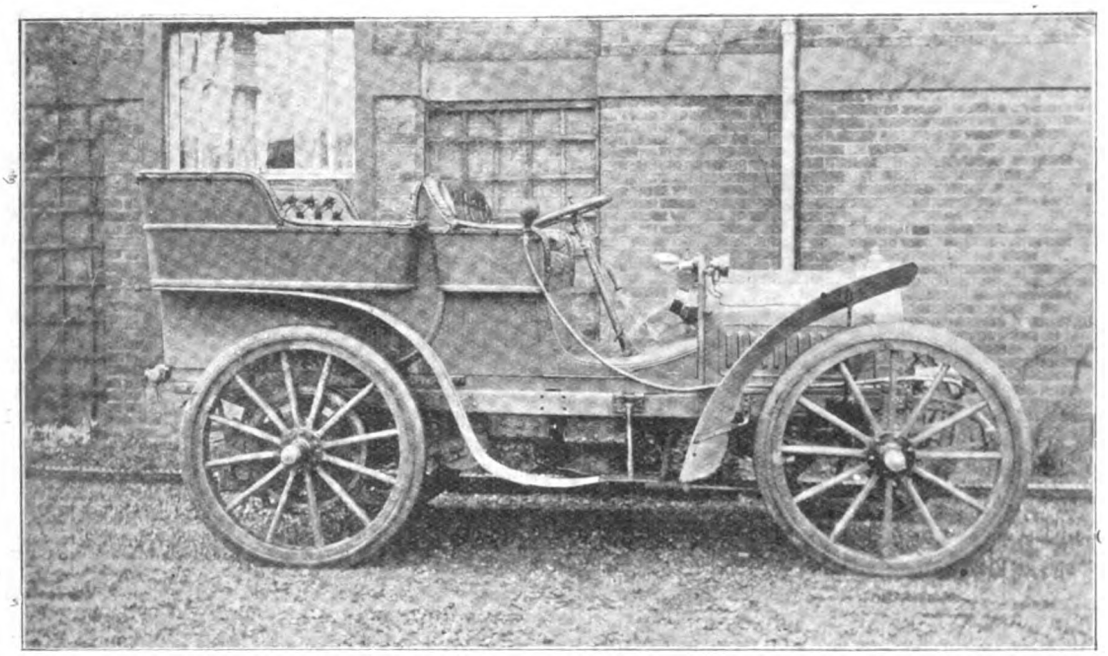
## ELECTRIC MOTORCARS.

Among those cars which were to be seen at the recent automobile exhibitions, and which we briefly described last week, were those of the Electromobile Company, and the Dynamobile exhibited by Messrs. Kuettner, MacDonnell, and Cookson, Limited. The electromobile cars are already very well known, but they have been further improved in detail and possess characteristic features. The frame of the chassis is of pressed steel with rolled-steel transverse members, it is straight in elevation and rectangular in plan, and the long semi-elliptic laminated springs upon which the vehicle is carried ensure easy travelling.

A single motor, rated at 8 b.h.p. at 1,500 revolutions per minute, is carried upon the fixed tubular housing of the rear live axle, and at the side remote from the axle is spring-suspended to relieve the transmission gear from shocks and to enable the car to be started smoothly. Double-reduction, double helical gearing is used between the motor and the differential gear, and by enclosing the whole of the gearing it can be effectively and copiously lubricated, resulting in silent running and pronounced freedom from wear. The motor is of MM. Contal and Gasnier's design, and is series-wound with two separate commutators connected to two separate armature windings. It is totally enclosed, and is provided with large inspection doors to give access to the commutators and carbon brushes. The latter are of the type successfully adopted by Messrs. Greenwood and Batley for their small motors. The controller is carried at the front of the car below the top line of the frame, and its aluminium framework is bolted to two longitudinal frame angles, which also provide a point of attachment for the steering gear. A sheet metal casing below the controller protects it from road dirt and wet, and it may be readily inspected through a trap-door in the floor boards immediately above it. It provides for a range of speed of from three to fifteen miles per hour for forward running, two electric brakes, and one reverse speed. The handle actuating the controller is conveniently placed immediately below the steering wheel, and operates through a tube concentric with the steering column and through bevel gearing, and an index plate below the handle indicates the controller positions for the different speeds.

The battery box is slung below the centre part of the frame, and this position has been adopted to render the changing of batteries easy and to obtain a low centre of gravity, together with other advantages. The battery consists of 44 Contal cells of the pasted type, weighing about 10cwt., and its capacity is 135 ampere-hours. Arranged as a victoria the capacity is sufficient to propel the car 40 miles, or as a double landaulet 30 miles. Experience has shown that with the particular form of plate used the positive plates have a life of from 12 months, and they are cheap and easily renewed. The cells give a one-hour discharge at 90 amperes, three hours at 45 amperes, five hours at 30 amperes, and 9½ hours at 20 amperes.

The Dynamobile touring car exhibited at the Agricultural Hall did not occupy a prominent position, and was probably missed by many who would have been interested in it. It is a modern example of the combination of petrol engine, dynamo, and motors, and in its design the undesirable features possessed by earlier vehicles of this type have been avoided. In appearance it is similar to the majority of petrol cars, and the two-cylinder Fafnir engine of 12 h.p. is carried on the frame beneath the front bonnet. It drives a four-pole compound-wound generator, and supplies current to two series-wound four-pole motors, spring suspended, and independently driving the rear road wheels through single-reduction gearing. The generator and motors are constructed by Messrs. E H. Geist, of Cologne, and it is claimed that their efficiency is such that 80 per cent. of the horse-power delivered to the generator is delivered to the road wheels. If this claim is not entirely realised, this efficiency of transmission still compares favourably with that obtained with many forms of transmission gear in common use with petrol-propelled cars.



The Dynamobile Light Car.

The engine is governed and the car may be entirely controlled through a single lever operating the controller. The driving of the car is thus rendered as simple as that of the ordinary battery-equipped electric car, for under the conditions of running the engine requires little attention other than occasional adjustment of the ignition lever and attention to lubrication. No cells are required other than those used for the electrical ignition system for the engine, and these are arranged to light the car lamps. They are kept charged by the dynamo, and the necessary periodical removal of the cells from the car necessitated with the petrol-propelled car is avoided. An objection to this type of car has hitherto been their weight, but we understand from Messrs. Kuettner, MacDonnell, and Cookson that the 12-h.p. car with tonneau body, arranged to seat six persons, only weighs one ton. With this satisfactory reduction of weight the great objection to these cars disappears, and the advantages they possess in simplicity of control ought to rapidly advance their use.

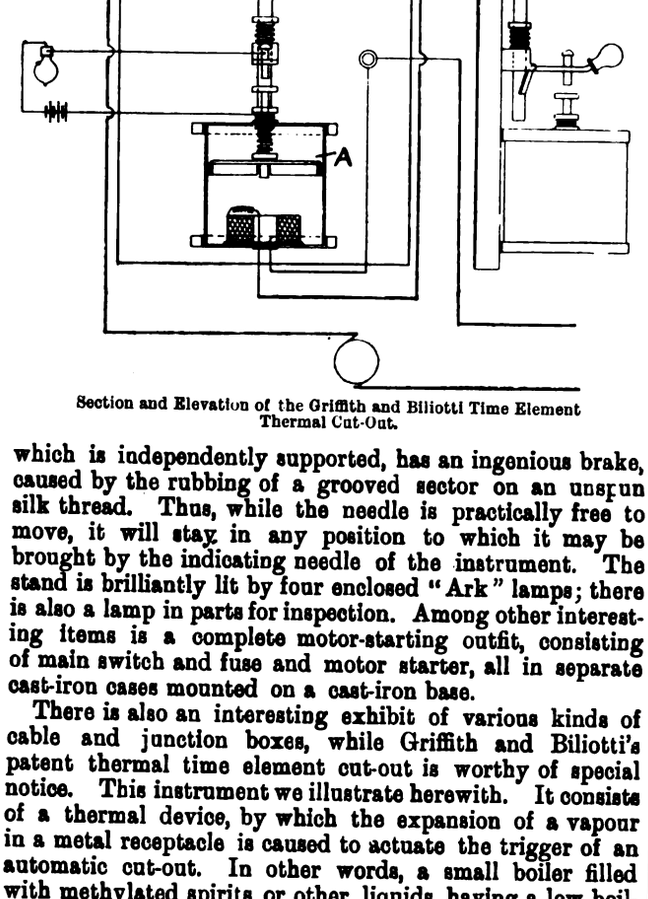
The Dynamobile system has been applied to heavy vehicles, and allows of front driving without in any way

Digitized by Google

complicating the steering gear. We hope to have more particulars of their application for industrial purposes and some results of their performance later.

## HOLBORN AND FINSBURY ELECTRICAL EXHIBITION.

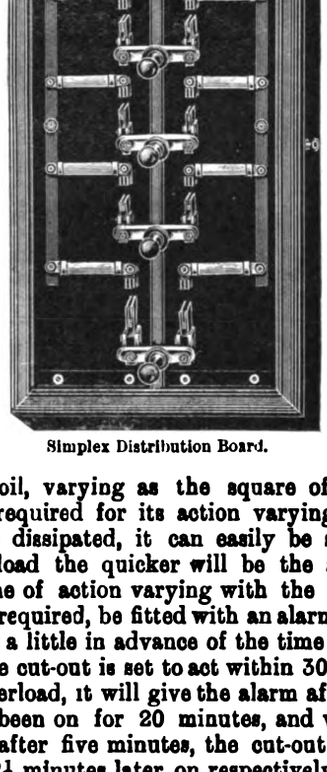
Amongst the stallholders at this exhibition are Messrs. Johnson and Phillips, who, on Stand No 36, have an attractive exhibit of switchboard and portable ammeters and voltmeters of various ranges and types, including hot-wire maximum demand, recording, illuminated dial station type of round and sector pattern, hot-wire and moving-coil instruments, vertical and horizontal edgwise moving-coil, electromagnetic air-damped instruments, portable moving-coil voltmeters of three and four ranges, portable electro-magnetic instruments, portable hot-wire ammeters and voltmeters, pocket instruments. The hot-wire maximum demand instruments are especially interesting, as they afford the means of recording the maximum reading either of the voltage or current, as the case may be. In order to do this a second needle is added, which is carried forward by the indicating needle of the instrument. This second needle,



Section and Elevation of the Griffith and Biliotti Time Element Thermal Cut-Out.

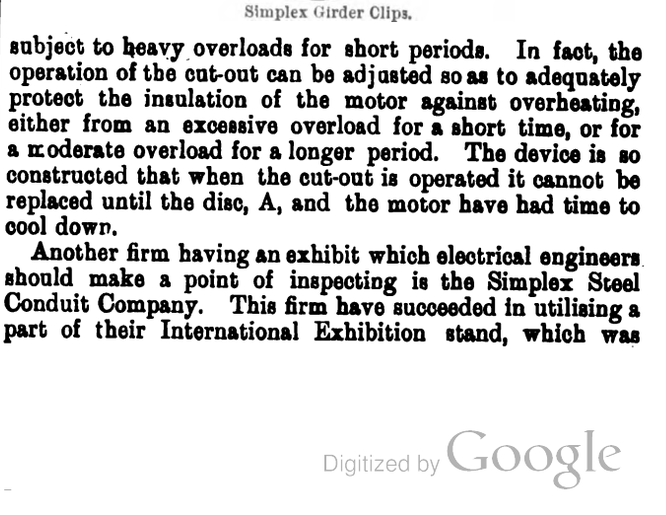
which is independently supported, has an ingenious brake, caused by the rubbing of a grooved sector on an unspun silk thread. Thus, while the needle is practically free to move, it will stay in any position to which it may be brought by the indicating needle of the instrument. The stand is brilliantly lit by four enclosed "Ark" lamps; there is also a lamp in parts for inspection. Among other interesting items is a complete motor-starting outfit, consisting of main switch and fuse and motor starter, all in separate cast-iron cases mounted on a cast-iron base.

There is also an interesting exhibit of various kinds of cable and junction boxes, while Griffith and Biliotti's patent thermal time element cut-out is worthy of special notice. This instrument we illustrate herewith. It consists of a thermal device, by which the expansion of a vapour in a metal receptacle is caused to actuate the trigger of an automatic cut-out. In other words, a small boiler filled with methylated spirits or other liquids having a low boiling point, is used to give a considerable mechanical motion when a definite temperature is exceeded. In the instruments we inspected this boiler is a hollow disc, marked A, made out of two very thin corrugated steel plates. The source of heat is a coil placed below the disc, and connected in series with the motor or circuit to be protected. With normal current the heat given out by this coil is not sufficient to vaporise the liquid within the disc above it. If, however, the current is increased this liquid begins to vaporise, but there is a definite amount of work to be done before the disc expands sufficiently to operate the cut-out. Thus with normal current the cut-out is not affected, but with, say, 25 per cent. overload, it could be so adjusted as to act within a range of 20 minutes to one hour; thus adjusted, an overload of 50 per cent. will bring it into action within 7 to 20 minutes. The watts



Simplex Distribution Board.

lost in the coil, varying as the square of the current and the time required for its action varying inversely as the watts thus dissipated, it can easily be seen that the larger the overload the quicker will be the action of the cut-out, the time of action varying with the overload. It can also, when required, be fitted with an alarm or indicator, which will ring a little in advance of the time of action; if, for instance, the cut-out is set to act within 30 minutes with 50 per cent. overload, it will give the alarm after the excess of current has been on for 20 minutes, and with 100 per cent. overload after five minutes, the cut-out coming into action 10 and 2½ minutes later on respectively, thus giving sufficient notice to the engineer-in-charge to prevent a failure in the supply. The apparatus is an exceeding simple one, and it serves to protect motor circuits which are



Simplex Girder Clips.

subject to heavy overloads for short periods. In fact, the operation of the cut-out can be adjusted so as to adequately protect the insulation of the motor against overheating, either from an excessive overload for a short time, or for a moderate overload for a longer period. The device is so constructed that when the cut-out is operated it cannot be replaced until the disc, A, and the motor have had time to cool down.

Another firm having an exhibit which electrical engineers should make a point of inspecting is the Simplex Steel Conduit Company. This firm have succeeded in utilising a part of their International Exhibition stand, which was

Digitized by Google

used for the Paris Exhibition in 1900. It is built up of a rectangular framework of the company's tubes and conduits, with a liberal interspersion of standard fittings. Sample boards on the stand show the six grades of Simplex conduits in both the enamelled and galvanised types, and the more common types of fittings, such as bends, tees, junction boxes, etc., comprising the most up-to-date of wiring protection systems. Many new features and improvements which have been introduced into the system are shown on the table in front, such as multiple switch boxes, adaptable boxes, watertight fittings, main switches and cut-outs, and distribution boards for use on circuits up to 25 amperes capacity. The illustration herewith shows one of these boards as recently constructed for a special order. The firm have also on exhibit the Simplex girder clips, which have been designed in response to many enquiries for a ready means of carrying conduits on steel girders of standard dimensions. No drilling of the girder is necessary; they are fixed instantaneously by the most unskilled labour. They are supplied in three patterns for girders having up to 6in. flanges (1) for carrying conduits parallel to the girder, (2) for fixing the conduits across the girder, (3) or provided with a special wood base block for attaching ceiling rose, etc. Each of these three types may be obtained either with a hooked clip fitted with a movable nut or left straight for bending over the girder flange.

Messrs. B. Weaver and Co., of 22, Rosoman-street, Clerkenwell, E.C, are showing at stand No. 45 a large variety of moulded "ebonestos" insulators, bobbins, bushes, screwed nipples, hand-wheels, etc. This material has now been on the market for five years, and has proved beyond doubt that it is a reliable insulator of great mechanical strength and high resistance. We also notice that it takes a beautiful finish.

## IMPERIAL NOTES.

### CANADA.

There appears to be a growing tendency in some parts of our Empire to resent the term "Colonial." It is a feeling which it would not be well to ignore, especially as it is the natural outcome of an ambition deserving of our admiration and encouragement. We have Canada more particularly in mind—that country for which the mother land has done much in the past, but whose modern development is due almost entirely to enterprise and push from within. Shall we, then, ignore that pride to which such strength is entitled? No! It is far from our wish to offend the susceptibilities of our kindred across the seas by the use of a word which may be construed to mean something more than is intended. All who have given the matter thought must recognise that in the natural course of things Canada is destined to surpass this little island in those attributes which are the making of a great nation. The development of the country's vast resources of mineral and other wealth is bound to bring about this consummation sooner or later. Nor is it with jealous feelings that we regard the prospect. The old country is not quite played out yet, but its rate of progress, in a relative sense, must diminish as time advances. It requires but a superficial comparison of the potential wealth possessed by the two countries to settle any doubt on this score. But if, by mutual arrangement, we can strengthen the bonds which hold the separate parts of our glorious Empire together, then increased prosperity of any one part will add to the welfare of the whole, making it immaterial whether the condition of maximum prosperity be at one point or another. That, in brief, is our idea of Imperial policy—an empire to be upheld for mutual benefit within its area. Unity is strength, but it must be founded on something more than sentiment. Mr. Chamberlain has indicated a way, but the time when something tangible shall have been accomplished towards the practical realisation of his scheme is not yet, and while political parties are splitting hairs at home the leeway to be made up is increasing.

Apart, however, from politics we are not at all satisfied that manufacturers in this country are sufficiently alive to what might be accomplished by independent efforts in the way of promoting trade between this country and distant parts of the Empire. We hear the same complaint from several quarters—namely, that England fails to recognise the importance of her dependencies and their rising industries, while, at the same time, there is a gross lack of enterprise shown—even to the neglect of sending catalogues.

Thus a correspondent writes from Ontario: "We know very little about English electrical machinery or apparatus—seldom see a circular or catalogue—while our neighbours across the line are actually flooding our country with their literature. Fully 75 per cent. of the advertising matter that I get through the post is from the United States, and the remainder from home manufacturers, excepting occasionally something comes from the old country. This country offers a splendid field for electrical enterprises, being blessed with so much water power, especially in the provinces of Ontario, Quebec, and British Columbia. Millions of dollars are being spent at the present time in developing this power. We in Ontario are obliged to purchase all our coal from the United States, and pay 53 cents a ton (2,000lbs.) duty, having freight bills besides. This is forcing us to resort to the water power as a substitute. One of the largest enterprises of this character going on at present is at Niagara Falls, where over 350,000 h.p. is being developed. Our manufactured electrical goods cost more than they should, especially such lines as glassware shades, porcelain goods, fittings, and other small electric supplies. Electrical instruments and some lines of machinery are also sold at too high a profit. Copper, for instance, is mined on the north shore of Lake Superior and sold to United States manufacturers, who sell to their customers at three to four cents a pound less than our manufacturers will sell to us, just because there is not sufficient competition to hold down our home market to a reasonable profit. *If we had free trade with Great Britain, such things could not be.* I only hope that your people will soon begin to see the great advantage of having free trade within the 'British Empire,' and a tariff wall against all countries who raise a tariff wall against us. If your manufacturers pushed business a little harder here, it might have the desired effect."

Another correspondent writes from the same province as follows: "Canada is going ahead in leaps and bounds. There will be more acres ploughed in the next year, for the first time, in the North-West than are in Great Britain, counting farming land, mountains, lakes, game preserves, and all. England doesn't get the benefit. The smart Yankees, the Germans, and Italians are doing the business outside of cotton, woollen, and silk manufactures. Electricity is the great motive power on the increase. This country could nearly do without coal on account of the possibilities of the many great waterfalls. We can raise the wheat for the world. Our mines are proving to be as extensive as those of the U.S A. In fact, Uncle Sam has to get his nickel from us to even make his battleships. We have no mixed races to deal with. No false religion to stamp out. No sins to answer for unless it be for those of our parents. You Englishmen are too slow. It takes too long to get at the thing. You have done business in China, India, and Egypt too long to get the pace of Western life.

"How it shames one to see 'Henry Boker' or 'Made in Germany' on every piece of cutlery used! Americans are establishing branches in every line and spending millions while Englishmen sit idly by and see the country that has cost the old land so many years of care and treasure exploited by their more enterprising cousins. We put Italy into the rival class, because Italian machinery is being sold here by the ship load, simply because their engineers are making the best waterwheels in existence.

"All Canadians love the mother country and honour King Edward as much as any people could love a wise king, but Canada will have forgotten its relation to England in 25 years unless England gets better acquainted on this side of the Atlantic."

Strong aversion to the term "Colonial" is also expressed in this last letter, but we have already dealt with that matter, and it needs no further comment here. Our correspondent's observations are, no doubt, true enough in the

Digitized by Google

main, but he does not always make those allowances which circumstances justify. For instance, Switzerland and Italy may be regarded as the homes of the water-turbine industry, due to the local demand which promoted its development long before Canada's need arose. In England, on the other hand, the abundance of cheap fuel caused neglect even of the little water power available; hence the particular industry in question received no great stimulating influence, and for a long time progressed only within narrow limits. That the growing demand outside these islands has not been quite lost sight of is evidenced, however, by some notable hydro-plant manufactured by Messrs. Gunther and Sons, of Oldham, for India. Let us hope this beginning is an indication of the rapid development of this branch of engineering.

For the rest we think it is due to Messrs. Dick, Kerr, and Co., Limited, Messrs. Bruce Peebles and Co., Limited, the Electric Construction Company, Limited, and a few other home firms in a minor degree, to say they, at least, have shown what can be done in Canada. But, then, one swallow does not make a summer—nor do a few. Hence it remains for others to follow good examples, instead of bewailing the effects of bad trade.

## ADMINISTRATIVE COUNTY OF LONDON AND DISTRICT ELECTRIC POWER BILL.

*(Continued from page 413.)*

On Wednesday, March 22, before the Select Committee of the House of Lords more evidence with respect to the above Bill was heard.

Mr. C. H. MERZ, under cross-examination, said that while they sought powers to manufacture gas, they had no intention or desire to distribute it in competition with the existing gas companies. He was quite prepared to stand by his figures, and to supply the Hackney Borough Council on terms which would be beneficial to the power consumer and possibly enable the price for light to be reduced. They had written to the Hackney Council on the subject, but had not received any reply.

Re-examined by Mr. Fitzgerald, Mr. Merz said that the average size of the user on the Tyne was about 60 h.p., as against 50 h.p. as assumed for London in the tables. The average was low because while a few large manufacturers took 2,000 h.p., they also supplied the small user. With respect to the figure of 1d. per unit charged by the St. Pancras undertaking, his calculation showed that the actual cost of production for power in this borough was 1·65d. with a load factor of 35 per cent. This being so, the consumers were supplied at a loss. The offer of the Metropolitan Company for the supply in bulk to the St. Marylebone Council was as follows: a sliding scale of 3d. for the first two hours of maximum demand and ¾d. per unit afterwards, with the maximum charge of 1·7d. per unit for the bulk supply. The result was that the St. Marylebone Council had to put up a generating station rather than pay these heavy rates. With the prices under the Bill they would have been supplied in bulk at about one-half of what the Metropolitan Company offered.

The Hon. C. A. PARSONS, under examination, said that with the increase in the size of a steam turbo-alternator the cost per kilowatt decreased. This held good for all sizes up to 10,000 kw. For instance, a 1,000-kw. would cost about twice as much per kilowatt as a turbine of 10,000 kw. capacity. Besides this the larger turbine would consume about 50 per cent. less coal per kilowatt. It would also economise in floor space and in first cost. Models were shown of three sizes of turbines to illustrate their relative dimensions, and to explain how the cost of buildings and foundations did not increase proportionately with the size of the unit. The present supply in the area in question was from 61 generating stations, and the average size of the engine was 500 h.p. This entailed a great waste of capital and in running expenses. The fuel alone would cost nearly three times more than with the unit he suggested. He estimated a 10,000-kw. turbine would have a steam consumption of 13lb. per kilowatt-hour working with 200deg. superheat. The consumption of the Newcastle turbines in the Tyneside Company's station was 15·4lb. per kilowatt-hour. The 18 per cent. difference between these figures would largely compensate for the increased cost of coal in London. He concluded that the average difference in coal consumption when using cooling towers for condensing and when a plentiful supply of circulating water was available, was about 20 per cent. With the cooling towers an enormous weight of vapour was discharged into the air. There had been a marked reduction of smoke on the Tyne since the introduction of the electric power company's system.

Under cross-examination, Mr. Parsons said that with the large unit he proposed there was not the same falling off of efficiency at light loads as with small units. He had built two turbines for overloads of from 6,000 kw. to 7,000 kw., and other makers of turbines had turned out 5,000-kw. sets. With these large units it was quite easy to arrange for 100 per cent. overload. He was not aware that the 1,000-kw. turbine supplied by his firm to the borough of St. Pancras had a steam consumption at full load of 18,000lb., as against 17,000 per hour guaranteed. The figures were new to him, and he stood by his estimated steam consumption for the 10,000-kw. sets. Under re-examination, Mr. Parsons said that the St. Pancras turbine had not yet been supplied with its proper condensing plant, and that no official trials on the set had been made.

Mr. C. E. L. BROWN, of Messrs. Brown-Boveri, of Baden, agreed with Mr. Parsons's evidence. He had had five years' experience in building turbines, and had supplied 10 sets of 7,000 kw. to Basle. His estimate of the cost of a station of the size proposed by Mr. Merz averaged between £7 and £7. 10s. per kilowatt. With turbines it was absolutely essential that there should be a high vacuum, which involved a plentiful supply of cooling water. If cooling towers were used, the vacuum was not so satisfactory, more boiler plant was needed, and the cooling towers required very large ground space. Under cross-examination, Mr. Brown said that the cost per kilowatt of a 3,000-kw. set was about 30 or 40 per cent. higher than with a 10,000-kw. set. In Switzerland the power from the station was frequently distributed by overhead mains.

Mr. S. Z. DE FERRANTI said he had gone carefully through Mr. Merz's estimates, and agreed thoroughly with them. He had looked particularly into the cost of laying the extra high-tension mains, and endorsed the evidence given by Mr. Merz on that subject. He had actually been over 100 miles of streets in London in connection with the scheme. The maintenance charges on these high-tension cables were now well known, as their life had been proved to be long. He had from the first advocated the concentration of large powers into a central station for distribution over a considerable area. He pointed out the disadvantages under which a large number of the existing supply stations suffered, either from difficulties of coal delivery or from want of sufficient condensing water. He considered that the present undertakings could not individually or collectively carry out such a supply as was proposed under the Bill. The stations did not work on the same systems, and hence could not be coupled together into one general scheme.

Under cross-examination Mr. Ferranti said that in the earlier Power Bills the large towns were not included. Last year, however, Bristol was included in the Somerset Power Bill. He did not consider that one could find a precedent for London's needs anywhere else. Also he did not consider that two large power undertakings could be work on similar lines in the same district, but two companies might supply individual consumers in the same district, as had been done in London. He thought the end of the matter would be that the present undertakers would find it advantageous to take bulk supply and become distributors only. An Ordnance map of London showed that the same had happened with the gas industry. There were on the map a large number of gasworks which had ceased to exist. In the same way with electricity, he thought that the present stations would be turned into distributing centres. If this were so, the monopoly which the power company would have would only be a monopoly

Digitized by Google

of cheapness. Under re-examination, Mr. Ferranti said that the unsatisfactory state of some of the earlier power companies might be due to the exclusion from their areas of large towns.

On Thursday, March 23, Mr. VINCENT RAVEN, chief assistant mechanical engineer of the North-Eastern Railway Company, gave evidence in support of the Bill, as affording advantages to railway companies, and described the relations between his company and the Tyneside Power Company in connection with the supply of electricity. Before entering into the existing agreement his directors had considered the advisability of erecting their own generating station. The capital cost of such a station had decided them to take supply from the power company. The supply had been satisfactory. Power was now taken for driving the company's workshops, and arrangements were in progress for the supply of electric energy for plant in the railway company's docks.

Cross-examined, he said he knew of no other railway company other than the North-Eastern, either in England, on the Continent, or in America, which took electrical energy from a company or a local authority. He was aware that the electric railway companies in London supplied themselves already with electric power, but he was sure the North-Eastern Company could not have worked its electric trains so cheaply in that way.

Mr. J. F. S. GOODAY, general manager of the Great Eastern Railway Company, said that that company carried a larger suburban traffic than any other railway in the United Kingdom. His company had been considering the question of electrifying the suburban lines, and their electrical engineer estimated that if that were done they would require about 30,000 h.p. At present no company could give them that power, but they would like the option of taking the supply from a company. There was considerable interchange of traffic between London suburban lines, and if they were electrified it would be advantageous to have electricity supplied to them on a uniform system. He would rather have one substantial company to deal with than a number of undesirable companies.

Mr. BERRY, general manager of the Great Northern Railway, gave similar evidence.

Mr. CUNNINGHAM, general manager of the Central London Railway, said that if such a company as it was now proposed to form had been in existence when the twopenny tube was constructed, the company would have considered taking power from them instead of building their own generating stations.

Representatives of various manufacturing firms were afterwards called to give evidence in stpport of the Bill.

The Committee adjourned until Monday.

On Monday, March 27, Sir ALEXANDER BINNIE, formerly chief engineer to the London County Council, was called as a witness with reference to the proposal to lay a ring main around London. He said he regarded this suggestion as the best possible, and one which would minimise the breaking up of the streets. It was assumed that the tendency of manufacturers desiring to use electrical power would be to remove their works outwards to the "ring." His experience in reference to the electrification of the underground railways had shown the advantage of concentration in producing electrical power. In answering questions put in cross-examination, witness said it was true that the promoters could only supply electricity in the City through authorised distributors. He did not agree, however, that all their cables should be excluded from the City. It was only proposed to lay one main in the City, and that was a cross main from north to south, connecting the two sides of the ring main. Continuing, Sir Alexander Binnie said he knew that the generating station which the Underground Electric Railway, Limited, had erected at Chelsea cost over £1,000,000 sterling, and had a capacity of 67,000 kw., but he did not know that that worked out at a much higher figure per kilowatt than the estimate of Mr. Merz. Re-examined, he said the conduits for the ring main would be laid once for all, and any additional cable would be threaded through it without breaking up the streets.

Mr. A. STENNING, surveyor, said the estimates for land were ample for the requirements. By the clause for exemption from the London Building Acts the promoters desired to be placed in the same category with gas and railway companies. The buildings would be constructed of iron, would be incombustible, and fairly well isolated, and the ordinary rules for prevention of danger from fire would not be necessary.

Mr. C. H. MERZ, recalled, explained on the plans the proposed position of the ring main and the object with which the district had been divided into industrial and non-industrial areas. Westwards from the dividing line the promoters considered there would not be the demand for power for manufacturing purposes to justify them asking for the powers they wished to have in the eastern area, where factories were numerous, and the tendency was towards their increase. The line under the City was for the purpose of connecting the two sides of the ring, and the route might be varied to meet the wishes of the Corporation, but he was not prepared to avoid the City altogether. In the event of the Bills passing, the industrial area would be developed first.

This closed the case for the promoters.

Mr. NEVILLE, K.C., then addressed the Committee on behalf of the nine electrical companies petitioning against the Bill. These companies had embarked very large capital in undertakings carried on on the faith of provisional orders conferring power upon them. Capital to the amount of eight millions sterling had been expended, and a considerable amount of unissued capital would in the ordinary course be used for extensions of works. It was not his contention that no competition should be allowed, but the competition now threatened was not in any sense contemplated when the Act of 1888 was passed. With the provisional orders under which the existing companies exercised their powers were conditions as to purchase from which the promoters asked to be exempt, and without regard to the expenditure of capital in the past the present shareholders were to be deprived of the profits they might naturally expect after the use of electricity as a power had become established. There had been no lack of energy on the part of companies. Up to the present they had paid an average of 4 per cent. to their shareholders, and now, when the outlook was improving, the promoters wished to step in and reap the benefit of past efforts. The promoters anticipated that the existing companies would ultimately abandon their generating stations under the pressure of the cheap supply offered, but when that happened there would be in possession of the field a huge trust with a monopoly of the electrical supply for London in its hands, and then, he feared, no more would be heard of a supply at 0·75d. per unit.

Mr. CONACHER, general manager of the Metropolitan Electric Supply Company, considered that the existing companies had done their utmost to stimulate the use of electricity for power purposes, and their efforts represented in the aggregate a supply equal to 35,151 h.p. Their plant in existence was far beyond that required to meet present needs, and would supply all new requirements arising in the immediate future.

On Thursday, March 28, Mr. Conacher gave details as to the land owned by the companies available for extension to show that there was no need for a new company to supply electrical energy in London. The Metropolitan Company in 1897 purchased land at Willesden for the purpose of carrying out a policy of concentration, and they had in recent years been able to effect remarkable reductions in the cost of supply. The company were following the policy of abolishing their minor stations, and in a few years could give a still cheaper supply. He held that as the power demands increased they could still further reduce their charges. They could produce power then quite as cheaply as the proposed company. According to his reading of the clauses in the Bill, the new company would be enabled to pick up and choose their customers. The Bill would induce inequality of supply. As he read Clause 65, it would allow competition in the supply of electricity for lighting Government departments.

Under cross-examination, Mr. Conacher said his company charged slightly lower rates in those areas where

Digitized by Google

there was competition than in other areas where there was none. With the exception of the London County Council tramways, he could point to no railways, docks, or waterworks supplied by the existing companies.

Mr. L. H. HORDERN, manager of the Westminster Electric Supply Company, said that 13 per cent. of their output was for power, and they had five consumers taking between 100,000 and 200,000 units per annum. Their charge for hotels was 2d. per unit, for tube station lighting 1d., and they were supplying local authorities at 1·1d. per unit for street-lighting. Under the Bill his company would lose consumers taking 2,000,000 units per annum. This would result in an increased cost in supply to small lighting consumers.

On Wednesday, March 28, Mr. L. H. Hordern maintained that his company could supply electricity for power purposes at as low a rate as that promised by the promoters. His company were in negotiation for the supply of 150 h.p. to the Army Clothing Department at Pimlico, and also with the London, Brighton, and South Coast Railway Company for a power supply for lifts at Victoria Station. By their arrangements with the Central Company they could meet all demands.

Mr. A. S. BAIN, managing director to the London Electric Supply Corporation, said under a three years' agreement with the London County Council, the company last year supplied 6,000,000 units for tramway traction. As the output doubled, the price went down by one-half. Negotiations were proceeding for supplying many large undertakings at $\frac{3}{4}$d. per unit for power purposes. They had now 12 active competitors within their area. If the promoters obtained their Bill they might, under Clause 69, exercise a power other companies had not, to enter into a combination with another company in the area, and, with the assistance of capitalists, sell below cost of production until they crushed out competition, and then they would have an absolute monopoly.

Prof. A. B. W. KENNEDY gave his opinion that the Westminster Company could meet all demands likely to arise, and that the capacity of their modern plant was sufficient.

Mr. H. W. SPRUNT, manager for the South London Electric Supply Company, said that, exclusive of a temporary supply to the London County Council tramways, they sold last year 274,000 units for power purposes.

Major CARDEW urged that, as the existing companies were able and willing to meet all prospective demands for electrical power, they should not be subjected to further competition during their tenure of their powers.

Mr. SEALE, manager to the Charing Cross Electric Supply Company, said they had offered to supply the local authorities at $\frac{15}{16}$d. per unit.

Colonel CROMPTON gave evidence in which he questioned the accuracy of the promoters' estimate.

## APPLICATION OF ELECTRICITY TO INDUSTRIAL PURPOSES.*

BY J. F. C. SNELL, M.I.C.E., MEMBER.

Many papers have been read during the last few years on this subject, and the author feels some diffidence in further discussing it. Yet, owing to the increasing use of electricity as an agent in the transmission of energy, and in its application to the driving of machines in shipyards, engine works, collieries, etc., he may be excused for still further discussing so important an agent, which is so extensively used by members of this institution. For there are at least two very important points which have to be dealt with constantly, in this district especially, and upon which there is still a great divergence of opinion. These are as follows: (1) The comparative economy between installations (for the driving of machine tools) laid down at the works themselves, and the purchase of electricity from an outside power station owned by either a separate company or by the municipality; (2) the comparative advantages of direct current and alternating polyphase currents. (As the subject will be treated with particular reference to the North-East Coast, only three-phase alternating currents will be considered.) Further, the author wishes to make clear two other matters which are of great importance to the management of these works: (3) their position electrically with respect to the Board of Trade and the Home Office; (4) the importance and economy of standardisation.

The author, as a member of the Engineering Standards Committee now deliberating in London, may be excused for driving home this necessity for standardisation, both in the interest of users and manufacturers and of the electrical and other industries adopting electricity for the transmission of power. Thus it is hoped that a clear understanding will be arrived at as to the relation of independent electrical generating plant *versus* the purchase from a public source of supply. The author, though himself the servant of a municipality engaged in the supply of electricity for general purposes, including most important industries, will endeavour in this paper to hold himself entirely free from bias, and to give a plain unvarnished account of both sides of this question, whichever view may be supported by the actual results about to be given, and he hopes that a clear conception of the obligation of users and suppliers to the Government departments for the protection of employés and property may be obtained; and also that useful and standard data may be recorded for future application by works now adopting electrical driving, and which will, undoubtedly, be driven by this method in the future.

### 1. RELATIVE ADVANTAGES AND COSTS OF INDEPENDENT AND CO-OPERATIVE GENERATION OF CURRENT.

Through the kindness of certain distinguished members of this institution, the author is able to record the actual results of electrical stations owned by two large shipyards, one of which is being partly driven by its own steam-driven plant and partly from a town supply, these two systems being entirely separate from one another. The other example is that of a shipyard supplied from its own gas-engine-driven generating plant. In the first case, the following particulars are necessary for a proper criticism to be given of the results—viz.: 4 boilers (marine type), 160lb. pressure; no superheat. 4 engines, each 250 h.p.; 1,000 total horse-power; 300 revolutions per minute, triple expansion, condensing. 4 dynamos, each 168 kw.; 672 total kilowatts, direct coupled to engine, compound wound, direct current, 220 to 240 volts. 104 motors supplied; 1,895 total horse-power; motors varying from 1 h.p. to 40 h.p. Class of work, combined shipyard and engine works. Maximum load observed, 504 kw. Total units generated per annum, 891,655. Load factor, 22 per cent. Class of coal used, smalls, 11s. per ton. Lbs. of coal per unit generated, 7·3.

*Note.*—It is only fair to add that owing to adverse local conditions the average vacuum is only 15in. The total capital outlay on this generating plant is £17,184, and the following were the working costs for 12 months—viz.:

| | | | |
|---|---|---|---|
| Labour (including 20 per cent. for working charges) | £832 | 14 | 1 |
| Coal, 2,924 tons at 11s. per ton | 1,608 | 11 | 11 |
| Feed water at 8d. per 1,000 gallons | 59 | 0 | 6 |
| Circulating water—make-up | 31 | 19 | 6 |
| Oil | 58 | 8 | 5 |
| Repairs and general stores | 141 | 2 | 10 |
| Works costs | £2,731 | 17 | 3 |
| Depreciation at 5 per cent. | 571 | 13 | 2 |
| Interest, 4 per cent. | 457 | 6 | 8 |
| Rent, rates and taxes, taken at 33 per cent. on the item for labour | 249 | 16 | 2 |
| Total costs | £4,010 | 12 | 9 |

thus making a total cost per unit of 1·08d. The second example is as follows: Number of gas-engines, 3. Total brake horse-power, 360. Dynamos, 3. Total kilowatts, 225. Belt-driven, shunt-wound, direct-current, 230 volts. Number of motors, 34. Total horse-power, 397 (motors vary from 3½ h.p. to 44 h.p. each). Class of work, shipyard. Maximum load observed, 207 kw. Total units generated during four months, 83,125. Load factor, 14 per cent. Cost of gas, 1s. 6d. per 1,000 cubic feet. During these four months the following were the ascertained

* Paper read before the North-East Coast Institute of Engineers and Shipbuilders on Feb. 24.

Digitized by Google

costs: Number of units generated during the four months' test = 83,395.

| | | | |
|---|---|---|---|
| Town gas, 3,000,828 cubic feet at 1s. 6d. per 1,000 feet ... | £225 | 0 | 10 |
| Engine and dynamo oil ..... | 24 | 1 | 7 |
| Waste and stores..... | 5 | 9 | 10 |
| Repairs..... | 5 | 16 | 8 |
| Water ..... | 2 | 0 | 0 |
| Labour ..... | 84 | 12 | 1 |
| Interest and depreciation ..... | 60 | 0 | 0 |
| | £407 | 1 | 0 |

N.B.—No account allowed for supervision, or general establishment charges, or rating of machinery.

The cost representing 1·173d. per unit.

From these two examples it will be seen that there is a variation in cost per unit from separately driven plant of respectable dimensions from 1·08d. to 1·173d. It is only fair to point out that the average vacuum in the former case is only about 15in., and that the steam-pipe lead is of some length, both of which are factors which must operate against the costs; thus the results would have been better had there been ample circulating water, and a better steam-pipe range, or a moderate degree of superheat. Also, in the latter case, it will be observed that the dynamos are belt-driven, which must account for probably at least 5 per cent. loss of power, which would be saved by direct driving. On the other hand, the plant installed probably represents the cheapest capital expenditure on account of the higher speed of the belt-driven dynamos.

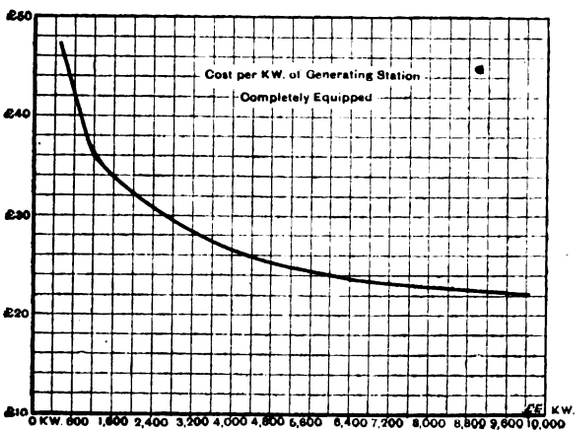


FIG. 1.

The author has always contended that in works requiring from 300,000 to, say, 1,000,000 units per annum, and with a load factor of 20 to 30 per cent., the cost will be found to vary from 1·25d. per unit to 1d., and he is of opinion that, looking at the question broadly, and taking into due account an adequate depreciation of plant and average cost of upkeep for, say, a period of 20 years, 1d. is about the lowest limit for installations of the size stated. He is aware, of course, that there are special cases in which, either through an abnormal and excellent load factor, or through the utilisation of blast-furnace gases, the cost is materially reduced below this figure. These, however, are quite the exceptions, and he affirms without fear of contradiction that the generality of installations will be found to have costs within the limits cited. As to the advantages of the works saving the capital expenditure; the responsibility involved in laying down their own plant, or the loss represented by the valuable space occupied; the incidental losses which result from having the machinery ready during many mornings in the year after holidays without the certainty of the men turning in, or during slack times; and the frequent special arrangements required to be made for working night shifts—all these items, which may be put to the credit of the outside power stations' point of view, will be dealt with later in the paper.

Now let us turn to the other side of the question—viz., supply to works from outside sources. Whether it be a power company like the Tyneside Power Company, or a municipal works such as Sunderland, what will be said will be true of most stations, and may be considered as generally applicable to all. The first and most obvious saving is in the capital outlay per kilowatt. The accompanying curve (Fig. 1) gives the relation of the cost per kilowatt (1 kw. = 1⅓ h.p.) between stations varying from 250 kw. up to 10,000 kw. Many independent plants do not exceed 200 kw. in extent, while the two power stations referred to have actually exceeded or are nearing the higher limit. Now, if, as the diagram shows, the smaller installation cost £45 per kilowatt installed (which figure includes buildings, boilers, engines, steam-pipes, condensers, dynamos, and switchboards completely equipped on the one hand; or buildings and gas-engines, water-tanks, dynamos, and switchboards completely equipped on the other hand; and also includes, for obvious purposes of safety, spare plant representing probably some 50 per cent. of the capacity of the running plant), it is obvious that the 10,000-kw. station, costing about £20 per kilowatt, can afford to spend money outside the station in laying adequate cables and fixing the necessary transforming machinery, and yet be able to effect a considerable saving on the capital sum.

Secondly, it must be equally obvious that, while a decent load factor of anything between 15 and 35 per cent. even may be obtained in an independent installation, yet the combination of a dozen and, *a fortiori*, several dozen such works in one station must result in a far better load factor, which is actually in practice found to be anything from 45 to 55 per cent. This improved load factor at the resultant station is owing to the non-synchronism of the various maximum demands on the several works, which among station engineers is known as the "diversity factor." This diversity factor really has a high value. The author knows examples where the resultant maximum load at a generating station is only some 60 per cent. of the integrated total of the maxima. This, obviously, means that a given amount of plant installed at the power station is able to deal with a much larger total of horse-power of motors installed in various works than the same plant could possibly deal with if it were split up into a number of small independent installations.

As one is speaking to so many engineers who may not be specifically electrical, it would be well to define the term "load factor," as so much depends upon this, the most important detail after capital cost in producing economical results. The load factor of any plant, then, is the ratio of the actual units generated in any given time to the units which would be generated were the plant working continuously at full load during that time. For example, the number of hours in a year is 8,760; an installation representing 100 kw., working continuously for 8,760 hours, would generate 876,000 units. If it is actually found that 219,000 units have been generated during the year, then the load factor of that plant has been $\frac{219{,}000 \times 100}{8{,}760} = 25$ per cent. It must be clear to anyone that a steam dynamo of 100 kw. working continuously will cost less per kilowatt per annum than if only working more or less intermittently, or at varying loads, during a quarter of that time. Now this is another of the advantages claimed for general sources of supply, and is not based on mere hypothesis, but is actually proved from the results obtained—viz, the thereby increased load factor due to the supply given to several works—together with the practical diversity of their maximum loads, as before stated, enables the kilowatt or the horse-power per hour (whichever basis be taken) to be more cheaply produced than if each works produced its own current.

The scale of prices upon which a power station may be reasonably expected to supply current is shown in the accompanying diagram (Fig. 2). This scale is based upon the practical capital cost of a large power station equipped with modern appliances, and the remaining figures of fuel, stores, wages, and other establishment charges are taken from actual practical results. Reference to Fig. 3, which deals with the cost of a small local station installed for the supply of large works, demonstrates at once the influence of the capital cost upon the units generated, and the economy which can be obtained from the concentration of many such small installations in one big power station, and even this does not account for the important detail already referred to—viz., the "diversity factor." From these two diagrams it will be possible for any director of works to see the relative costs for his particular factory

Digitized by Google

which will result from either the town main or his own plant. There are other economic reasons why works should, in most cases, purchase their power rather than instal a separate generating plant—viz, overtime shifts can be arranged without any trouble in the way of keeping

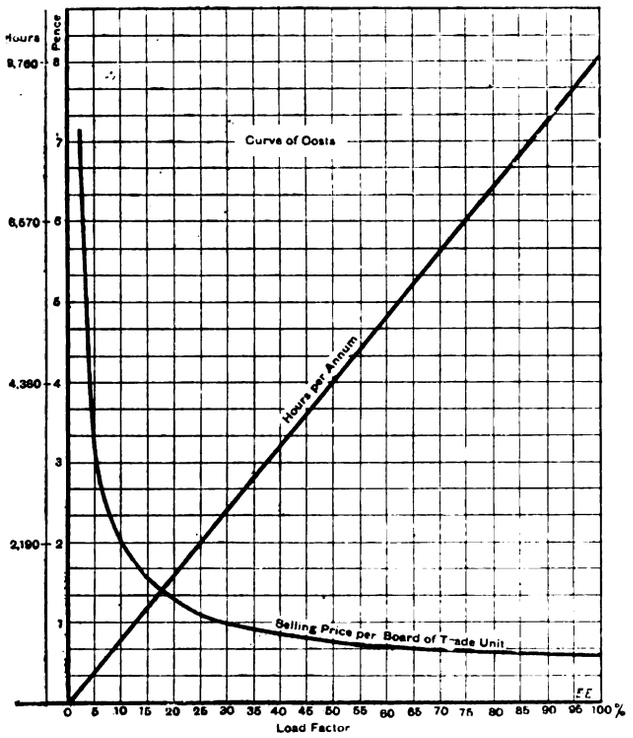

FIG. 2.

special men for working treble shifts in the local power station; on holidays there would be no worry from having to light up boilers or start gas-engines, and having the machinery ready to run and no men turning in; the manufacturer is saved the capital cost of the generating plant, and the space which the generating plant would

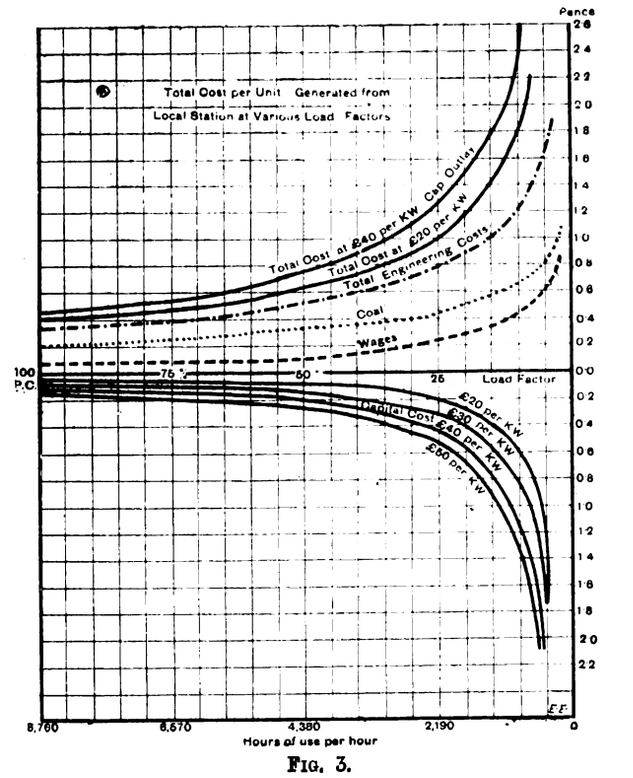

FIG. 3.

occupy has a great value for other purposes; and, further, he has not to trouble himself about antiquation of plant, or more efficient methods of generating electricity in the future. It will be granted that motors which are capable of working from 85 to 95 per cent. efficiency (according to the ratio of their load) will probably not be superseded by any more economical prime mover in the future. On the other hand, the manufacturer is entirely dependent on an outside source of supply—and the transmission cables and transforming machinery introduce a further element of breakdown, which, though amply guarded against as far as skill will allow, *is* a factor which cannot be negligible. It behoves a manufacturer, therefore, to see that in becoming dependent on an outside power or supply station the cables should be duplicated, and an adequate amount of reserve transformers should be insisted upon. From a comparison of the two diagrams (Figs. 2 and 3) one gets the following results for outputs of 100,000 or more units per annum.

| Load factor. Per cent. | Units per kw. demanded. | Price from power supply. Pence. | Price from own local station. Pence. |
|---|---|---|---|
| 15 | 1,314 | 1·5 | 1·75 |
| 20 | 1,752 | 1·25 | 1·45 |
| 25 | 2,190 | 1·125 | 1·25 |
| 30 | 2,628 | 1·00 | 1·10 |
| 35 | 3,066 | 0·875 | 0·95 |
| 40 | 3,504 | 0·800 | 0·90 |
| 50 | 4,380 | 0·75 | 0·75 |
| 60 | 5,256 | 0·68 | 0·65 |
| 70 | 6 132 | 0·65 | 0·58 |
| 80 | 7,008 | 0·62 | 0 60 |

The deductions to be made from the diagrams referred to show that the higher the load factor of a particular installation, the less reason is there for the purchase of power from an outside company, and the more excuse for installing one's own plant; and that at a load factor of 50 per cent. the costs are identical, and that for load factors above 50 per cent. the power can be more economically generated on the spot. But as this only applies to exceptional plants, such as pumping or paper mills working continuously, and does not apply to engine works and shipyards having a load factor of under 40 per cent., the inference is that the greater number of works in this district will benefit from co-operation by becoming consumers of one general power supply.

*(To be continued.)*

## FRICTION LOSSES IN SHAFTING.

The efforts that are being made by the engineers in charge of the large power stations, supplemented by the fact that one modern textile factory—viz, the Heasandord Mill, near Burnley—has been installed with electric motors for driving not only the preparation machinery, but also the actual looms, have caused many millowners in Lancashire to consider the advisability or otherwise of adopting this system for the transmission of power both in spinning mills and weaving sheds.

As might be naturally anticipated, the first question asked by these millowners is, What will the generation of electricity cost us if we instal our own dynamos? and, secondly, What will the current cost us per brake horse-power if we take a supply from the public mains? When this question has been answered to their satisfaction, there arises the equally important question, What shall we save, and if there be an increased economy, will it be of sufficient magnitude to allow ample margin not only for depreciation and interest, but also to justify us in the spending of a large additional capital?

The usual answer that appears to be given by the electrical engineers who are trying to make a speciality of textile work is to refer the millowners to American practice, and to state in glowing terms the great advantages that have been reaped there by enterprising millowners. Unfortunately, this does not appeal to the hard-headed men owning our cotton mills. They attach a certain amount of importance to results obtained in America or on the Continent, but argue that the conditions that obtain here are probably different to those that obtain abroad, and, furthermore, that if this advantage has been obtained in one mill, it should be easy to demonstrate how it has been obtained, and to locate exactly where the saving has been effected. In his paper before the Managers of Textile Mills, Mr. Payne stated that while he knew from his experience that economical results were obtained by adopting electrical driving in all classes of textile mills, he could

Digitized by Google

not definitely locate the exact places where this greater economy was effected; and until this more exact economy information is obtained or until several English mills have been electrically equipped and the economical effects noted in this country, it is doubtful if any great number of mill-owners will be persuaded to make the innovation.

The usual method of procedure in making a survey for the preparation of a scheme for electrical transmission is first of all to find the total power developed, and then to find the amount of power lost in friction, and by deducting this latter from the total power it is assumed that the total useful power is arrived at. This method would be quite satisfactory if only the amount of power lost in friction were obtained, but unfortunately this is not the case, and the figures which are arrived at are at the best only an approximation, and unfortunately there is no reliable data available respecting the losses due to friction in shafting and belting transmission.

To a very great extent the whole of the information respecting friction losses is confined to the results deduced from Prof. Benjamin's experiments, and published by him in the paper read before the American Society of Mechanical Engineers in December, 1896, supplemented by the article in the New York *Machinery* in the following year. While admitting the great value of these papers, and the careful research work conducted by Prof. Benjamin, the writer is not satisfied that the results obtained are correct, though he is thoroughly satisfied that the usual practice of obtaining the frictional losses, which is indicated above, gives results that are only approximations, and at the best not close approximations.

In the first place, the manner of taking steam indicator diagrams is far from satisfactory. The first requirement is that the indicator shall register correctly, while following this it is necessary to take readings of the speed and pressure at the exact instant the cards are taken; after this a calculation has to be made of the area of the piston rod and so forth, so that while the actual cards are not absolutely correct, as is shown by the difference that always exists when repeated or duplicated cards are taken, the amount of the error will probably be exaggerated by the calculations that are afterwards made, and some slight divergence from the true speed or the correct steam pressure.

Granting, however, that the cards obtained are correct, and that the calculations contain no error, the true frictional loss has not been obtained. What is obtained from the first set of cards is the power required to turn the engine and the shafting round *unloaded*. If now a second set of cards are taken with the shafting fully loaded, it is manifestly incorrect to assume that the difference in the power indicated by these cards and the first set is the power usefully employed. This assumes that the frictional loss is a constant for all loads, which it cannot be. The power required to turn a shaft at a certain speed when the load is light is entirely different to the power that is required to turn the same shaft at the same speed, neglecting entirely the power required for the load when the shaft is loaded. So that if by the customary method it is found that the frictional loss amounts to, say, 34 per cent., it is quite reasonable to assume that the true full-load loss is 40 per cent. or perhaps more.

A case under the writer's personal knowledge proves this. A motor was temporarily put down to drive a certain machine, when it was found that the current required was 40 amperes at 200 volts; afterwards the machine was moved so that the motor drove it off a line shaft—that is, instead of the motor driving the machine through a direct belt, two belts were used, and a long length of shafting had to be turned. To drive the belts and the shafting it was found that five amperes at 200 volts were necessary, but to drive the machine under these conditions required not 45 amperes, but 50 amperes. This showed that there was an additional frictional loss of equivalent to 200 volts 5 amperes; but the experiment did not indicate where this loss could be located. It is evident that if the major portion of this loss is in the shafting and belt transmission, there can be no difficulty in showing why a greater saving is the result of the electrification of various factories, because there is a far greater frictional loss in the old system than is generally allowed for.

In the case just mentioned the shafting was a simple long length. Now, every mechanical engineer knows that one of the chief places for loss of power is in bevel gear, and it would be interesting to repeat the experiment driving through a pair of bevel wheels. This would be the more interesting with respect to the installation of electrical driving in spinning mills and weaving sheds, owing to the large number of bevels that are always found in these factories.

There is a large unexplored field for research in connection with frictional losses under different conditions, and the data that would be gleaned would be of the most useful character. It would appear as though the only satisfactory method of carrying out such research is an electrical method. It is generally stated that the greatest difficulty is experienced in obtaining figures relating to frictional losses owing to the fact that tests are made under special and not under normal conditions; the lubrication, for instance, is either better attended to, or other special conditions obtain that affect the result. There is no real reason why this should be the case. All that is required is a dynamo and motor whose efficiencies are known exactly for all loads. If then, long lengths of shafting are driven light off the motor, the input being noted, it is easy to find the actual power required to turn these shafts round light. The dynamos should be then belted to the farthest shaft, and the electrical power generated either used for some useful purpose or dissipated in a water bath. By this means the shaft could be loaded to any desired extent, and tests could be made not only at full load, but also at any intermediate loads. All that is necessary is to note the input of the motor and the output of the dynamo at the same moments, and, in order to prevent error, the measuring instruments could be duplicated, and use also could be made of recording instruments. The efficiencies of the dynamo and motor being known, reliable figures could be obtained. Such a test could be carried out for all forms of shafting transmission, and would have the further advantage that it could be made under normal conditions, and not under special conditions. To be of any commercial value, the tests should be carried out on shafting already erected in different classes of factories, and not on new shafting specially put up for the purpose.

There is no doubt that such a series of tests would be costly, and would occupy a considerable amount of time, but the results would amply repay the capital cost and the labour. Probably there is no individual firm who are in a position to conduct such a series of tests, and even if they did they would probably retain the data for their own use; but considering the large amount of money which is spent annually by different societies and colleges upon research work, much of which is more of a theoretical than a practical value, there should be no difficulty experienced in inducing one of these bodies to make a series of practical tests upon frictional losses.

## INSTITUTION OF ELECTRICAL ENGINEERS.

The following candidates have been elected:

*Member.*—J. McL. Robb, Engineers' Department, Postal Telegraphs, Belfast.

*Associate Members.*—R. G. Cooper, 6, Dogo-street, Canton, Cardiff; E. A. Davies, 124, Croydon-road, Anerley, S.E.; A. Davis, 121-125, Charing Cross-road, W.C.; B. Glenny, 14, Harrington-street, Dublin; R. D. B. Glenny, 14, Harrington-street, Dublin; L. O. Heyes, Lynwood, Park-crescent, Wigan; W. A. Heyes, 5, Sefton-street, Southport; E. O. Hopkins, 32, Kestrel-avenue, Herne Hill, S.E.; E. W. King, Corporation Electricity Works, Bootle; E. H. Rayner, M.A., Elm Lodge, Queen's-road, Teddington; J. W. Wyatt, 31, Benton-road, Sparkbrook, Birmingham.

*Students.*—J. A. Allan, Seafield, Longman-road, Inverness; E. L. Pretrand, 499, King's-road, Chelsea, S.W.; C. F. D. Suggate, 28, Slatelands-road, Glossop.

## APPOINTMENTS VACANT.

**Chief Electrical Engineer,** Bermondsey Borough Council. £425 per annum.

**Tramways Inspector,** Birmingham Corporation. Salary about £4 per week. Applications by April 12. See advertisement.

## ACQUIRING FREEHOLD RIGHTS.

The *Times* in its engineering supplement this week furnishes another proof, if one were needed, as to the rapid development of telephonic work during the last quarter of a century. Its figures relate to America, and are taken from the census reports. They give details for the years 1880 and 1902. In the former year there were 48,414 subscribers, in the latter 2,178,366. At the earlier date the number of employés was 3,338, at the latter 78,752, while the capital authorised was respectively £3,477,340 and £76,906,813, the latter bringing in a revenue of £17,365,107, permitting dividends to the amount of £2,996,543, while a surplus remained of £1,335,609. Roughly speaking, these figures show interest of about 4 per cent. paid, which could have been increased if no other consideration intervened to over 5 per cent. Of course, without far more details than these no valid deductions of any kind can be made. We have given them for only one purpose, to show the increasing importance of the industry. In our own country the importance is as great, but the troubles in the way of telephony are greater, because imperial, municipal, and private enterprises are all mixed up, and will have, within the next few months or years, to be straightened out. A committee will, we presume, be appointed one of these days, and among other problems will have to consider the position arising from the existence of overhead wires over a variety of properties without demur for a period of twenty years. An owner is approached for permission — possibly an agreement is made to pay a nominal yearly rent of a shilling—to erect poles and run wires for telephonic purposes. Very often the owners are not fully alive to the consequences of a more or less informal acquiescence in the procedure. We believe, however, that if the owner is not far-seeing enough to make special terms, get a proper legal agreement, which has to be duly stamped with annuity duty, and be careful to exact the rent annually, he may at the end of a tolerating period of twenty years find that he is no longer master of what may be or what may not be done. The amount being small is probably frequently uncollected, because it seems more trouble than it is worth to collect; but unless the party pays this annual consideration no acknowledgment of the owner's rights is given. Assume that the dealing is with a telephone company. If this shilling remains uncollected year by year till twenty years have passed, and there is no written document on the part of the company, the company will obtain a freehold easement; and then, if the owner requested the removal of posts or wires, he would find that he had legally no power to compel the removal, the answer, legal and effective, being that the company had acquired an easement, and could not be compelled to remove poles or wires. Of course, we have to make a good many assumptions. The Post Office, if it ever takes over the companies' and municipalities' systems, will take what exists at the time of taking over, and will not object to freeholds. So that it behoves owners to look after themselves, as it will not be in the Government's interest to look after them. Undoubtedly a Government office desires in the abstract to deal fairly all round, yet it may object to retrospective action. We wonder how many so to say freeholds have already been created because the trouble to prevent has not seemed at the moment worth the candle. Perhaps it will be argued that overhead wires in this country are doomed, and that in the future everything will be underground. That view may be correct; it is, however, very doubtful. The necessities of town thickly populated, and thinly populated districts, are quite distinct, while the law holds

Digitized by Google

good for both. We are sorry to say that the *Times* of late, instead of discussing certain questions in a spirit of fairness, seems to look upon them with a bias. It is—so are we—anti-municipal, but it always seems to discuss as if the pro-municipalists had not an exceedingly strong case. Above we have pointed out the necessity of care in owners that they lose not their rights. The *Times* in the same issue as it gives the telephonic figures shows the difficulties not only in free competition in matters such as tramways, lighting, and telephony, but even when there is no competition, when it refers to one class of street work interfering adversely with some other street work. All these questions more or less hinge for success upon a common use of the streets. If telephone wires are by-and-by to be wholly underground, more fuel will be added to the fire. If they are to be underground in the hands of monopolists, then the general public have great cause to grumble, for their free use of the streets is continually interfered with, to their loss both in time and money. The forthcoming committee will have its work cut out to do justice between companies, municipalities, the general public, telephone users, and the Government departments.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### COPIES OF CORRESPONDENCE, ETC., *RE* SALE OF SPECIFICATION BY MR. BUCKLEY FOR WORK AT BATLEY CO-OPERATIVE SOCIETY.

*Letter from J H. Taylor and Co, Huddersfield, to H. B. Buckley, architect, Batley, 11-2'05.*

"We enclose herewith cheque value 10s. deposit for specification for above. Please forward this to ——."

*(2) Postcard Mr. Buckley to Messrs. J. H. Taylor and Co., 13 2'05.*

"The 10s. is a charge (not returnable) see advt., and not deposit, so please let me know by return if you require a copy or not. Will reserve you one until hearing from you."

*(3) J. H. Taylor and Co. to Mr. H. B. Buckley, 15-2'05.*

"Your postcard to hand. The advertisement in the *Yorkshire Daily Observer* did not state that the amount paid was not returnable. We have never previously been asked to make a payment of this description, in an experience extending over forty years. We are willing to give you a tender free of charge, which will cost us not less than £2, but we certainly are not prepared to pay for the specification. We shall be pleased to give you a tender on the above conditions. If, however, you do not agree to this, please return our deposit."

*(4) H. B. Buckley to J. H. Taylor and Co., 16-2-'05.*

"Thank you for your letter of the 15th inst. *re* charge of 10s. This has had to be made owing to the great number of applications previously made for the specifications in order to keep out the inferior small firms, and so give the better a fair chance of giving a proper tender for the work."

*(5) H. B. Buckley to Lancashire Electrical Engineering Company, Ashton, 10-2-'05.*

"*Re* wiring for electric lighting for Batley Co-operative Society. Please note the 10s. is a charge, and not a deposit (see advertisement). The specifications are ready. Do you wish to have them? If so, I will forward them on hearing from you."

*(6) H. B. Buckley to Lancashire E.E. Co., 13-2'05.*

"Herewith is returned your cheque as desired. Surely, if you did not desire to conform to the conditions, you might have said so without imposing your opinions on others. Instead of being to the disadvantage of the Co-operative Society, it is intended as the reverse, as probably only the best class of firm will compete for the work, thus eliminating smaller and inferior firms and giving a better chance to the firms who do tender. Evidently you have not considered the matter, otherwise you would have seen this. There have been shoals of persons desirous of tendering for the work which would have been useless, and taken both their's and the committee's time."

*(7) Batley Co-operative Society to Lancashire E.E. Co., 17-2'05.*

"We have your letter *re* charge for specification. We regret if there is any irregularity in this matter. Of course, Mr. Buckley is our architect, and he was asked to prepare specifications and get in tenders for the work, and we were not aware that this course would be adopted. His explanation is that a great many firms apply for specifications, and then he hears no more of it. It has gone too far now for our interference on the present occasion."

*(8) Lancashire E.E. Co. to Batley Co-operative Society, 18-2'05.*

"We thank you for your courteous letter of the 17th inst., and are pleased to know that you were not aware of the course adopted in reference to the specification for lighting. We note that it is now too late for your interference, but we shall be quite satisfied if our action will prevent a similar condition in future tenders. Your architect ought not to send the specification without a deposit, and then he would safeguard himself against bogus people applying. We send herewith for your perusal an original letter showing how the best firms deal with such matters. Kindly return the letter after perusal. Again thanking you for your attention to the matter."

*(9) Leeds E.C.A. to Mr. Buckley, 18-2'05.*

"The members of the Leeds Branch of the Electrical Contractors' Association (Incorporated) desire to express their disapproval of the charge of ten shillings (not returnable) made in connection with the supply of specifications of the electric light installation for the new central stores of the Batley Co-operative Society in Commercial-street, Batley. They wish to point out that this charge is a new departure, quite different to a returnable deposit, and that it does not commend itself to their sense of the fitness of things, and is likely to lead to abuse. They do not, of course, wish to dictate to anyone, but merely to respectfully urge their objection."

*(10) Mr. Buckley to Leeds E.C.A., 21-2-'05.*

"In reply to yours of the 18th inst., I am well aware about the 'new departure' you name, which was done with a purpose, and of a necessity, and the same has answered its intentions."

*(11) Minute of Resolution passed at Meeting of Northern Section E.C.A., 25-2-'05.*

"That this meeting strongly condemns the action of the architect to the Batley Co-perative Society in asking for a money payment (not returnable) for copies of specification for electrical work to be done, and that copies of the correspondence and of this resolution be sent to the Batley Co-operative Society, the Leeds and Yorkshire Architectural Society, and the electrical and architectural Press."

## INSTITUTION OF MECHANICAL ENGINEERS.

The first report of the Steam-Engine Research Committee was presented by Prof. David S. Capper, member, at the meeting of the institution on the 17th inst. The above-mentioned committee was constituted at the instance of the late Mr. Bryan Donkin to investigate and carry out research upon the initial condensation in steam-engine cylinders. Through the kindness of Messrs. Marshall, Sons, and Co., of Gainsborough, a special engine was obtained at cost price for the purposes of the investigation, and erected in the engineering laboratory at King's College. The report deals at considerable length with the results of experiments, extending over several years, on jacketed and unjacketed cylinders. But important as the subject undoubtedly is, we are unable, owing to the great pressure on our space, to give

Digitized by Google

more than the general deductions. In the reporter's own words, it is dangerous to draw conclusions of too general and sweeping a character from experiments upon one type of engine under one set of conditions, but it may fairly be claimed that the ground covered by this report has never previously been surveyed with an engine showing more consistent and definite results, nor under conditions which enabled so detailed an analysis of the results to be made. It may, therefore, be anticipated with some confidence that the definite indications shown by the results form a real contribution to the present knowledge of the phenomena accompanying condensation and re evaporation in an engine cylinder under given conditions of jacketing. The points which have been elucidated may be summarised as follows:

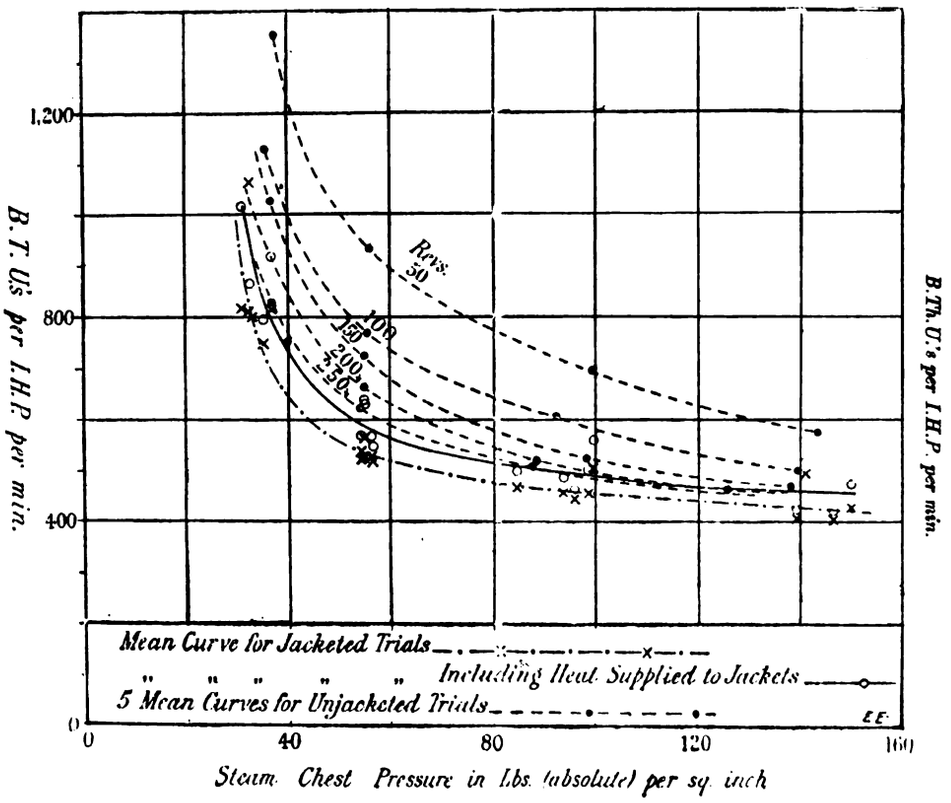

FIG. 1.

Firstly, leakage through the slide valve, to the importance of which Messrs. Callendar and Nicolson have drawn attention, has been quantitatively determined under defined conditions, and has been shown to be nearly independent of speed of sliding surface and proportional to difference of pressure between the two sides of the valve. Further, it has been shown that the assumption that the leakage is inversely as the overlap of the valve is at least in the main well founded. And, further, that with well-fitted valves

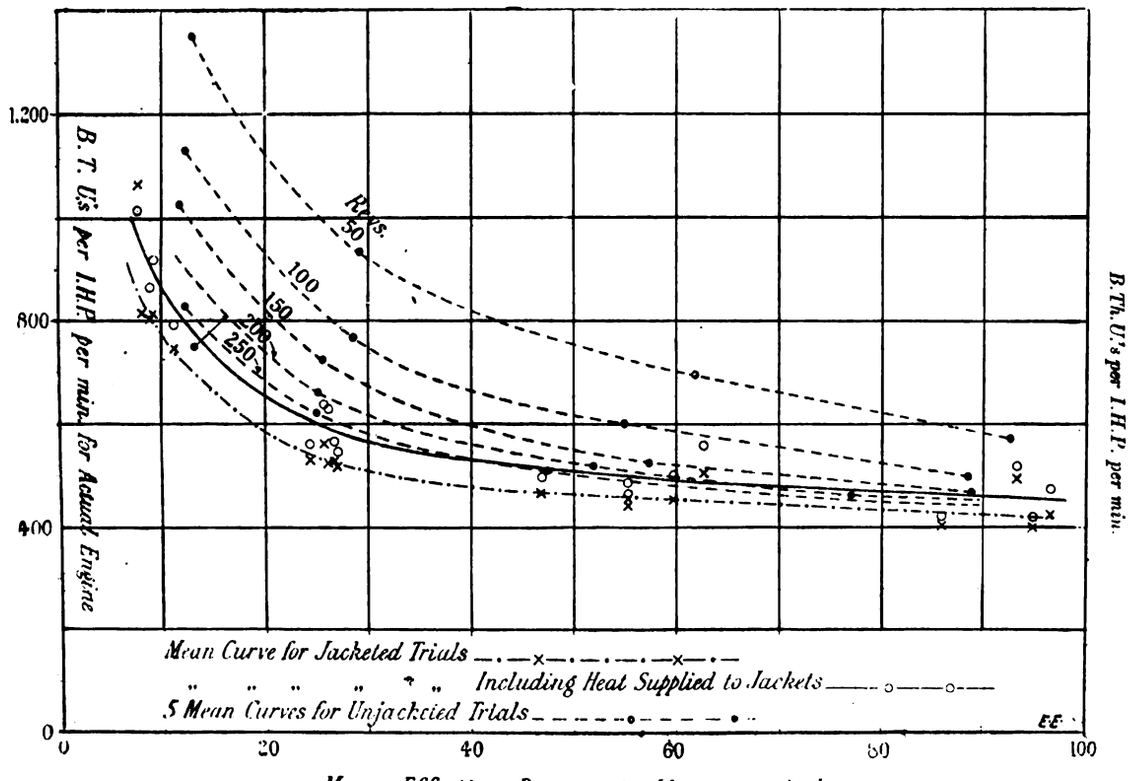

FIG. 2.

Digitized by Google

the leakage may amount to over 20 per cent. of the steam entering the cylinder, and is rarely less than 4 per cent.

Secondly, it has been shown that for an unjacketed engine with a given ratio of expansion initial condensation, expressed as a percentage of the steam in the cylinder, *diminishes* with increase of initial temperature, while the total condensation per stroke *increases* with such temperature increase. This, though suggested by Messrs. Callendar and Nicolson's researches, has never previously been demonstrated with clearness, as if leakage is not allowed for, the results are obscured and even reversed, and the conclusions arrived at without leakage allowance are therefore unreliable.

Thirdly, it appears from the results here obtained that the re-evaporation for a given ratio of expansion is as great and sometimes greater without jackets than with them. This shows very clearly that the regenerative action of the cylinder walls with a given ratio of expansion is largely independent of their mean temperature. No quantitative analysis of re-evaporation is possible where leakage is not taken into account, as without the necessary allowance results would be largely illusory.

Fourthly, it is possible from the results obtained to show the temperature when for any speed of revolution with a given rate of expansion the jackets will become unnecessary or wasteful. If the heat units per indicated horse-power per minute required by the unjacketed engine for each speed of the series be plotted either on an initial pressure or a mean effective pressure base the points for each speed will be found to lie on four curves, which become closer and closer to one another as the speed increases, and all converge to a point as pressure or temperature increases. If the heat consumption for the jacketed series be likewise plotted, it will be found that the points for the different speeds at each pressure lie irregularly round a point, their exact position being determined by the accidentally slight variations of the conditions of each trial. A fair curve through the means of these points will lie below the corresponding curves for the unjacketed trials, but if the heat absorbed in the jackets be included the resultant curve cuts the unjacketed curves at points which for each speed indicate the temperature and pressure at which the jackets cease to be economical. Such curves are shown on Figs. 1 and 2. It will be seen that the full black line, which is the resultant mean for the jacketed trials, cuts both the 250 and the 200 revolution unjacketed curves within the temperatures and pressures included within the scope of the present experiments, and the temperatures and pressures where the 150, 100, and even the 50 revolution curves would cut, can very closely be predicted. As far as the reporter is aware, this is the first time when an exact determination for a given engine and ratio of expansion of this point has been diagrammatically shown.

## TEMPERATURE CURVES AND THE RATING OF ELECTRICAL MACHINERY.*

BY RUD. GOLDSCHMIDT, ASSOCIATE MEMBER.

*(Continued from page 419.)*

### III.—Heating and Cooling.

Temperature curve (Fig. 13) refers to a 440-volt, 4-h.p., semi-enclosed motor. Curve A is actually observed. Curve B gives the temperature curve reduced to constant loss. We gather from the curve that the final temperature, $t_f$, = 64deg. C., and that two-thirds of this final temperature, or 42deg. C., is reached in 72 minutes. The ideal heating time, $T_i$, is therefore 72 minutes. Initial temperature rise $\frac{64}{72}$ = 0·89deg. C. per minute. The current density when the copper was hot was 1·8 amperes per mm.², which, according to Table I., corresponds to 1·05deg C. per minute for cold copper or 1·26deg. C. per minute for hot copper. Through the influence of the cotton insulation the specific heat of the field coil has been increased $\frac{1·26}{0·89}$ = 1·42 times.

* Paper read before the Institution of Electrical Engineers.

The size of wire was 0·028in. With very small high-volt motors it was observed that the specific heat of the thickly-insulated thin wire of the field coils (say 0·012 size) was

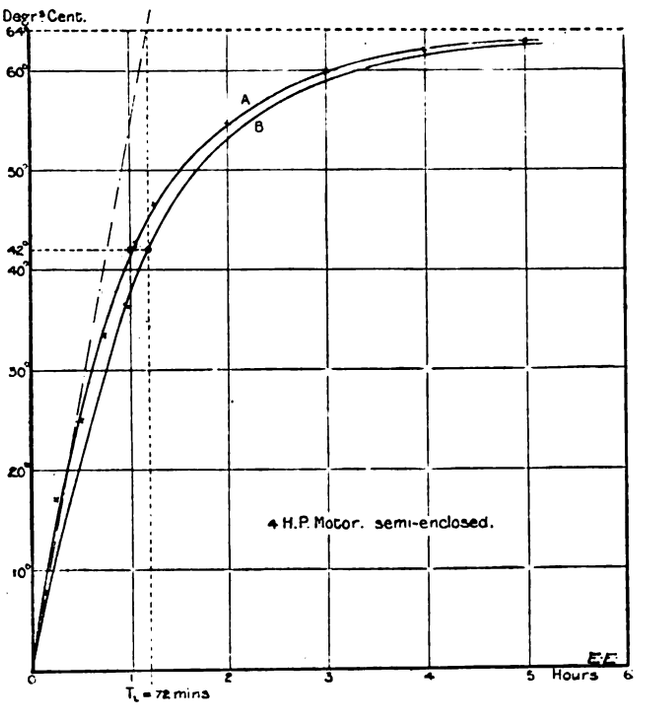

Fig. 13.

nearly double that of pure copper. The following table refers to the curves given in Figs. 6-14:

| Curve Fig. | Output of machine. H.P. | Kw. | Volts. | Type. | Size of wire in inches. | Ideal heating time in minutes. | Current density. Amps. per mm². | Increase of the specific heat through the cotton insulation. |
|---|---|---|---|---|---|---|---|---|
| 6 | — | 750 | 500 | Open | ⅛ sq.in. | 105 | 1·28 | 1·22 |
| 7 | — | 500 | 500 | ,, | ·109 | 108 | 1·25 | 1·25 |
| 8 | — | 200 | 440 | ,, | ·102 | 138 | 1·25 | 1·25 |
| 9 | — | 100 | 440 | ,, | ·088 | 132 | 1 25 | 1 36 |
| 10 | — | 75 | 500 | ,, | ·048 | 75 | 1·58 | 1·42 |
| 11 | — | 55 | 55 | ,, | ·088 | 132 | 1 05 | 1·22 |
| 12 | 35 | — | 110 | Totally enclosed | ·065 | 260 | 1·00 | 1·35 |
| 13 | 4 | — | 440 | Semi-enclosed | ·028 | 72 | 1·8 | 1·42 |
| 14 | 1½ | — | 110 | Totally enclosed | ·028 | 85 | 1 65 | 1·60 |

It is well known that large machines require a very much longer test than small ones. This is very clearly

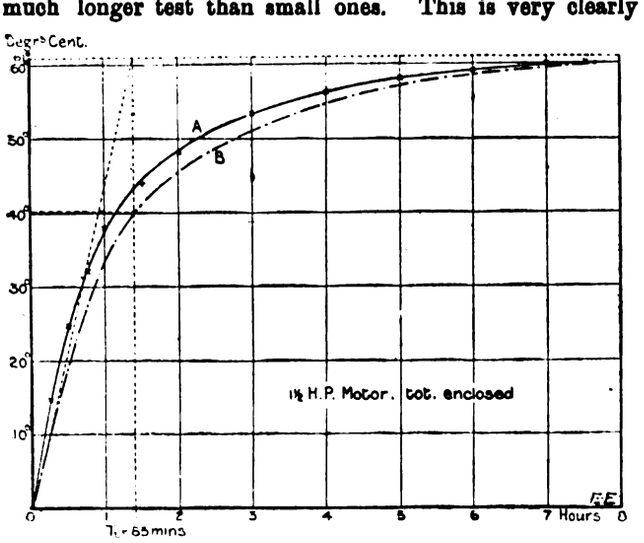

Fig. 14.

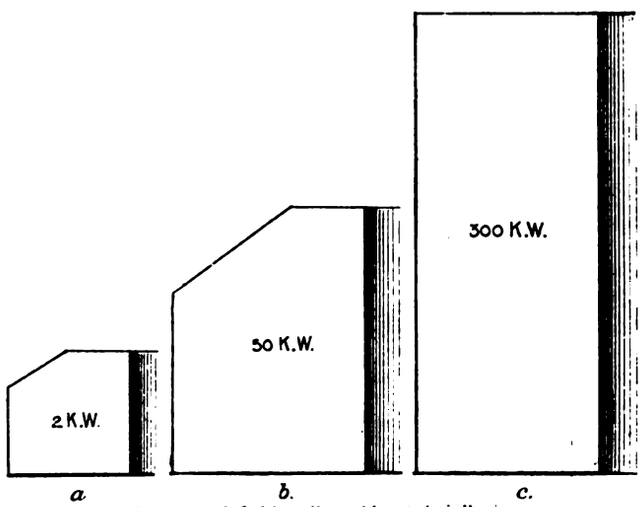
shown by the formula for $T_i$. Whilst heating and rise constants do not vary very much with the size, the ratio $\frac{\text{volume}}{\text{surface}}$ increases with an increase of the size.

Digitized by Google

Fig. 15, *a*, *b*, *c*, shows sections of field coils of 2-kw., 50-kw., and 300-kw. Crompton dynamos. In the case of the 2-kw. machine, the section of the coil is 25cm.$^2$, and the circumference of the section 19·5cm. For the purpose of comparison $\frac{\text{section}}{\text{circumference}}$ may stand for $\frac{\text{volume}}{\text{surface}}$. As an average it may be assumed that 50 per cent. of the total section of the field coils is copper; thus we find

For 2-kw. machine $\frac{\text{section}}{\text{circumference}} = 1{\cdot}3$; $\frac{\text{volume}}{\text{surface}} = 0{\cdot}65$.
For 50-kw. „ „ $= 2{\cdot}0$; „ $= 1{\cdot}0$.
For 300-kw. „ „ $= 2{\cdot}7$; „ $= 1{\cdot}35$.



Section of field coils. About ¼ full size.
Fig. 15.

If for the 2-kw. machine a four hours' temperature test is considered sufficient, the 50-kw. machine must be tested 6¼ hours, and the 300-kw. machine must be tested 8¼ hours. For practical use, the current density will be more convenient for determining the test time than the dimensions. We may, therefore, conclude our investigations on this point by stating that dynamos with stationary field coils, which are designed for about 50deg. C. measured by resistance rise, reach their final temperature within two or three degrees.

| | | | | | | |
|---|---|---|---|---|---|---|
| At the end of 1 hr. with field current density of | 3,000 | amps. | per sq. | in. | | |
| „ | 3 | „ | „ | „ 1,500 | „ | „ |
| „ | 6 | „ | „ | „ 1,000 | „ | „ |
| „ | 9 | „ | „ | „ 800 | „ | „ |

*Example* 2.—A motor has a temperature rise of 50deg. F. with a current density in the field of 1·7 amperes per mm.$^2$

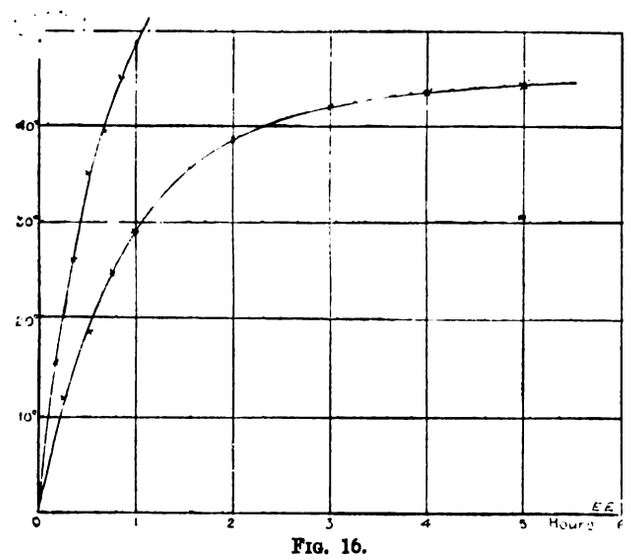


Fig. 16.

What current density should be used if we apply the same machine as a crane motor with 75deg. F. after one hour?

From our original example we know that the ideal heating time is $T_i = 1\frac{1}{2}$ hours. One hour is, therefore, equal to $0{\cdot}67 \times T_i$. At $0{\cdot}67 \times T_i$ (see Table V.) 50 per cent. of the final temperature, $tf$, is reached; therefore, for the crane motor $tf = 2 \times 75 = 150$deg. F. The watts lost can be increased in the ratio $150/50 = 3$ times, and thus the current density may be increased $\sqrt{3} = 1{\cdot}73$ times. As a crane motor with 75deg. F. temperature rise after one hour (measured by resistance), the current density must be $1{\cdot}73 \times 1{\cdot}7 = 2{\cdot}9$ amperes per mm.$^2$—that is, 1,850 amperes per square inch.

A test of a 10-h.p. Crompton motor is also given. Curve A (Fig. 16) is the field temperature rise for continuous running (current density 1·7 amperes per mm.$^2$), while Curve B is a one-hour test with 42 per cent. higher current density—that is, 2·4 amperes per mm.$^2$ We see that the final temperatures of the Curves A and B are the same (46deg. or 48deg. C.). As regards the temperature of the armature, it attained 42deg. C. during the continuous run. The flux went up about 20 per cent. during the one-hour test, in consequence

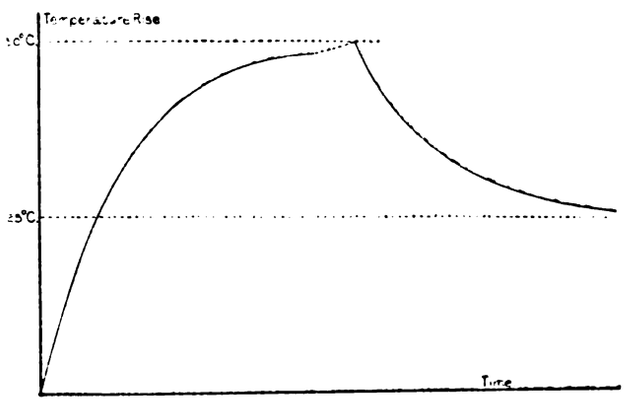

Fig. 17.

of 42 per cent. higher excitation, and the armature current was kept 42 per cent. higher than for the continuous run. The temperature rise after one hour was 38deg. C. This temperature is lower than the continuous running temperature, due to the core loss not having increased in the same ratio as the copper loss.

If a heated body has attained the temperature which we have called the "final temperature," all heat subsequently produced is given out to the surrounding atmosphere.

Referring to our previous example again, we stated that if the body has a temperature of 50deg. C. above that of the atmosphere it gives out by radiation and convection as much heat as would increase the temperature of the body at the rate of 0·55deg. C. per minute. With a temperature of only 35deg. C. we found the state to be inconstant, the temperature increasing at the rate of

$$\frac{0{\cdot}055}{50}(50-35) = \frac{1}{90} \times 0{\cdot}15 = 0{\cdot}165\text{deg. C. per min.}$$

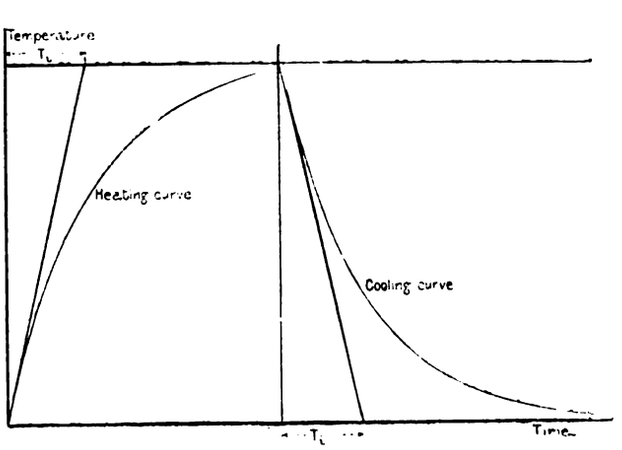

Fig. 18.

Now we know that the ideal heating time

$$T_i \frac{50}{0{\cdot}55} = \frac{\text{Final temp.}}{\text{Initial rise}} = 90\text{min.}$$

and is a constant of the apparatus, so that we may say

Digitized by Google

$$\text{Temp. increase per min.} = \frac{\text{Final temp.} - \text{momentary temp.}}{\text{Ideal heating time.}}$$

$$E = \frac{tf - t}{T_i} = \left(\frac{50 - 35}{90}\right).$$

We will suppose that the temperature was more than the temperature of equilibrium, 50deg. C.—say 70deg. C. We may assume that this temperature was obtained by overloading the apparatus at some time. Then the cooling action is 70/50 = 1·4 times greater than that which just balances the temperature increase of 0·55deg. C. per minute. Thus at the instant when the temperature of the body cools down at the rate of $E = \frac{50 - 70}{90} = 0$ 22deg. C. per minute, we see that there the calculation of the cooling is the same as that of the heating, and if E is positive it indicates temperature increase, while if negative it indicates a cooling action.

It is important to consider the cooling curve in cases where the development of heat suddenly becomes less. Supposing the lost watts were suddenly reduced by half (Fig. 17), then the new final temperature would be $\frac{1}{2} \times 50 = 25$deg. C., and the initial rise $\frac{1}{2} \times 0{\cdot}55 = 0{\cdot}275$deg. per minute. If the body had already attained its end temperature of 50deg. C. during the first instant after the change, the temperature would drop at the rate of $\frac{25 - 50}{90} = -0$ 275deg. per min. At any other temperature the calculation of the temperature drop is equally easy; at 35deg. C., for instance, we find $E = \frac{25 - 35}{90} = -0{\cdot}11$deg. per minute. Proceeding by intervals of 10 or 20 minutes, we can trace the whole cooling curve, which tends to reach the new final temperature of 25deg. C.

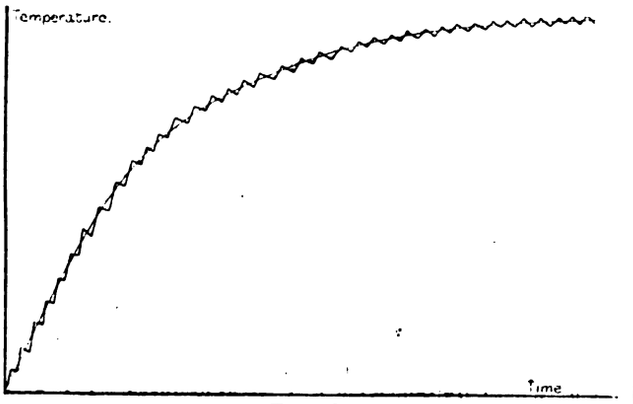

FIG. 19.

By a complete heating and cooling curve we understand the heating curve rising up to the final temperature, and the drop curve from this temperature down to 0 = air temperature. The rate of the drop in the first moment is $\frac{50 - 0}{90} = 0{\cdot}55$deg. C. per minute, being the same as the initial rise. Therefore, we see that the initial rise and the initial drop are identical. The "total rise" was 0 to 50deg. C.; the "total drop is naturally the same amount—*i.e.*, 50deg. C to 0. This is sufficient to show us that the falling curve and the rising curve are identical in form, only reversed. The consequence is that we are able to apply the same graphic method as that described in connection with Fig. 3, and that after finding the correct scale in the manner previously described, we can use Fig. 4 upside down as a standard cooling curve for every possible case.

The tables can also be easily adapted to the cooling curve. Table V. shows, for instance, that the machine is heated up from 0 to 75 per cent. of the final temperature (in our example $0{\cdot}75 \times 50 = 37\frac{1}{2}$deg. C.) in $1\frac{1}{2} \times$ the ideal heating time, $T_i$ ($1\frac{1}{2} \times 90 = 135$ minutes). Bearing in mind that the cooling curve is a heating curve (only reversed), we may say that in $1\frac{1}{2}$ times $T_i$ the body is cooled down from 50deg. C. to 100 per cent. − 75 per cent. = 25 per cent. of the final temperature—that is, in the example, to $0{\cdot}28 \times 50 = 12\frac{1}{2}$deg. C. If the load is only reduced in such a degree that the losses are halved, the new final temperature to which the body would tend to cool down is $\frac{1}{2} \times 50 = 25$deg. C.

With reference to the above, we found that the initial rise in this case is 0·275deg. C. per minute. The total amount to be cooled down is 50 − 25 = 25deg. C., thus the "ideal cooling time" is $T_i = \frac{25}{0{\cdot}275} = 90$ minutes, just as for the heating time, and consequently in, say, $1\frac{1}{2} \times T_i = 135$ minutes, the body has cooled down $0{\cdot}75 \times 25 = 19$ deg., and so reached a temperature of 50 − 19 = 31deg. C.

Before concluding our investigations on cooling, it may be pointed out that with rotating machines during the cooling period, when the machine is shut down, the cooling conditions generally are worse than those existing when the machine is working. This is due to there being no ventilation when the machine is at rest. When the machine stands still, the heating constant (equivalent to cooling constant) of the field coils is about two-thirds of that with the machine revolving at normal speed. This ratio naturally depends on the sort of machine, and on the influence of the armature losses on the field temperature, etc. It would, however, be beyond the scope of our real subject to consider this question fully in the present paper. We will, therefore, only study in principle how a change in the degree of ventilation influences the temperature curve.

*(To be continued.)*

## FORTHCOMING EVENTS.

FRIDAY, MARCH 31.

**Compatriots' Club.**—At 5 30 p.m., Westminster Palace Hotel, "The New German Commercial Treaties and their Probable Effect on British Industries," by Mr. W. A. S. Hewins.

**Institution of Mechanical Engineers.**—At 8 p.m., "First Report, Steam-Engine Research Committee," by Prof. D. S. Capper (further discussion).

SATURDAY, APRIL 1.

**Association of Municipal Corporations.**—Annual meeting at the Guildhall, when the agreement between the National Telephone Company and the Government and other subjects will be discussed.

**Royal Institution.**—At 3 p.m., "Some Controverted Questions of Optics," by Lord Rayleigh.

MONDAY, APRIL 3.

**Society of Arts.**—At 8 p.m., Cantor Lecture IV., "Telephony," by Mr. H. L. Webb.

TUESDAY, APRIL 4.

**Institution of Civil Engineers.**—At 8 p.m., further discussion on Mr. C. S. R. Palmer's paper, "Coolgardie Water Supply."

THURSDAY, APRIL 6.

**Institution of Electrical Engineers.**—At 8 p.m., discussion on the report to Council on the International Electrical Congress, St. Louis, by Mr. W. Duddell, hon. secretary to the delegation, and on the papers on "Systems of Electric Units," by Profs. Ascoli, G. Giorgi, H. S. Carhart, and G. W. Patterson, and Dr. F. A. Wolff.

**Chemical Society.**—At 8 p.m., general meeting.

**Royal Institution.**—At 5 p.m., "Synthetic Chemistry," by Prof. R. Meldola.

**Rontgen Society.**—Exhibition evening.

FRIDAY, APRIL 7.

**Compatriots' Club.**—At 5.30 p.m., Caxton Hall, "The Economics of Preference," by the Hon. B. R. Wise, K.C.

**Royal Institution.**—At 9 p.m., "American Industry," by Mr. A Mosely.

**Institution of Electrical Engineers (Manchester Students' Section).**—At 7.30 p.m., "Electric Cranes," by Mr. Jennison.

SATURDAY, APRIL 8.

**Birmingham Electric Club.**—At 7.30 p.m., "Lightning Conductors," by Mr. W. H. Whitehouse.

---

**Institution of Civil Engineers.**—The thirteenth "James Forrest" lecture will be delivered by Colonel R. E. C. Crompton, R.E. C.B., on Monday, April 10, at 8 p.m., the subject being "Unsolved Problems in Electrical Engineering."

**Physical Society.**—April 14, "Ellipsoidal Lenses," by Mr. R. J. Sowter; "The Determination of the Moment of Inertia of the Magnets used in the Measurement of the Horizontal Component of the Earth's Field," by Dr. W. Watson; and a series of lecture experiments illustrating the properties of the gaseous ions produced by radium and other sources, by Dr. W. Watson.

## TRADE NOTICES AND NOVELTIES.

### Catalogues.

EDISWAN LEAFLETS.—Two leaflets illustrating new designs of fancy glass shades and globes have been sent to us by the Edison and Swan United Electric Light Company, Limited, 36-37, Queen-street, Cheapside, E.C.; also one dealing with fuseboards of the "terminal" type, specially suitable for motors or for controlling large lighting circuits.

ELECTRICAL COMPANY'S LITERATURE.—A mass of literature has been issued recently by the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C. This includes a comprehensive price-list of rubber wires and cables, a descriptive list of E.C. ampere-hour motor meters of the firm's R.A. type, and leaflets illustrating respectively their double-tariff meter combination, automatic cut-off switch for shop windows, lamp signs, etc., weatherproof motor switchboard, motor switch and starting box, electric capstan and 50-ton crane at Southampton Docks with E.C. electrical equipment.

STANDARD SCREW THREADS, Hampshire Works, Station-road, Walthamstow, N.E.—New lists have been issued of the British Association standard screw threads, of which the firm are the original makers, and we are informed that they will supply these free of charge and post free to any of our readers who use or are interested in taps, screw plates, dies, etc., not only of the B.A. type, but any other.

### G.E.C. Progress Sheet.

The Progress sheet issued by the General Electric Company, Limited, 71, Queen Victoria-street, E.C., for February last includes particulars of several novelties, some of which we illustrate herewith. Fig. 1 shows a new heavy pattern of sealing-wax heater for workshop use. It is wired for two circuits, one for heating the wax up quickly, and the other for maintaining it at the right consistency. Fig. 2 shows a new design of battery fan. The fan motor in this combination is constructed with a permanent magnet field, which enables a much higher efficiency to be obtained than is usual. Our last illustration (Fig. 3) represents a handy form of inspection lamp fitting for motorists. The lamp itself is of the "Osmi" type, and is claimed to give a good light when connected to an ordinary ignition battery. A very compact form of tail fitting, with "Osmi" lamp for motor cycles and cars, is described, and particulars are also given of a lampholder designed to prevent the withdrawal of lamps by unauthorised persons. When the lamp is inserted in the holder, a special stud at the top is turned by means of the key provided, and this effectually locks the spring contacts, thus preventing the removal of the lamp.

FIG. 1.—Sealing-Wax Heater

FIG. 3.—Inspection Lamp Fitting for Motorists.

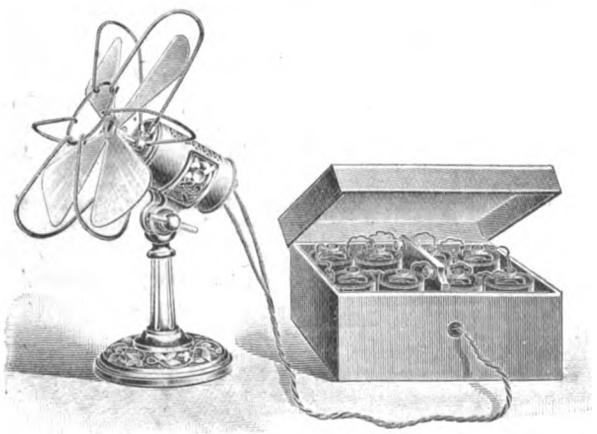

FIG. 2.—The Magnet Battery Fan.

### Electrically-Driven Pumps.

In our issue of Feb. 10 last we referred at some length on p. 202 to a standard line of electrically-driven variable-stroke boiled feed pumps of very excellent design, which Messrs. Hayward-Tyler and Co., of 99, Queen Victoria-street, London, E.C., are manufacturing at their Luton Works under the Sinclair patent. Since then we have received from the above firm a copy of their new catalogue, Section M, dealing with electrically-driven and other three-throw pumps. Incidentally, this catalogue serves to show the very rapid strides that electricity is making as a flexible and convenient means of applying power to pumps. The adaptability of the pumps is practically unlimited, ranging from domestic water supply, boiler feeding, etc., to fire protection and mines drainage. It is also noteworthy that the illustrations are from actual photographs, and represent a selection of the many patterns supplied by Messrs. Hayward-Tyler and Co. For special reference we have selected the two combinations illustrated repectively on pp. 22 and 23 of the catalogue. The first of these (Fig. 1 herewith) is a 3in. by 6in. vertical treble-barrel pump, coupled through gearing to an electric motor. This pump was designed for delivering 1,500 gallons per hour against a head of 300ft. The whole is enclosed in a strong wrought-iron case with chains for suspending, and was built for use in mines. It will be noticed that the motor is provided with hinged covers to allow for easy access. Fig. 2 shows a 3½in. by 6in. horizontal three-throw plunger pump geared by machine-moulded cast-iron gearing to a

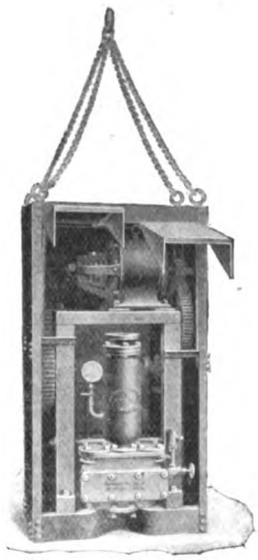

FIG. 1.

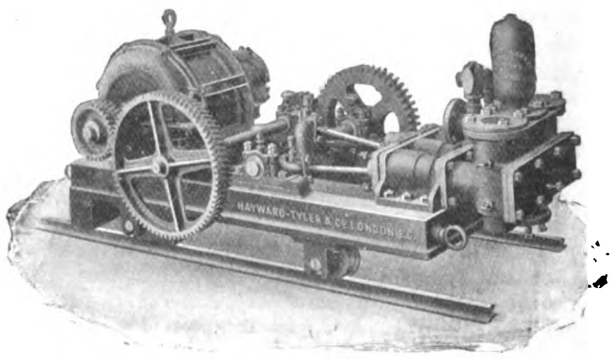

FIG. 2.

Digitized by Google

continuous-current electric motor, and mounted on a travelling truck. This combination was supplied to a large ironworks, and is capable of delivering 3,000 gallons per hour against a head of 80ft. We need not dwell here upon the great advantage of electrically-driven over steam-driven pumps for portable purposes in mines, etc., but in this connection we are glad to have Messrs. Hayward-Tyler and Co.'s assurance that for most purposes the flexibility and convenience of electricity as a motive power for pumps is being fast recognised, as proved by numerous orders and enquiries for all ranges of their machines, including mining pumps of the largest sizes.

## "Pluto" Electric Heaters.

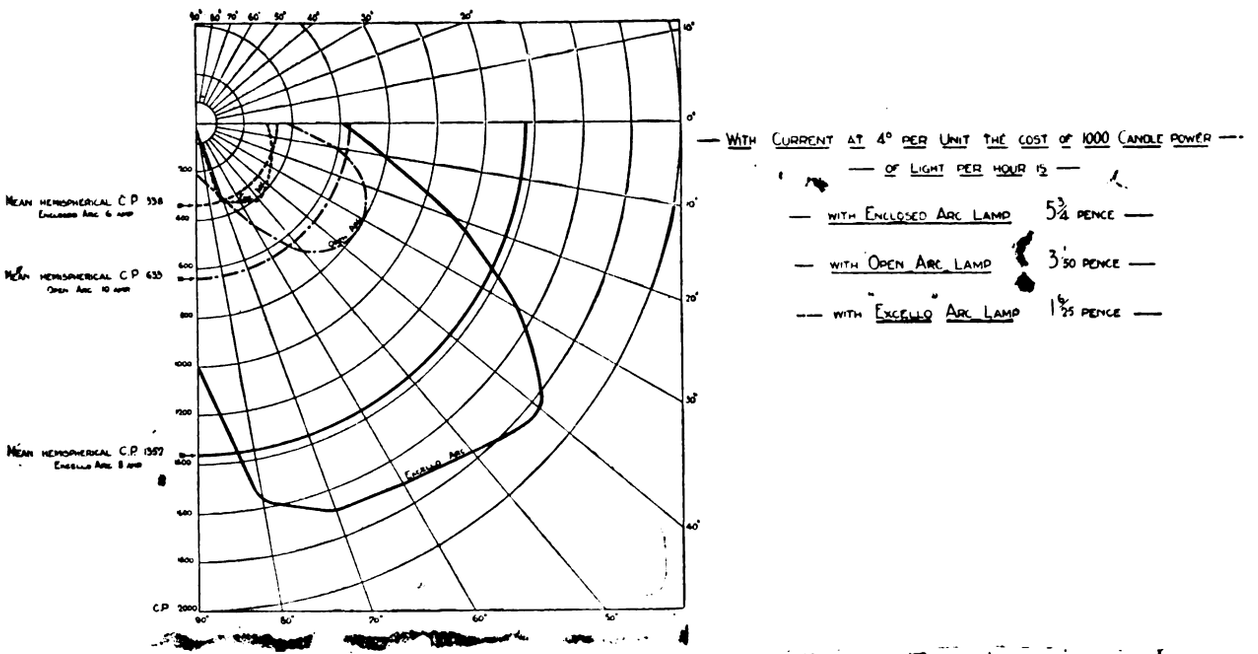
We were invited last week by the Electric Corporation, Limited, to inspect a selection of their "Pluto" electric heaters at 69-70, Aldersgate-street, E.C. These heaters mark an entirely new departure, and for æsthetic reasons alone will scarcely fail to secure a very large demand. Great care has, in fact, been taken to obtain artistic designs, the possibility of art metal work being fully developed, while some of the styles shown will appeal very strongly to lovers of the antique. It may be truly said that each "Pluto" heater is not only an article of utility but a piece of furniture deserving of admiration. Apart from artistic merit, the great feature of these heaters is the principle which they combine. The heating medium consists of resistance wire of special non-oxidising alloy wound spirally on porcelain cores having concave sides to admit of the free circulation of air immediately round the wire. Each core so wound constitutes a section, and can be easily replaced in case of breakage, which is, however, extremely unlikely. A number of these sections are combined in one heater, and regulation is obtained by switching in the whole or part of them as required by means of two switches which govern three temperatures. The sections are enclosed in a metal chamber provided with a thick covering of asbestos material. Open-ended tubes or ducts pass vertically through this chamber, which quickly becomes a reservoir of heat when the electric current is switched on, with the result that the tubes are raised to a high temperature, air being drawn through them, heated, and freely circulated. The asbestos covering of the heating chamber, of course, tends to conserve the heat, so that when the circulation is once started, less current is required to maintain it, and some of the sections can, therefore, be switched out. Practically all the heat generated is usefully employed, hence economy. The latter is claimed to be high, and we have no reason to doubt but that it is so, but as exhaustive tests are not yet completed we must, perforce, reserve full information for a later date. It is estimated, roughly, that 500 watts will suffice to heat 1,000 cubic feet of air-space, but the figures vary with the conditions obtaining. One heater, which we were informed was taking 2½ amperes at 200 volts, recorded a temperature of 300deg. F. of the heated air. In some of the heaters a fan is fixed above the tubes, being rotated by the ascending air, which it forces through pierced side panels, thus circulating a layer of hot air at a low level. Such heaters can be placed anywhere for effect. We hope to deal with "Pluto" heaters more fully in a subsequent issue.

## Excello Arc Lamps.

Below we give the results of some comparative tests for candle-power and efficiency made by the Westminster Electrical Testing Laboratory with the Union Electric Company's Excello flame arc lamp and two other types. It will be seen that the figures are very favourable to the Excello type, and amply substantiate the claims which the makers have made from time to time, while they explain the great success with which these lamps are meeting. The types compared were respectively as follows: ordinary open-type arc lamp, rated at 10 amperes, and fitted with cored carbon in top and solid carbon in lower carbon-holders; enclosed arc lamp, rated at six amperes, and fitted with solid carbon top and bottom; the Excello flame arc lamp, rated at 8 amperes, with arc burning horizontally, burning Noris-Excello carbons Nos. 104 105. All three lamps were provided with alabastrine globes. The amount of light obscured by the globes appeared to be the same for all three lamps. The same photometer, light standard, and instruments were used throughout. Following are the details of the tests:

*Electrical Details.*

| | Open arc. | Enclosed arc. | Excello arc. |
|---|---|---|---|
| Positive carbon ..... | 18mm. cored | 13mm. solid | 9mm. flame |
| Negative ,, ..... | 12mm. solid | 13mm. ,, | 8mm. ,, |
| Mean current in amperes ... | 10·8 | 6·25 | 8·7 |
| Mean pressure in arc volts | 44·0 | 77·6 | 44·0 |
| Mean consumption in watts (Shunt included) | 476 | 485 | 382 |



CANDLE POWER CURVES OF THREE TYPES OF ARC LAMPS TESTED AT WESTMINSTER ELECTRICAL TESTING LABORATORIES.

EXCELLO, OPEN ARC, ENCLOSED ARC. 11TH MARCH 1905.

*Candle-Power Details*

| Angle below horizontal. | Candle-power. Open arc. | Enclosed arc. | Excello arc. |
|---|---|---|---|
| 0 degrees ..... | 353 ..... | 290 ..... | 600 |
| 10 ,, ..... | 390 ..... | 308 ..... | 760 |
| 20 ,, ..... | 735 ..... | 330 ..... | 1,120 |
| 30 ,, ..... | 800 ..... | 350 ..... | 1,520 |
| 40 ,, ..... | 790 ..... | 382 ..... | 1,830 |
| 50 ,, ..... | 690 ..... | 410 ..... | 1,750 |
| 60 ,, ..... | 490 ..... | 360 ..... | 1,700 |
| 70 ,, ..... | 330 ..... | 345 ..... | 1,680 |
| 80 ,, ..... | 250 ..... | 75 ..... | 1,560 |
| 90 ,, ..... | 210 ..... | 30 ..... | 1,000 |
| *Results.*—Mean hemispherical candle-power. | 633 ..... | 338 ..... | 1,352 |
| Watts ..... | ·753 ..... | 1·435 ..... | ·282 |

From the above it appears that the watts per mean hemispherical candle-power is in the case of the Excello arc lamp but 37·5 per cent. of that obtained with the open arc and 19·65 per cent. of that obtained with the enclosed arc. It is added that it was impossible to test the Excello lamp without globes, as its candle-power was then higher than could be measured in the photometer room, but assuming that the globe absorbed the same amount of light as that fitted to the open arc, the mean hemispherical candle-power without globe should work out at about 2,300 c.p. The accompanying illustration shows the polar curve plotted from the measured figures of candle-power. It remains for us to congratulate the Union Electric Company, Limited, of 151, Queen Victoria-street, E.C., on the above results.

## MANCHESTER MAINS.

### An Appreciation of a Slandered System.

It would appear to the casual reader of the recent legal proceedings against the Corporation of Manchester (on account of premises damaged by fire caused by a fault on the electric mains) that there was something particularly rotten about the system of electrical distribution adopted by that Corporation, if the verdict of the jury is to be considered of value. Briefly, the verdict stated (1) that the system constituted a *nuisance*, by causing danger to persons having premises adjacent to the mains; (2) that the electrical authorities were guilty of *negligence* in their methods of localising the fault in question; and (3) that when this fault developed it was *improperly* dealt with as regards fire risks. Electrical men will be considerably interested in the verdict all over the country, and especially those connected with systems of distribution which may be likened to the Damoclean sword, as regards their factor of safety from destructive breakdown. These latter will probably liken the system that has been so severely questioned to their own happy-go-lucky arrangements, numbers of which, alas! still exist all over the kingdom; and it is likely that those in charge of such hair-bleaching networks will take a none-too-soon warning from the incident.

There are other systems existing, however, with but one quarter of the precautions taken by the Manchester authorities, which are enjoying an immunity from serious accident due to their more favourable present circumstances, and whose superintendents will possibly look upon the Manchester affair as a providential retribution for inefficiency and shortsightedness. And it is these superior persons that require to be assured of the absolutely unique position of the Manchester Corporation electricity concern, both as to efficiency and longheaded precautions for the future. It should here be said that this article is not written for the sole purpose of justifying the Corporation staff against the legalised slanders of last week, but to point out that though a certain system of distribution may come an occasional and perfunctory cropper, it is no proof that other systems are, therefore, of more all-round value.

As regards the design of the network, it must not be imagined that the accidents that have happened were due to ignorance of the conditions. The system was originally laid down by Mr. C. H. Wordingham, and, right or wrong, he evidently fully appreciated the risks that were to be run, as per the following extract from his book on central stations, published in 1901. This extract shows that the system is based upon "the best means of maintaining continuity of supply," damage to property being apparently a secondary consideration.

Now, in all except the smallest towns, it is desirable to connect up the distributing mains to form what is known as a network—*i.e.*, wherever distributing mains meet conductors of the same polarity are connected together. There may be either one large network, or a number of isolated ones.

The argument in favour of one network is very strong. By interconnecting all points as far as possible, and by joining up every street at both ends, there is established, as it were, a conducting sheet on each pole from which current can be drawn, and if the demand is excessive at any one point the supply can flow to that point from all directions. The importance of this is great, for, in spite of great experience, it is impossible, in laying distributing mains, to avoid occasionally under-estimating the demand in a given street. If these distributors are connected at several points to the rest of the network, this is of little moment. Moreover, the area of maximum demand is constantly shifting from hour to hour, and with one large network less copper is required to deal with this than with a number of isolated networks, each of which must be large enough for its own maximum. Again, if the position of the demand has not been accurately foreseen, and the feeding point has not been placed in exactly the right spot, the error is practically eliminated by the network. With such a system, also, there is much less chance of being unable to reach a consumer in case of a fault.

Against these advantages there would be nothing to urge, if one could be certain that the insulation of the mains would always continue intact; but the best of mains will fail sometimes, and the consequences are then much more far-reaching than if there are a number of small independent networks. *In point of fact, it is a question of the best means of maintaining continuity of supply.* If it were feasible to arrange an automatic cut-off, whether in the form of a fuse or a mechanical circuit breaker, so as to isolate any section of mains which become faulty, there would be no question that one network is preferable; but, unfortunately, such a system of cut-outs is practically impossible at the present time. For, imagine a complicated network arranged with a cut-out on every section of main, and suppose a short-circuit on a given section, this short-circuit would allow a large quantity of current to flow for a short time. If all was in order, the circuit breakers on that section of main would be thrown; but, in order to throw these circuit breakers, large currents must have flowed through other portions of the network in order to reach this section, with the inevitable result that the circuit breakers on these portions, which are also set to cut off with extra current, are thrown as well, a dozen cut-outs, perhaps, going out of several hundred, and there may be but a slight clue as to where these cut-outs are, as the course taken by the current will vary according to the conditions of the load at the time.

Another great difficulty in using cut-outs arises from the fact that if the outer conductors of a distributing main be interrupted between two feeding points, and there are no balancers on the section, the lamps on the circuit or circuits which have the smallest load will be subjected to an undue pressure - this alone is almost fatal to the use of cut-outs.

If the question once be faced that a short-circuit cannot be efficiently provided against by means of cut-outs, but has to be burnt out, then the advantages of a large network become manifest, for the relative importance of a short-circuit diminishes as the extent of the scale of operations increases. Consider the case of a station supplying half a million lamps, and distributing at 400 volts. When all lamps are alight, their combined resistance between the outer conductors is only about one four-hundredth part of an ohm, and it must be an extremely bad short-circuit which has, and can maintain, as low a resistance as this. There is a good chance of burning out a fault quickly if the network will admit of heavy currents being delivered at any point.

From this it will be seen that the conditions under which the Corporation network exists are somewhat severe, and it is clear that this has been fully recognised by the Corporation electrical staff, and that the risks have been provided for to the best of their ability.

One item in the evidence may be taken as an example of what is meant. Mr. James Swinburne stated that with the exception of the five-wire arrangement, everything in the system was standard. This is only partly correct. As mentioned by Mr. L R. Lee (the Manchester mains engineer) in a letter to this paper of Oct. 30, 1903, he is no believer in standard practice, except, perhaps, as a minimum basis upon which to build his own more solid designs, and this is well known by those who have dealings with the Manchester Corporation. Take the insulation of the Manchester cables, for example. In them the Cablemakers' Association thicknesses of dielectric (which are the recognised standards) are exceeded up to double their values. The lead sheathing is also increased from the Cablemakers' Association's well-used standards in like proportion. Take the method of laying cables. Where other corporations almost universally use ½in. clearance between cables on the solid system, the Manchester standard is ¾in. Where others use wood and pot troughs, Manchester has cast iron, which are socketed and bolted together; and, further, her extra high-tension cables laid therein are earthed to every yard of trough by malleable iron clips. As to facilities for disconnecting, the arrangements are also unique in the provision of specially constructed pillars in roomy boxes, built like strong rooms, well ventilated, drained, and generally kept in drawing-room order. Every cable entering these chambers is distinctively and vividly coloured, and is clearly labelled as to size and route. If there were prizes offered for the condition of underground arrangements (similar to railway station competitions in floriculture), the Manchester system would romp home, judging from what the writer sees upon networks all over the country.

In conclusion, while justice appears to have been done in making the cause pay for the effect, there was surely no need to add insult to damages by using the three epithets mentioned in the opening paragraph to a system whose strong points (apart from the question of original design) are its thorough efficiency and provision for the future.

# LEGAL INTELLIGENCE.

## MIDWOOD v. CORPORATION OF MANCHESTER.

Our last week's issue contained a report of this case, in which judgment was delivered as we were going to press.

**Mr. Moulton, K.C.**, in concluding his speech for the defence, submitted that the defendants had acted perfectly correctly in difficult circumstances.

**Sir E. Clarke, K.C.**, replying on the whole case, said Mr. Moulton had spoken as if the defendants were not liable because they had complied with all the Board of Trade regulations. That was not the law, and the jury had nothing to do with the statutory rights and obligations of the Corporation or the regulations of the Board of Trade. The Legislature had known perfectly well how to deal with the danger which must inevitably occur to persons in the neighbourhood of electric works, because there was a special clause in the provisional order under which the defendants were empowered to carry out these works, saying, "Nothing in this order shall exonerate the undertakers from any indictment, action, or other proceeding for nuisance in the event of a nuisance being caused by them." That special provision got rid of all the regulations and rules of the Board of Trade. The evidence for the defendants was that the risk of burning up houses was a necessary incident of their system. If that was so, then it was clearly a nuisance which had been brought to the doors of the inhabitants by the Corporation, and they were undoubtedly liable for any damage which was caused by such a nuisance. They admitted that it was impossible to foresee these occurrences, and, therefore, any private person was at the mercy of this system. Fortunately, in this case, the premises damaged were a warehouse, but the consequences might be serious if a similar accident happened to a house where there were a number of people asleep. The reports put in showed that there had been 20 accidents in three years, and his learned friend was mistaken in saying that no compensation had been paid, because in one case the Corporation paid £100. Of course, the other persons who were injured did not care to run the risk of bringing actions against the Corporation, which would be conducted in the way this case had been, at enormous expense to all parties. This case, however, involved a substantial amount as well as an important principle, and he hoped the result of it would be to secure that in future, when accidents took place by which private persons were damaged, they would be properly compensated.

**His Lordship**, in summing up, pointed out that the allegations of nuisance and negligence stood on entirely different grounds. If a person created a nuisance, it was no answer for him to say that he had not acted negligently. On the allegation of negligence the question was, did the defendants' servants take all reasonable steps to localise the fault, and if they had done so, could they have prevented the fire? The evidence on which the plaintiffs relied to support the charge of negligence was that earlier in the evening the defendants' servants had information of the irregularity in the light of the public-house in Fountain-street, but, notwithstanding that information, they did nothing to disconnect the supply in Fountain-street until it was too late. The two questions he left to the jury were, did the system adopted by the defendants constitute a nuisance by causing danger to persons having premises adjacent to the mains; and when the defendants became aware of the fault did they deal with it for the purpose of preventing fire in a reasonable and proper manner? At the request of Mr. Gordon he included a third question—Were the defendants guilty of negligence in their method of localising and dealing with faults?

The jury, after a short deliberation, returned answers to all the questions in favour of the plaintiffs.

**Sir E. Clarke**, in asking for judgment for the plaintiffs, asked his Lordship to rule in his favour that on Section 67 of the provisional order authorising these works the plaintiffs were entitled to judgment, whatever the jury's verdict might have been. He only wanted to protect himself on the point of law in case the matter had to be argued in the Court of Appeal.

**His Lordship** said he would not rule on the point, but he had made a note that Sir E. Clarke had taken the point, so that he could argue it hereafter if necessary.

Judgment was then entered for the plaintiffs for the amount agreed as damages, £677, with costs.

## BATH ELECTRIC TRAMWAYS.

An appeal by the plaintiffs from the judgment of Mr. Justice Farwell in the case of Longman *v.* the Bath Electric Tramways, Limited, was concluded on Tuesday.

Plaintiffs purchased 1,500 preferred ordinary shares of £1 each in the Bath Electric Tramways, Limited, registered in the name of Mr. Peter Bennett. The transfers were left at the company's office for registration, and a few days later the company's solicitors wrote to the plaintiffs stating that the shares had been previously transferred by Mr. Bennett, and that, therefore, the company could not part with the certificates. It seemed that when the shares were previously dealt with, the company by mistake sent the transfer for 1,500 shares to Mr. Bennett, and he failed to comply with a request to return it. The plaintiffs then sued the company to have the shares registered in their names and to recover damages. Mr. Justice Farwell held that there was no cause of action against the company, and dismissed the action, with costs.

**Lord Justice Vaughan-Williams**, in giving judgment, said he thought the judgment of Mr. Justice Farwell ought to be affirmed, because plaintiffs had not been misled by the statements or conduct of the company, and that the company had not been shown to have been negligent of any duty which was owed to the plaintiffs individually or as members of a section of the public, and the negligence which had been shown in the certificates in question was not the immediate or real cause which led to the loss of the plaintiffs.

Appeal dismissed.

## MOTOR LAW PROBLEM.

At the North London Police Court, Claud Clench, electrical engineer, was summoned on Monday for neglecting to have a distinguishing number affixed to the general identification mark.

**Mr. Staplee Firth** raised the novel point that it was the London County Council who were responsible for the absence of a number on the identification plate. Under the Act each manufacturer was assigned an identification mark, and the assigned mark in this case was "A L R." Nothing was said by the Council's officials about a number. Mr. Firth went on to contend that the section of the Act, though badly drafted, implied that a number was necessary in addition to the identification mark only where the manufacturer had more than one car in use.

The **Magistrate**: That is quite a new point.

**Mr. Firth**: I have never heard it raised before.

The **Magistrate**: It looks, on the face of it, as if the Council's mark assigned to your client is null and void, but whether that relieves him from the consequences of an infraction of the Act was another matter. His Worship deferred his decision.

## FIRE AT OLYMPIA.

It will be remembered that during the recent great automobile show at Olympia, it was reported that a fire had broken out on one of the stands, owing to an electric cable fusing in a showcase of the United Motor Industries. Arising from this an action was brought by the United Motor Industries, claiming £61 damages from the contractor for the lighting, Charles Oliver Clark, trading as Oliver Clark and Co.

The Judge, in summing up in defendant's favour, said: "The case has been most interesting. The issues of the case were of considerable importance to the defendant, he being an electrical engineer in a very large way of business, and his reputation was now at stake. It must be remembered that he laid on the electric light to 34 other stands at the motor exhibition without any fault being found in respect of any one of them." The expert evidence produced by the defendant left no doubt as to the cause of the supposed fire, and although the trial had occupied the attention of the Court for two whole days, the judge did not think five minutes had been wasted. The result of numerous experiments were fully appreciated by the jury, who, after retiring for a quarter of an hour, returned and said they were of opinion that the fire was not caused through defective work on the part of the defendant, but through celluloid being placed in too close proximity to the electric lamps. His Honour accordingly gave judgment for the defendant on claim and counterclaim, with costs.

## CLEARING SNOW FROM TRAMWAY LINES.

An action was heard by Sheriff Mackenzie at Airdrie last week, in which the Town Council sought recovery of £7. 0s. 8d. from the Airdrie and Coatbridge Tramways Company.

The plaintiffs had to clear away accumulations of snow left on the street through the defendants using a snow-plough. The defendants contended that the Town Council as local authority were bound to keep the streets clear of snow, and they lodged a counterclaim of £10 for having cleared part of the street for them. The Sheriff, after hearing evidence and argument on the point, held that the Aberdeen case ruled in this matter, and gave judgment for the plaintiffs.

# COMPANIES' MEETINGS AND REPORTS

## BRITISH INSULATED AND HELSBY CABLES.

The annual meeting was held at Liverpool on Monday, Mr. E. K. Muspratt (chairman) presiding.

The **Chairman**, in moving the adoption of the report (of which we gave particulars last week), said that having regard to the continued keen competition in the trade, the report would probably be regarded as satisfactory, especially in view of the fact that the increased price of rubber referred to at the previous annual meeting had been further augmented during the year under notice, whilst the selling price of this class of goods had remained unaltered. He referred to the investment of a very large share of the Company's funds in other undertakings, principally an electric supply company in Victoria and in the Midland Electric Corporation. In regard to the operations of the Midland Electric Corporation, he regretted that manufacturers and others in the Midlands appeared to be not quite so up to date as their competitors elsewhere in their appreciation of the advantages to be derived from the use of electricity. Nevertheless, there was a growing demand, and he hoped that with improved trade there would be a great improvement in the future.

The report was adopted.

## NATIONAL ELECTRIC CONSTRUCTION.

The eighth ordinary general meeting of this Company was held at Winchester House on Monday, Mr. R. Stewart Bain, chairman of the Company, presiding.

In moving the adoption of the report and accounts (of which we gave particulars in our issue of the 17th inst.), the **Chairman**

Digitized by Google

commented upon the great progress as compared with last year, a £4,000 loss having been converted into a £20,000 profit. As regards the future, their prospects were distinctly favourable. They had just concluded two agreements, one for laying down an electric tramway in a town on the south coast, and the other for taking an electric lighting and tramway order in the Midlands, both of which they had every reason to believe would be very profitable, and which would occupy them for at least the next 18 months. In addition, they proposed to apply for powers for the extension of the Musselburgh tramways along the coast, and they had already applied for powers for making a new tramway between Edinburgh and Queensferry.

The report was unanimously adopted.

## MERSEY RAILWAY.

The half-yearly meeting of this Company was held last week at Worcester House, Walbrook, Mr. James Falconer presiding.

In moving the adoption of the report (of which we gave particulars last week), the **Chairman** said that substantial progress had been made during the half-year, both as regarded the number of passengers carried and the total receipts, and this was the more satisfactory seeing that the comparisons were now being made against receipts from electric traction, whereas former comparisons made at previous meetings were with receipts from steam traction. It was gratifying to find that the increases continued, and were due not to the novelty of the new method, but to the appreciation on the part of the public of the conveniences given by the Company. There was an elasticity about their system which rendered it capable of dealing with any traffic that might be looked for, and the chief thing necessary now was to popularise the line in the eyes of the public.

The report was adopted.

## PERTH (WESTERN AUSTRALIA) ELECTRIC TRAMWAYS.

The sixth annual meeting of this Company was held last week, Mr. Robert O. Ogilvie presiding.

The **Chairman**, reviewing the report (of which we gave some particulars last week), stated that, as compared with the previous year, the receipts showed an increase of about £7,000, of which nearly £6,000 was clear profit. The directors had every reason to anticipate that at the end of the present financial year they would be able to declare a dividend on the ordinary shares.

The report was adopted.

## BRUCE PEEBLES AND CO.

The report for the year ended Dec. 31 states that the net profit after making all necessary charges for the management of the business, including directors' and managing director's remuneration and auditors' fees, interest on debentures and income tax, amounted to £28,792. 7s. 6d., which, after adding the balance of £354. 5s. 1d. brought forward at Dec. 31, 1903, makes the available balance at the credit of profit and loss account, £29,146, 12s. 7d. The dividend on the preference shares, less income tax, for the half-year to June 30, 1904, was paid on Sept. 30, 1904, absorbing £2 856. 16s. 10d.; and the amount required for payment of the dividend on the preference shares, less income tax, for the half-year to Dec. 31, 1904, is £2,850. The directors recommend the payment of a dividend at the rate of 6 per cent. per annum on the ordinary shares in respect of the year to Dec. 31, 1904, less income tax, requiring £5,706. 5s.; placing to the preference shareholders' special reserve fund £2,870. 4s. 9d.; writing off preliminary expenses, £4,000; transferring to general reserve fund £7,000; and carrying forward £3,854. 6s.; together representing £29,146. 12s. 7d. The new works at East Pilton were completed in February, 1904, and the change has been very beneficial. The cost of the works stated in the original prospectus was estimated at £53,000, but owing to the expansion of the business the total expenditure under this head has been £93 000. The turnover for the past year has been more than double that of the previous year, and the orders on the books of the Company at the close of the year considerably exceed in amount those of the previous year. The Company have also several large profitable contracts on hand for power and traction companies. Owing to the considerable increase in the business of the Company, it is necessary that further capital should be raised. The shareholders will therefore be asked to sanction the creation of 10,000 additional preference shares of £5 each, and 10,000 additional ordinary shares of £5 each, and to increase the borrowing powers to the extent of £50,000. The further share capital will be issued as soon as possible, but it is not intended to exercise the new borrowing powers meantime.

## WILLANS AND ROBINSON.

The twenty-second half-yearly report to be submitted at the ordinary general meeting on April 5 states that the operations of the Company during the half-year have resulted in a loss, as regards the Rugby business, of £19,895. 1s. 4d., and as regards Queen's Ferry of £22,876 14s. 10d., or £12,771. 16s. 2d. in all. It is pointed out, however, that £18,954 1s. represents depreciation, and that £5,127. 2s. 9d. represents the valuing down of sundry stocks, etc., not arising directly out of the half-year's work. The total of these sums, £24,081. 3s. 9d., is in the nature of a "book" loss, and does not represent actual diminution of the liquid assets of the Company. As the debit balance brought forward amounted to £37,180. 6s. 11d., there is now a debit balance on the profit and loss account of £79,952. 3s. 1d. An endeavour has been made, in accordance with a wish expressed by shareholders at the last meeting, to apportion certain expenses between Rugby and Queen's Ferry. In some respects it has only been possible to do this by estimation. The directors have thought it right to exercise fully as great prudence in the matter of depreciation as in the times when the affairs of the Company were most prosperous. The extremely unfavourable trade conditions of the past year, leading to a reduction in prices unprecedented in the history of the Company, have resulted in a heavy loss even in the engine building section of the business. The directors are, however, glad to say that the steam-turbine business is developing rapidly, and promises to become a valuable speciality. A friendly arrangement has been entered into with Messrs. C. A. Parsons and Co., and the Company has taken a license enabling it to work under the patents of the Hon. C. A. Parsons. The Company has also valuable patents of its own under which it will continue to work. As regards Queen's Ferry, the attempt to find a purchaser for the business, or even for the works, has had no success, owing to the state of the trade. Work was necessarily carried on during the half-year, though under very great disadvantages, in order to complete existing contracts for boilers. Repeat orders, upon satisfactory terms, having resulted, the directors propose to continue the manufacture of tubes and boilers upon the present modest scale, in the hope that the business will grow to be self-supporting. This result may be contributed to by the steel manufacture, which, after being abandoned in May, 1904, was restarted at the beginning of the now current half-year, with every prospect, so far as can be judged at present, of proving profitable. The directors are satisfied that it is better under present circumstances to run the Queen's Ferry Works than to close them. Mr. T. O. Lazenby retired from the Board last autumn on account of ill-health. The vacancy has not been filled, and the Board propose that the number of directors, raised last year to seven, be reduced to five as before.

## FOLKESTONE ELECTRICITY SUPPLY.

The report for 1904 states that up to Dec. 31, 1903, the equivalent of 54,805 8-c.p. lamps was being supplied, but during the past year the equivalent of 64,915 8 c.p. lamps has been supplied. The revenue account shows a profit of £9,051, which, with the profits on installation work, etc., and £303 brought forward, and after allowing for interest on debenture stock, dividend on preference shares and bank charges, etc., and carrying £1,700 to depreciation fund, makes a net balance for distribution, after allowing for the interim dividend at the rate of 4 per cent. per annum already paid, of £2,058. The directors recommend a dividend at the rate of 7 per cent. for the half-year (making 5½ per cent. for the year), which will require £1,750, thus leaving a balance of £309, which it is proposed to carry forward. The profit in respect of the Hythe revenue account has been credited to the Hythe temporary lighting suspense account, reducing the balance on that account to £111. The sum of £1,557 has been written off in respect of depreciation of accumulators. It is proposed shortly to make a further issue of 4½ per cent. debenture stock, ranking with the £50,000 first debenture stock already issued. The stock will be offered in the first place to the shareholders and stockholders of the Company.

## W. T. GLOVER AND CO.

The report for 1904 states that the amount standing to credit of profit and loss account is £7,976, after adding £3,649 to reserve fund. The demand for goods of the classes manufactured by the Company (especially those for home consumption) has not shown any improvement during the period under review. The general financial position of the Company has improved, but the comparatively small demand above mentioned, and the severe competition existing, render it necessary for the directors to pursue a cautious policy. Accordingly they regret they do not yet feel justified in recommending the payment of a dividend. There is an increase in the item under the heading of investments due to payments made during the year, to which the Company was previously committed, and not to any extension of investments. The Company's rights and easements which were affected by the Bills promoted during the past year by the Trafford Park Estates, Limited, and the Stretford Urban District Council, have been satisfactorily protected, and the various points of contention amicably settled. A fund, as authorised at the last general meeting, has been created to indemnify the directors standing from time to time as guarantors for the fulfilment of the Company's contracts.

## BROMLEY ELECTRIC LIGHT AND POWER.

The report for 1904, to be submitted at the meeting on 3rd prox., states that the lamp connections have increased from 47,030 to 56,199. The sale of current has increased from £9,843 to £11,366. The result of the year's trading, including the balance of £35 brought forward from last year and after allowing for bad and doubtful debts, shows a profit of £8 286, and after payment of debenture and loan interest, etc., amounting to £2,527, the amount available for dividend is £5,759. An interim dividend at the rate of 4 per cent. per annum was paid for the half-year in October, and the directors now recommend a further dividend at the rate of 7 per cent. per annum, making a total dividend of 5½ per cent. for the year, that £1,800 be placed to the renewal reserve fund account, and that the expenses in connection with the new issue of capital, amounting to £24, be written off, leaving a balance of £85 to be carried forward.

## GREAT NORTHERN TELEGRAPH OF COPENHAGEN.

An approximate computation of the receipts and expenditure for 1904 gives net receipts of £480,000, which the directors will probably propose to distribute as follows: reserve and renewal fund, £56,000;

Digitized by Google

pension fund of staff, £8,000; remuneration to board of directors, £2,500; dividend equalisation fund, £53,500; dividend and bonus of 24 per cent. (5 per cent. of which has already been paid), £360,000; whilst the amount carried forward to 1905 will be about the same as was carried forward from 1903 to 1904.

## LIVERPOOL DISTRICT LIGHTING.

The report for the year ended Dec. 31 last states that the demand for electricity continues to increase satisfactorily, the number of units sold during 1904 being 246,943, as against 187,197 in 1903, and the amount received £5,384, as against £4,213 for 1903. The number of lamps supplied on Jan. 1, 1905, was 16,517, as against 14,000 in 1903. The directors announce that through a piece of great misfortune in the shape of bad debts, principally on the contracting business, it is impossible to declare any addition to the 2 per cent. dividend paid in August. They have thought it well to carry forward the small balance of £262, which remains to credit of profit and loss, and to write off the whole of the debt referred to, amounting to £1,879. The gross profit for the year amounted to £2,906, and with the balance brought forward from 1903 of £786 gives an available profit of £3,693. But for the misfortune referred to £2,142 would have been available for distribution.

## BUENOS AYRES AND BELGRANO ELECTRIC TRAMWAYS.

There is a balance on the year's working of £77,913. 13s. 10d., which, with the amount brought forward from last year (£2,479. 17s. 1d.), has been carried to net revenue account. After providing for the charges against revenue account and for the premium on £2,300 5 per cent. debenture stock purchased and cancelled, there remains a balance of £42,336. 0s. 11d. The 6 per cent. dividend on the "A" and "B" preference shares absorbs £20,250. An interim dividend of 1½ per cent. on the ordinary shares was paid in October last, and the directors now recommend a balance dividend of 2s. 6d. per share, free of income tax, or a total of 4s. per share, or 4 per cent. per annum, absorbing £20,000, and leaving a balance of £2,086. 0s. 11d. to be carried forward to next account.

## GUILDFORD ELECTRICITY SUPPLY.

The report for the year ending Dec. 31 states that the gross receipts were £4,859. 15s. 11d., as against £3,897. 7s. 7½d. for 1903. There is a balance on the revenue account of £1,848. 8s. 3d., after allowing £300 for depreciation, £200 for preliminary expenses written off, £150 for payment of a further instalment on the suspense account for law costs, and £119. 6s. in respect of depreciation on free wiring plant. After making provision for dividend on preference shares, interest on debentures, etc., the net revenue account shows a balance of £438. 14s. 2½d. for distribution. Out of this the directors recommend a dividend at the rate of 3 per cent. for the past year on the ordinary shares, which will require £403. 16s., leaving a balance of £34. 18s. 2½d. to be carried forward to next year's accounts.

## NEW COMPANIES REGISTERED.

**Mitcham Motor Company, Limited.**—Capital, £8,000. Objects: to carry on the business of vendors and factors of motorcars and other vehicles, whether propelled by electricity or other power, and to adopt an agreement between E. N. Læwer and A. W. Aitken of the one part and J. W. Collings on the other.

**Electric Ignition Company, Limited.**—Capital, £10,000. Objects: to acquire the business carried on by Constance Hall as the Electric Ignition Company, and to carry on the business of manufacturers of appliances of all kinds for electric ignition of internal combustion engines, manufacturers of electrical and mechanical appliances, electricians, workers of and dealers in electricity engineers, founders, etc. Registered office: Royal Wellington Works, Sampson-road North, Birmingham.

**Electro-Medical Supply Company, Limited.**—Capital, £6,000. Objects: to acquire the business of manufacturers of electrical medical battery apparatus and accessories, etc., carried on by J. Richert, E. I. Pronk, and A. E. Davies, at 22, Harp-lane, Great Tower-street, E.C., as J. Richert and Co., etc. Registered office: 61, New Cavendish street, London.

### Liens Registered.

**Llandudno and Colwyn Bay Electric Traction Company, Limited.**—Particulars of £60,000 debentures, created by resolution of Feb. 24, 1905, have been filed pursuant to Section 14 (4) of the Companies Act, 1900. Property charged: the whole of the company's undertaking and property (as a floating security). No trustees.

**Stanley Electric Carriage Company, Limited, Chelsea, S.W.**—Lien registered March 21, for £6,000 6 per cent. debentures. Holder: Major-General Sir E. H. Sartorius, K.C.B., Old Swan House, Chelsea-embankment. Charged on all the property, present and future, the undertaking, goodwill, business, and the uncalled capital for the time being.

**Light Cure and Electro-Therapeutic Institute, Limited, London, W.**—Lien registered March 20 for £540 8 per cent. debentures, part of £1,500 authorised. No trustees. Charged on all the effects and property, present and future, including the uncalled capital for the time being.

**Electrical Bleaching Company (1904), Limited, Manchester.**—Lien registered March 22 for £2,000 6 per cent. debentures, part of £14,000; amount previously issued, £12,000. No trustees. Charged on the undertaking and all the property and assets, present and future, except the uncalled capital.

## PERSONAL.

Mr. J. Mortimer, of Messrs. J. G. White and Co., tramway contractors, having received an appointment on the tramways at Cape Town, South Africa, was presented by the office staff with a shaving outfit, and by the workmen with a smoking cabinet and silver watch guard.

The Bermondsey Borough Council have appointed Mr. George Ingram, of Norwich, switchboard attendant, and Mr. A. B. Gundry, of New Cross, who has been engineer in-charge at St. Pancras Borough Council for three years, third engineer in charge at the electricity works.

The officials and employés of the Rotherham Corporation electricity works last week presented Mr. R. Jones, station superintendent, who has left to take up a position under the Southend-on-Sea Corporation, with a handsome case of drawing instruments and a large framed photograph of the electricity works staff. The case bears an appropriate inscription. There was also a silver matchbox, a present from Alderman D. L. Winter, J.P., the chairman of the Electric Light and Tramways Committee. Mr. E. Cross, the borough electrical engineer, made the presentation.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Manchester.**—The Corporation require tenders for switchboards. Tenders by April 4.

**Salford.**—The Corporation invite tenders for wiring their Seidley School. Tenders by 31st inst.

**Cartagena.**—The Public Works Department, Madrid, require tenders for electrification of the local tramways.

**Colchester.**—The Corporation require tenders for electric pumping plant and surface condensers. Tenders by April 5.

**Sofia.**—The District Finance Commissioners require 15,000 insulators, elements for batteries, etc. Tenders by April 3.

**Christiania.**—The Post and Telegraph Department require tenders for 8,000 kilos. of ¼mm. bronze wire. Tenders by April 10.

**St. Marylebone.**—The Borough Council invite tenders for the supply of house meters, including maintenance for two years. Tenders by April 4.

**Salford.**—The Corporation invite tenders for the wiring of the new Council school, Liverpool-street, Seedley. Tenders by March 31. See advertisement in last issue.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**French West Africa.**—The Governor-General of French West Africa, at Dakar, requires tenders for the erection and equipment of a central station at that place. Tenders by May 15.

**Brussels.**—The Government Railways require tenders for electric lamps and accessories in 21 lots. Specification No. 620 may be obtained from their Brussels office. Tenders by April 12.

**Bilbao.**—The Public Works Department at Madrid require tenders for the concession of an electric tramway in Bilbao, from the Calle de Hurtado de Amézaga to Plaza Circular. Tenders by April 24.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Utrecht.**—The Municipal Authorities require tenders for 20 electric motors for the tramways. Specifications may be obtained at 5s. from the Municipal Secretary, Town Hall, Utrecht. Tenders by 2 p.m. on April 8.

**Nuneaton.**—The Electricity Committee of the Nuneaton and Chilvers Coton Urban District Council invite tenders for the supply and delivery of cables and joint-boxes. Tenders by April 10. See advertisement.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station. Specification No. 619 may be obtained from the Government Railways Office, Brussels.

**Glasgow.**—The Trustees of the Clyde Navigation invite tenders for electric power generating and lighting plant for Clydebank Dock. Specifications, etc., may be obtained from Mr. T. R. Mackenzie, 16, Robertson-street, Glasgow. Tenders by April 17.

**Batley.**—The Corporation invite tenders for tramway extensions—viz.: (Contract No. 14) permanent-way construction and paving; (15) overhead equipment, steel poles, etc.; (16) feeder cables, conduits, and accessories. Tenders to the Town Clerk by April 17.

**Birmingham.**—The Tramways Committee invite tenders for supply, delivery, and erection of 200 electric tramway cars. Conditions, specifications, etc., can be obtained from Mr. Alfred Baker, general manager, 254A, Corporation-street, Birmingham. Tenders by April 4.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Hammersmith.**—The Council invite tenders for the supply of boiler flues and economisers; high-pressure steam-pipes; high-pressure feed-water pipes; exhaust steam, feed-water heater, and circulating-water pipes; steam-valves and feed-water heaters; and coal elevator. Tenders by April 5. See advertisement in last issue.

Digitized by Google

**London, S.W.**—The London County Council invite tenders (a) for the manufacture, delivery, and erection of eight 500-kw. induction motor-generators for certain sub-stations in connection with the Council's electric tramways, and for the supply and delivery at the Greenwich electricity generating station of (b) general wiring material and (c) low-tension cables, cable boxes, etc. Particulars may be obtained at the County Hall. Tenders by 10 a.m. on April 4.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

## RESULTS OF TENDERS.

**Todmorden.**—The Corporation have accepted the tender of Messrs. Venner and Co, Old Queen-street, London, S.W., for the supply of electricity meters.

**Poplar.**—The Borough Council have accepted the tender of the Stirling Boiler Company, at £1,950, for the installation of an additional boiler, etc., at the electricity works.

**Derby.**—The Tramways Committee recommend the acceptance of the tender of Messrs. W. Griffiths and Sons, London, at £18,689. 2s. 9d., for the construction of the permanent way and electrical equipment of the Kedleston-road and Walbrook-road routes, and that of the Brush Electrical Engineering Company, Limited, Loughborough, for the supply of four new cars.

**Kirkcaldy.**—The Town Council have received the following tenders for the extension of about 500ft. in length of the present East Pier:

| | | | |
|---|---|---|---|
| J. Best, Edinburgh | £32,562 | 19 | 0 |
| G. Lawson, Rutherglen | 40,629 | 18 | 0 |
| G. Smith and Son, Kirkcaldy | 38,777 | 19 | 8 |
| R. C. Crawford, Strathaven | 31,143 | 0 | 0 |
| G. and R. Cousin, Edinburgh | 51,729 | 17 | 0 |
| Tilbury Contracting and Dredging Company, London | 52,236 | 17 | 6 |
| Sir J. Jackson, Limited, London | 35,110 | 0 | 0 |
| Kirkwood, Kerr, and Co., Glasgow | 28,202 | 0 | 0 |
| Blair and Whyte, Bath-street, Glasgow | 27,858 | 16 | 6 |

| C. Brand and Son, 65, Renfield street, Glasgow (accepted) | 25,991 | 19 | 7 |

# BUSINESS NOTES.

## TRACTION.

**Pudsey.**—The work of widening the streets in preparation for the trams has been commenced.

**Croydon.**—A motion to rescind certain tramway extensions decided upon by the Corporation was lost.

**Kirkcaldy.**—The Scottish Parliamentary Commissioners have passed the preamble of the Kirkcaldy and Leven Tramway Bill.

**Unopposed Bills.**—The Metropolitan Railway and the West Cumberland Tramway Bills have appeared in the unopposed list.

**Belfast.**—The Corporation have received an intimation from the solicitors for the arbitrator that the award is ready to be taken up.

**Electric Tramway Trust.**—It is reported that an American syndicate is attempting to form a trust of the electric tramways in Toronto.

**Chester.**—After considering the question of motor 'buses, the Corporation have decided to proceed with the electric tram extensions at a cost of £17,000.

**London United Tramways Company.**—The London United Tramways (Extension of Time) Bill has been read a second time in the House of Commons.

**Mansfield.**—The promoters of the light railway scheme have abandoned the proposed additions to same, the terms of the local authorities being too onerous.

**Cheltenham.**—The extensions to the light railway were examined on Tuesday by Major Pringle on behalf of the Board of Trade. The inspection proved quite satisfactory.

**Maidstone.**—An enquiry was held by the Light Railway Commissioners last week into a proposed light railway between Headcorn and Maidstone. After evidence had been taken the matter was adjourned until April 10.

**Aberdare.**—The Urban District Council's Tramway Bill was before the House of Commons Committee last week, when the application of the gas company for a *locus* was disallowed. The Great Western Railway have withdrawn their opposition.

**Paisley.**—The Town Council of Johnstone has received an intimation from the Paisley and District Tramway Company that they are prepared to meet the Council relative to the extension of the tramways from the centre of the town to the boundary of the burgh.

**Ackworth.**—The enquiry by the Light Railway Commissioners into the Ackworth and North Lindsey light railway scheme came to a somewhat abrupt termination, the Commissioners holding that the magnitude of the proposal rendered it a case for Parliament.

**Anglo-Argentine Tramways Co.**—The directors, after transferring £10,000 to the reserve fund and £25,000 to the renewals fund, recommend a final dividend on the ordinary shares of 5s. each, making 8s. per share, or 8 per cent., for the year, carrying forward £5,922.

**Southend.**—A 10 minutes' service with three truck cars has been substituted on the Southchurch section for two bogie cars in a 15 minutes' service. The result has been highly satisfactory, as the traffic returns for the past month averaged 7·72d. per car mile against 6·72d. last year.

**Blackpool.**—The summary of traffic on the Corporation tramways from April 1, 1904, to March 16, 1905, as compared with the corresponding period in 1903-4, shows a large increase in the receipts, the total amounting to no less than £6,228. 10s. 1d. The Promenade and Lytham-road route was especially remunerative.

**Matarieh (Egypt) Railway.**—It is reported that the electrification of this railway, over which there has been some delay, may very shortly be taken in hand by the Egyptian Government, and a call for tenders may be expected. It is now suggested that, starting from Cairo, a line shall be constructed to the Matarieh Oasis *via* Abbas-boulevard.

**Overcrowding.**—In the House of Commons, the Chief Secretary for Ireland stated, in reply to a question, that the Dublin United Tramway Company's by-laws exempted children under three from fares, that he was not aware of any statutory prohibition against the levying of full fares for children under 12, and that the police were instructed to enforce the by-law against overcrowding.

**Wolverhampton.**—According to statements in the local Press, mud has been allowed to collect on certain sections of the tramway system to such an extent that the rails are invisible, with the result that an extra quantity of current is consumed in ploughing through the accumulation. A trial has been made with a motor omnibus with the object of linking up the Penn district with Wolverhampton.

**North-Eastern Railway.**—It is expected that the Ponteland section of the North-Eastern Railway system will be opened for the conveyance of passengers about the beginning of May. A large quantity of goods traffic has already been handled. It is stated that the usual steam locomotives will open the passenger service. It has not yet been decided whether steam or electricity will be used at some later date.

**Swansea.**—In reference to the rejection of the Corporation's Bill by the House of Commons Committee, as reported in our last week's issue, it is hinted in the local Press that the company would not be indisposed to treat for an arrangement providing for the "pooling" of the receipts from all the tramways in the borough, and for the voluntary sale of the company's property to the Corporation—on the basis laid down in the Tramways Act of 1870—after about 35 years' undisturbed possession of the whole system.

**Llanelly.**—At a special meeting of the Urban District Council the chairman made the pleasing announcement that an agreement had been arrived at in connection with the scheme of electric light and traction, as the result of further interviews. The Council have now decided to withdraw their opposition to the Bill of the South Wales Power Company, the company agreeing to contribute £1,000 towards the costs already incurred by the Council. They had also agreed to a penalty clause, and met them on several other points.

**Accident.**—At Wood Green on Monday a car was descending a steep hill when the trolley left the overhead wire. The driver, the only occupant, applied the brakes, but they failed to act, and the vehicle made a tremendous pace down the hill. It jumped the metals, smashed a street lamp, and dashed into the brickwork adjoining a chemist's shop, which was seriously damaged. The driver leapt from the runaway car. Although the scene of the accident is a busy spot, no one was hurt. The front of the tram was wrecked.

**Leeds.**—It is reported that for the financial year just closed the Corporation trams show an increase in receipts of some £17,000, the total revenue being £295,000. The passengers numbered 64,223,666, against 60,739,234 last year. The expenditure has not yet been ascertained, but it is hoped that the profit will equal that of last year, notwithstanding reductions in fares. The mileage was 7,000,000 against 6,091,437 last year, when the receipts per car mile worked out at 10·94d., rather more than that for this year.

**Penny Fares.**—Marseilles had an experience last Sunday in tramway administration which may have some interest for some British municipalities. The suggestion was tried of running universal 1d. fares for the day as a social experiment. In one way it was a great success. About 30,000 more people used the cars than on March 19, 1904, and nearly all crowded into the suburban districts. In its financial results, however, the experiments suggests some reflections. The takings last Sunday, with an increase of nearly 30,000 passengers, and many more cars employed, were £68 less than on March 19 last year.—*Globe.*

**Live Rails.**—In the House of Commons last week Mr. Weir asked the Secretary to the Board of Trade whether he would notify railway companies contemplating electrification that they should obtain specific statutory power, in view of the fact that the North-Eastern Railway, who did not obtain such authority, and consequently did not have their line inspected by the Board, had had 28 accidents, five fatal, through contact with the live rail. Mr. Bonar Law replied in the negative, reiterating an earlier announcement on the subject to the effect that the Board could not compel a railway company to take the step suggested.

**Pneumatic Railway Signals.**—The North-Eastern Railway have completed the last section of the electro-pneumatic signalling apparatus which they have for some time past been installing at Tyne Dock. This system is likely to be extended to the network of

Digitized by Google

rails at the entrance to Newcastle Central Station. The cost is estimated at about £50,000, but the money is expected to be saved by the increased control over trains, and the saving in wages due to many fewer operators being required for the work. At Tyne Dock under the new system 169 levers do the work which formerly required 278, and the labour of moving them is greatly reduced.

**Tram Fatality.**—An inquest was held at Devonport upon a labourer named George Adams, who, while laying telephones in a trench underneath the tramrails, was stated to have been knocked down by a tram and so seriously injured that he expired from the wounds. The evidence was of a conflicting character, two witnesses stating that they did not hear any bell ring, while the driver asserted that he rang the bell and reduced speed. Mr. J. W. Endean, manager of the Devonport and District Company's tramways, said that if the deceased had been above the trench when the front of the car reached the spot, the trigger of the lifeguard would have been struck and the lifeguard would have fallen, but that did not happen. The coroner, in summing up, stated that the driver had given his evidence in a straightforward manner, and the jury returned a verdict of accidental death.

**Torquay.**—Representatives of the Dolter Electric Traction Company visited Torquay last week, and with the contractors were driven over the route of the proposed tramways, preparatory to laying down the first section. Delay has been caused by the non-arrival of the decision of the Local Government Board as the outcome of the recent enquiry into the application of the Town Council for a loan of £42,000 for the proposed new electric lighting and power station, from which, according to agreement, the Council are to supply the company with current for working the trams. Pending the receipt of this communication from the Local Government Board, the Dolter Company, desirous of making a beginning, are seeking to come to an arrangement with the Town Council to be provided with a temporary supply of current from the present electricity station. It is stated that the whole of the capital for the Torquay tramways has been subscribed, and that the shareholders wish to see a start made; but, on the other hand, the company's officials are averse to the laying down of £70,000 worth of plant in the town until they know whether they are going to get the necessary current.

**London County Council.**—As the street widenings required in connection with the construction of the tramways from the Tooting terminus to Wandsworth are nearing completion, the Highways Committee recommend a vote of £360,000 for the carrying out of the work. The length of tramway affected is approximately 17½ miles of single line, which on account of the character of the thoroughfares affected, and the fact that they run along a main traffic route to the centre of London, it is proposed to electrify on the conduit system. The Financial Committee conclude their report upon this proposal with the remark that "although this reconstruction involves a large outlay, it is not expected to result in any surplus after the debt charges have been met, at any rate for some years to come." The Highways Committee's recommendation proposes that tenders shall be invited. The receipts for the week ending March 18 amounted to £12,814 against £10,644, and for the period from April 1 the total was £638,045, against £496,134. The Stoke Newington Borough Council have followed the lead of Battersea, Camberwell, and Hackney in passing a resolution approving the County Council over-the-bridge scheme.

**Manchester.**—The elaborate scheme evolved by the Corporation for the conveyance of parcels is to be inaugurated on Monday. Parcels will be carried not only within the city and the area of Greater Manchester, but also dispatched to any part of the kingdom and abroad. During its preliminary stages the new department has been under the charge of a special sub-committee, but a permanent sub-committee has now been created. The general manager (Mr. J. M. M'Elroy) has prepared a handbook headed "Parcels Express," which gives a quantity of information as to the transit of parcels. There are receiving offices in all parts of the city, besides others in the suburban districts. Vans will call at each of the sub-depôts and receiving offices frequently during the day, and at warehouses, shops, or other places of business, for the collection of parcels, on application being made to the parcels superintendent at the chief office. Stamps for prepaid parcels may be purchased at face value in numbers of not less than 25. Within the area of Manchester and its environs a parcel not exceeding 14lb. in weight will be carried for 2d.; under 28lb., 3d; under 56lb., 4d.; and under 112lb., 6d. will be charged. A little more will be charged for collection and delivery beyond the city area. Special parcel-carrying cars are to run over the city system, and the ordinary passenger service cars will be used for the conveyance of parcels up to about 56lb. in weight. Messengers will deliver parcels up to about 28lb. in weight to any address within a reasonable distance of the depôt or line of route. A special feature of the scheme will be an express messenger service. Parcels not exceeding 14lb. in weight can be placed immediately in charge of special express messengers, who will take them to their destination if it is within half a mile of any of the Manchester tram termini or lines of route. For this service the charges are 6d. within one mile from Piccadilly, and 3d. for every additional mile or part of a mile. The conductors of the Corporation passenger cars will receive at any appointed stopping place written applications from the public for a van to call at any address within the prescribed area. The committee have also made arrangements to act as agents for all railway companies. This enterprise will be watched with much interest. The Electricity Committee have decided to appeal in the case of Midwood *v.* the Corporation, reported in our legal column. It is proposed to lay a double line to Chorlton-cum-Hardy at a cost of £10,000. The Improvements Committee have decided to inspect the route.

**Parliamentary Committees.**—Before Mr. Compton Rickett's Select Committee on Monday evidence was taken in regard to the Great Northern, Piccadilly, and Brompton Railway Bill, which seeks to authorise the company to construct an extension of the authorised railway from the Strand under the Thames to Waterloo Station. Mr. Yerkes stated that the Underground Electric Railways Company had spent £3 650,000 on the Great Northern, Piccadilly, and Brompton Railway, and hoped to be ready for the public in 18 months. Ninety-five per cent. of the tunnelling was completed, and contracts were about to be made for the rolling-stock. Replying to the chairman, witness said the capital of the company was £5,000,000, of which half was subscribed. They had, by profit-sharing notes, raised £7,000,000 privately, and had also sold £2 000,000 of securities. These profit-sharing notes were a kind of short debenture; those who advanced the money on them were entitled to half the profit if the shares were sold beyond a certain price. Continuing his evidence on Tuesday, Mr. Yerkes stated, in reply to a question, that to make two lines instead of one would cost £120,000 more. Between Holborn and Surrey-street, Strand, there would in any case be two tracks. The journey from the Strand to Waterloo Station would occupy about 1¾ minutes. After further discussion the chairman announced that the committee were unanimously against a single-tube railway. Sir Ralph Littler suggested that the Bill should be passed with a clause to the effect that the railway under the Thames should not be constructed unless the company obtained power for the laying of two tracks. The chairman replied that the committee would consider the proposal. Evidence favourable to the scheme was also given by Sir C. Owens, general manager of the South-Western Railway Company. On the matter again coming before the committee, Mr. Raskill, K.C., stated that the promoters had had the intimation of the committee under consideration, and they proposed to insert the following clause: "Provided that Railway No. 2 by this Act authorised shall not be opened for traffic unless and until an additional tunnel has been constructed so as to provide separate tunnels for up and down traffic." The committee accepted the clause. Mr. Baggallay, K.C., on behalf of the Thames Conservators, brought up a clause safeguarding their rights and interests in the bed and shores of the river and providing that the position and character of any piling, staging, or other works to be erected in the waterway in connection with the construction of the railway should be subject to the approval of the Conservators. This was agreed to. The committee found the preamble proved, and the Bill, as amended was ordered to be reported for third reading. In the course of the evidence Sir Douglas Fox gave it as his opinion that there would be no difficulty in working the section as a single line. In regard to the Edgware and Hampstead Railway Bill, by which powers are sought to effect a slight deviation of the railway so as to make a more convenient junction with the Charing Cross, Euston, and Hampstead Railway, and to extend the time for the completion of the works, clauses have been agreed with the London County Council and the Hendon Urban District Council, the only petitioners against the Bill, and the measure has been referred to the Committee on Unopposed Bills.

**The District Railway.**—This company dispatched their first electric train in the early hours of Tuesday morning from Mill-hill Park to Bow-road. Among those who took part in the trial were Colonel Yorke and Mr. Trotter (representing the Board of Trade), Mr. John Young, Mr. W. E. Soar, and Mr. King (respectively the general manager, the traffic manager, and the engineer of the District Company), Mr. Ellis (general manager of the Metropolitan Railway), Mr. Jones (electrical engineer of the Metropolitan Railway), Mr. Bullock (assistant general manager of the London, Tilbury, and Southend Railway), Mr. Chapman (electrical engineer of the Underground Electrical Railways Company of London, who has had charge of the electrical equipment of the system), and Mr. Wells, of the British Westinghouse Company. The train was made up of seven vestibule cars, propelled by six motors of 200 h.p., the whole covering a length of 350ft. The trial run was highly satisfactory, although there was a large amount of sparking due to the rust on the rail. Power is obtained from the Lots-road generating station at Chelsea, which transmits the current to 14 sub stations at various places on the line. The time occupied in covering the 12¾ miles from Mill-hill Park to Bow-road was an hour and 10 minutes, including a lengthy stop at Whitechapel to enable the party to inspect the sub-station there. In ordinary running the time occupied, including stoppages at each station, will be about one hour, a great advance on the nine miles an hour which is the scheduled speed of the steam trains. It is believed that the stops at each station need not average more than 20 seconds in lieu of the 35 which the trains are now scheduled to make. It is proposed to solve the difficulty of providing means to discharge passengers without interfering with those wishing to enter the train by making those desirous of alighting leave the car by a door in the centre, while passengers wishing to enter have to do so through the end doors. It is predicted that the electric trains will perform the journey around the Inner Circle, with 26 stops, in 50 minutes, a saving of 20 minutes as compared with the time occupied under present conditions. No final decision has yet been come to on the question of fares, but it has been long settled that the "zone" system is to be put into operation. When the company's Bill was before the Parliamentary Committee it was stated that between certain stations—possibly within the City area—penny fares would be retained. Elaborate precautions are being taken to prevent an outbreak of fire, and the lesson taught by the disaster on the electrical railway in Paris two years ago has been taken to heart. The whole of the sleepers consist of Australian hardwood, the carriages are fireproof, and all wood on the station platforms is being removed and replaced by granolithic. The platforms of the new stations from East Ham to Whitechapel are constructed of stone, and the woodwork of all stopping-places from Mark-lane to Sloane-square has already been taken away. At South Kensington and Earl's Court the work is in hand. The electrification of the Metropolitan Company's system having been completed, as recorded last week, the Inner Circle is now ready for electric operation, but as sufficient rolling-stock of the new type is not yet available passengers must wait a few weeks longer for a regular service of electric trains. An assurance having been given that all the old servants will be retained, the employés have decided to accept the amended terms of pay, but protest against two principles—(1) only one man in the motor-room; (2) the payment of Sunday labour at weekday rate.

Digitized by Google

## LIGHTING AND GENERAL.

**Henley.**—The charge for electric energy is to be reduced to 4½d. per unit as from April 1, 1905.

**Southport.**—It is estimated that the cost of laying the local telephone wires underground will be about £25,000.

**New Marconi Station.**—The Canadian Government have decided to place a Marconi wireless telegraph station on Sable Island. It is expected to come into operation by Aug. 1 next.

**Eastern Telegraph Co.**—The directors of the Eastern Telegraph Company have declared an interim dividend of 1¼ per cent. on the ordinary stock in respect of profits for the quarter ended Dec. 31, 1904.

**Whitwell.**—At the annual parish meeting a long discussion took place on the lighting question and proposed scheme of electricity, estimated to cost from £1,600 to £1,800. No definite resolution was passed.

**London Gazette.**—The partnership between Ralph Gooch Tyler and William Evan David Duncan, carrying on business as electrical engineers at 20, New Bridge-street, London, has been dissolved by mutual consent.

**Aberdeen.**—The last report of the Gas and Electricity Committee shows that in February the electric works had generated 421,120 units, as against 401,739 units for the corresponding month of last year, which contained 29 days.

**Paddington Electricity Exhibition.**—An exhibition of electrical appliances, organised by the Metropolitan Electric Supply Company, was formally opened by the Mayor of Paddington at the Paddington Baths, Queen's-road, on Saturday morning.

**Agency.**—Mr. Hilliard Stephens, A.M.I.M.E., A.M.I.E.E., of 39, Victoria-street, Westminster, S.W., informs us that he has severed his connection with Messrs. Mackenzie Bros., and has been appointed sole London agent to the Falkirk Iron Company.

**Pitlochry.**—Considerable interest is being taken in the renewed proposals for the introduction of the telephone to the district. Forty subscribers have been secured, and there is reason to believe that the trunk connection may be made by the end of July.

**Pontnewydd.**—The Llanfrechfa Upper District Council have granted an application of Messrs. Linton Bros., builders, Newport, for a supply of water to enable them to carry out a contract to extend the South Wales Electrical Power Company's station at Cwmbran, at a cost of £9,200.

**Carlisle.**—The underground telegraph cable to the North is now practically completed to Carlisle, and will be opened for public service shortly. The cables, which are of British manufacture, with all the latest improvements in telegraphy, are laid 2ft. below the surface of the ground.

**London County Council.**—On Tuesday it was agreed to lend the Battersea Borough Council £7,306 for electric lighting purposes, and the St. Pancras Borough Council £5,370 for electric light installation and meters. Various notices for extensions of mains in the metropolitan area were assented to.

**Southend.**—The electrical engineer in his last report states that during the month 12 consumers had been connected with the mains, with an equivalent of 618 lamps. One consumer, with 64 equivalents, had been disconnected. There were now 46,288 lamps connected to the mains, and 715 consumers.

**Trowbridge.**—It is reported that the attempts to fix a convenient day for the meeting between the Council's Electricity Supply Committee and Messrs. Seymour, Williams, and Co.'s representative to discuss the question of expenses already incurred in connection with the scheme have so far proved futile.

**Long Eaton.**—An enquiry has been held into the Council's application for sanction to borrow £5,500 for purposes of electric lighting. Mr. Frank Worrall, surveyor and electric light manager, said the total capacity of the existing plant was 13,600 8-c.p. lamps, and that the committee were in a position to double the output.

**Cromer.**—A six days' electrical exhibition is being held in the town hall, Cromer. The promoters are Edmundson's Electricity Supply Corporation, who, in conjunction with the Urban District Council, run the local electricity works. The proceeds of the exhibition will be handed over to the funds of the Cromer Cottage Hospital.

**Hastings.**—The borough electrical engineer (Mr. Ferguson) is experimenting with one of the Union Company's Luna arc lamps (dealt with in another part of this issue) for street-lighting purposes. We understand that Mr. Ferguson is full of confidence as to its advantages, one being that it takes less current than the other street lamps.

**Brighton.**—A letter recently appeared in the *Sussex Daily News* protesting against the nuisance caused by the excessive escape of steam from the electricity works in North-road, Brighton, and as a practical result a petition of about 330 residents and ratepayers has been forwarded to the chairman of the Lighting Committee asking for abatement of the nuisance.

**Guildford.**—The Town Council are about to borrow £2,996 for a water supply for domestic consumption to the highest levels in the extended area. The scheme includes providing and fixing of alternate plant consisting of either electric, gas, or oil power, coupled to three-throw ram pumps, equal to a capacity of 7,000 gallons per hour, estimated at £285. 10s.

**Macclesfield.**—The Board of Trade have granted an extension of the provisional order for supplying the borough with electricity at present held by the Corporation. The Board of Trade have intimated that if at Dec. 31 the Corporation are not putting their scheme into operation, the Board will then have to consider seriously whether they shall not revoke the order.

**A Telephone Curiosity.**—The first telephone erected in England for practical purposes was this week disconnected at Devizes (Wiltshire). It was constructed in 1879 from a description and illustrative sketches of the instruments contributed by Edison to the *Scientific American*, and connected the old town hall with the residence of Mr. A. Cunnington, the constructor.

**Manchester.**—The Special Telephones Committee of the Corporation have decided to recommend the City Council to petition Parliament against, as it seems to them, the undue haste with which the telephone agreement is proposed to be carried through, and to ask that the Corporation representatives shall be heard before the Select Committee to which the agreement is to be referred.

**Wigan.**—The cutting of the first sod in the preparation of land for the erection of a new mill by the Coppull Ring Spinning Company in the village of Coppull took place on Saturday. The mill will be 110 yards in length and 110ft. in breadth, and will be lighted by electricity. The cost of the erection is estimated at about £90,000. The architects are Messrs. Scott and Sons, of Manchester, and the contractors for the building are Messrs. Wrigley and Sons.

**Stock Exchange.**—The Stock Exchange Committee have appointed April 5 special settling day for Henley's (W. T.) Telegraph Works Company's further issue of 5,000 ordinary shares of £5 each fully paid, Nos. 35,001 to 40,000, and have ordered the said securities to be quoted in the official list. The committee has been asked to allow to be quoted in the official list the United River Plate Telephone Company's further issue of 12,000 ordinary shares of £5 each, fully paid.

**Bristol.**—A resolution has been adopted to the effect that in view of the proposal of the Government to acquire by purchase the undertaking of the National Telephone Company, it be an instruction to the Telephones Committee to consider and report to the Council as to the rates charged for telephone service by the company in this city, and in other cities and towns where competition exists, and as to the rates charged by the competing undertakings in such other cities and towns, and also to report to the Council regarding the terms of purchase.

**Dundee.**—The city electrical engineer, Mr. H. Richardson, has reported to the committee a new system he has devised for charging for electrical energy. While based on the maximum demand principle, it is different from the ordinary maximum demand system of charging, in that the charge representing interest and depreciation is varied with the maximum load of the consumer. The result is arrived at in tables for the convenience of the consumer in order to show what price per unit he would have to pay with a given consumption and a given maximum demand.

**Deeside.**—Last year's accounts of the electricity department have been completed, and the Council are this year £910 better off than they were last year. The electrical undertaking has proved very satisfactory. The working expenses were £2,370. 1s. 5d.; interest and repayment charges amounted to £2,810. 8s., both of which sums were received from the revenue. During the year 103 additional consumers were connected, which brought the total up to 620. The committee are now offering motor power for 1½d. per unit, and they are now just about to double their plant, which will meet the requirements for some time to come.

**Camberwell.**—The Council on Wednesday declined to accede to an application of the London Electric Supply Corporation for a map of their area prepared to be certified, because of the difficulties which might arise in the future in reference to the purchasing power of the Council. The Council accepted an offer of the County of London Electric Supply Company, Limited, to provide a stand-by supply of electric light to the Old Kent-road Baths at the rate of 3½d. per unit, upon the understanding that no gaslights for illuminating purposes are to be installed, except in the wash-house portion of the buildings, but that pilot gas fittings are to be allowed in certain parts.

**South Africa.**—The popularising of electric power, says the *African World*, is going on all over South Africa in a remarkable manner. The Durban Town Council have agreed, on the recommendation of the borough electrician, to reduce the tariff for electric power for motors to £5 per motor up to 5 h.p., and £3 per horse-power above that, the first 100 units per month to be charged 2d. per unit, the next 200 units 1¾d. per unit, and all units above 300 to be 1½d., the lighting tariff to be reduced by 10 per cent. on 8d. per unit to all who pay accounts within seven days of being rendered. It is also intended to introduce 6d. slot meters for small consumers, so that such consumers may be able to purchase light cheap, and save trouble with accounts and meter reading. It is intended to hold an international exhibition in Johannesburg in 1907. The Town Council have voted £2,000 towards the fund in connection with the visit of the British Association.

**Postal Telegraphists.**—The committee of the Midland centre of the Postal Telegraph Clerks' Association has been in correspondence with Mr. Chamberlain regarding the recommendations of the Bradford Committee, and he has consented to receive a deputation on the subject when he is in Birmingham at Easter. In a letter to Mr. Chamberlain, the secretary of the Midland centre of the Postal Telegraph Clerks' Association, Mr. Samuel Boden, said the increased wages could be granted by setting aside about 25 per cent. of the five millions of profit annually earned for the State by the postal workers. To this Mr. Chamberlain replied that he could not admit that the profits accruing from the working of the Post Office ought to be any criterion whatever of the wages paid. Those profits were really made out of the business done by the public, and were in the nature of taxation which should go to the Exchequer and relieve taxation generally. In Mr. Chamberlain's opinion the question of wages should be treated separately on its own merits. An appeal has been addressed to Mr. Austen Chamberlain, signed by 32 telegraphists in his constituency of East Worcestershire, urging that when the Post Office and Telegraph Votes on the Civil Service Estimates are taken, he will consider the possibility of supporting the claims of postal servants for the adoption of the Bradford Committee's recommendations. They also ask the Chancellor of the Exchequer to receive a deputation.—*The Times.*

Digitized by Google

**East Barnet Valley.**—The North Metropolitan Electric Power Supply Company having acquired the undertaking of the North Metropolitan Electrical Power Distribution Company, propose to include the Urban District Council's district in their Bill now before Parliament, under agreement with the Council. The Council have asked for a copy of the Bill before giving a decision.

**Hanley.**—The report for the tenth complete year of the electricity works shows that the revenue for 1904 amounts to £15,277, the working expenses to £8,384, leaving £6,892, making, with a balance of £195 from the previous year, £7,087 to be dealt with. Of this sum the committee recommended that £1,150 should be applied to the reduction of rates. The accounts have been adopted.

**Partnership.**—Mr. Arnold G. Hansard, consulting electrical engineer, of 53, Victoria-street, S.W., has recently taken into partnership Mr. Henry S. Watson. Mr. Watson, who has taken an engineering degree at Cambridge, has latterly, whilst with the British Westinghouse Company, undertaken the equipment of factories, shipbuilding yards, and blast furnaces for motor driving as his special branch.

**Pudsey.**—The Corporation have commenced laying cables for electric lighting and power supply, and the cables of the South Yorkshire Electric Supply Company have nearly reached the centre of the town. The erection of a new electric transforming station has now been started, and the application for a provisional order for laying electric tramways in Pudsey is expected to pass almost immediately.

**Boston.**—A communication from the Local Government Board with reference to the application by the Town Council for permission to borrow £20,000 for electric lighting, making various suggestions, and recommending the appointment of an electrical engineer, will be considered by the Electric Lighting Committee next week. We understand that the Local Government Board recommend an extended scheme.

**Bermondsey.**—The distributors in the Bermondsey-street area are the most loaded, and an expenditure of £1,213. 18s. has been agreed to for an extension, together with the amount of £64. 17s. 5d., being one-fifth of the amount of extensions to switchboard. The Finance Committee have been requested to present an estimate as to the cost of the whole of the feeders required in accordance with the decision of the Council.

**Hammersmith.**—The premises of 13 additional consumers, representing a maximum of 250 8 c.p. lamps, have been connected to the mains. Six consumers have been disconnected, and the present number of consumers taking current from the mains is 1,562. The Borough Council have decided to appropriate £3,000 of the profits made during the year from the municipal electric light supply to the reduction of the general estimates.

**Exeter.**—At the last City Council meeting Mr. Wreford, moving the adoption of the report of the Electric Lighting Committee, said it was not proposed to employ an expert to make a further test of the machinery at the new electric light station. (We understand the test is to be made by the Council's electrical engineer.) He added that the test proposed to be made would not affect that part of the electric light machinery which was made by Willey and Co.

**Bradford.**—One of the Corporation's electric lighting cables fused on Friday at the junction of Leeds-road and Vicar-lane. There was a slight explosion, but no damage beyond the displacement of a few paving stones. In the course of two or three hours a temporary connection with another cable was established. The new engine and generator which have been installed at the works were started by Mr. H. Hibbert, deputy-chairman of the Electricity Committee, on the 27th inst.

**Finchley.**—The Electricity Committee have prepared the following budget: Estimated revenue—Supply £6,500, meters £120, public lighting £1,820, miscellaneous £70; total, £8,510. Estimated expenditure—Generation £3,025, distribution £250, public lighting (attendance and renewals) £450, management £990, repayment of loans £3,241. 17s. 6d.; total £7,955. 17s. 6d. Estimated net profit, £553. 2s. 6d. The present estimate is based on an estimated average of 25,000 8-c.p. lamps.

**Ripon.**—At the last City Council meeting it was stated that it was the intention of one or two companies to apply for the powers, and, further, the Council had some information as to which of the companies was likely to get the powers. They were given to understand, however, that if the Corporation could submit a reasonable scheme, and would give some evidence of their determination to carry it through, such a scheme would receive priority of consideration, and the others would not have a chance.

**Edinburgh.**—The Edinburgh District Lunacy Board have approved of a report by Messrs. Buchan and Hogarth on the power-station machinery and electric plant for Bangour, which stated that it would be necessary to allow for approximately the equivalent of 2,497 lamps of 16 c.p. for the complete electric lighting of the asylum for 1,000 patients, in addition to some 38 motors for ventilating and power purposes throughout, representing approximately a total of 50 h.p. or 60 b.p. The probable cost of the whole works was estimated at about £15,000.

**Torquay.**—At the last Town Council meeting the town clerk, upon being asked for information concerning the loan of £42,000 which had been applied for for the proposed new electric light and power station, replied that the Local Government Board had required further information. Further than that he could say nothing at present. He had addressed a reply under the instructions of the mayor and the chairman of the Electric Lighting Committee, to whom this matter had been referred as an emergency committee. It was suggested that the letter from the Local Government Board should be read to the Council, but the mayor said he did not think it desirable.

**"Telac."**—A trade-mark stamped on an article is the best method of defeating attempts at imitation, as to copy a trade-mark is a punishable offence. Messrs. J. H. Tucker and Co., of Samson-road, Birmingham, have adopted this precaution as a protection to electrical engineers using their goods, and have registered the word "Telac." This word is derived from the initials of "Tucker's electric lighting accessories." The word will have an enormous circulation on electrical apparatus, and will serve as a security that the articles bearing it come from a firm that has done much to raise the standard of electrical accessories. The registration of this trade-mark is referred to in our advertisement columns.

**Birkdale.**—The lighting company, through their contractors, F. W. Smith and Co., are fitting up a number of houses and shops absolutely free of charge. The minimum charge for current has been also taken off. Consumers who adopt this method of lighting their premises are treated exactly as though they had paid for the fittings outright, the company deciding the approximate positions of the lights, so that in the event of a tenancy being changed the lighting positions will be suitable. The fittings which are supplied free are, we are informed, quite ornamental enough for all ordinary purposes, but consumers are given the option of having better fittings and paying the additional cost only.

**Chester.**—The Lighting Committee recently instructed the electrical engineer (Mr. Britton) to make a further report on his views as to where a reduction can be made in the cost of public lighting, to what extent it can be reduced, and the cost of effecting such reductions. Based upon the report, the Electricity Committee have made the following recommendations, which have been adopted by the City Council: "That it be recommended to the Council that (1) 23 arc lamps situated in Hough Green, Grosvenor-road, Nicholas-street, Seller-street, and Egerton-street be lighted one day a week only; (2) the unnecessary incandescent lamps to be taken down as and when they are required for new districts; (3) when parts can be used for repairs to other lamps, the three and four-way incandescent lamps be converted to ½-ampere Nernst lamps, and (4) the whole of the public lamps in the city be lighted with electricity, the committee being authorised to provide and lay the mains, and provide and fix the lamps and appliances necessary for the purpose (½-ampere Nernst lamps being adopted in the street, and 8 c.p. lamps in courts), at an estimated cost of £1,900, the total charge for public lighting to be reduced to a sum equivalent to a lamp rate of 5½d. in the £ (say £4,400)."

**Poplar.**—The Council will apply for a further instalment of £10,000 on account of the loan of £59,000 for extensions and additional plant approved by the Council in connection with the electricity undertaking. The London County Council have written calling attention to the undertaking given by the Borough Council to provide for renewals and replacements, during the currency of the loan on the electric light undertaking, of any of the plant or machinery provided with the proceeds thereof. It was pointed out that the Poplar undertaking had been established four years; up to March 31 last a sum of £187,946 had been borrowed, mostly for 42 years, and only £2,494 at March 31 last had been paid off the loans. Moreover, since March 31, 1904, the Borough Council had borrowed a further sum of £45 000 for electric lighting purposes. In these circumstances the Finance Committee regard the creation of a reserve or renewal fund as very desirable in the interests of prudent finance, and ask that steps will be taken to form such a fund. In consequence, it has been decided that a depreciation reserve fund, to reach at least £10,000—the approximate cost of one of the large generating sets—be formed by the transfer of £2,500 from the present profit balance of £6,892. 13s. 5d., and by the transfer to the fund of 2½ per cent. of the net annual revenue. This amount, calculated upon present revenue, is approximately £400 per annum. A site in Glaucus-street is to be purchased in view of the necessity for the extension of the electricity works at an early date.

**Kingston.**—The Town Council have adopted a report, including the following recommendations of the Lighting Committee: That Messrs. Nichols and Co. be informed that the committee are prepared to place an electric street lamp in Gloucester-road, near Homersham-road, upon that firm paying £3. 18s. 6d., and upon their undertaking to pay £3. 7s. 6d. per annum for the current consumed; that 12 electric lamps be authorised to be erected in King's-road and Fassett-road, under the direction of Alderman Clarke; that a charge of 7d. per unit be made for electricity consumed through penny-in-the-slot meters; that a number of lamps be erected in other streets; that the General Purposes and Finance Committee be requested to obtain a loan of £4,000 for electric lighting purposes, such amount being a further portion of the amount of £15,850 sanctioned by the Local Government Board; that the charge for electric incandescent street lamps be at the rate of £3. 7s. 6d. per annum per lamp, this to include the cost of painting. It was explained with regard to the change in the charge for current that this was done with the object of encouraging profitable consumers and discouraging those who were not. The committee had made forecasts that the change would cost £700, and that those gentlemen adversely affected would object, and both had been fulfilled. The broad result of the working last year had been that 389 people paid £790 less than they would have done had they been charged under the old scale, and that 86 people paid £136 more; £80. 9s. 5d. was paid by four people, and the remaining £55 was, therefore, divided among 82 persons. Several customers had threatened to leave them and go elsewhere. The Chairman said the question to be answered was, "Shall we suffer anything very serious by the loss of these gentlemen's custom?" He might say in reply to that they had for some time been experimenting in street-lighting, and they had now got a lamp that should suit them very well. The lamps in King's-road compared very favourably with the gas lamps in the neighbourhood, and his opinion, that the lighting in this road was better than when the gas lamps were in use, was confirmed by perfectly independent ratepayers. They also made a substantial profit out of them. If they lost the custom of a gentleman who averaged 4s. per lamp per annum, they could earn nearly 16s. per lamp for street-lighting.

## PROVISIONAL PATENTS, 1905.

MARCH 20.

**5782. Improvements in electric motor controllers.** The Electric and Ordnance Accessories Company, Limited, Robert Frederick Hall, and Joseph Richardson Garner, 24, Temple-row, Birmingham. (Complete specification.)

**5814. An improved automatic accumulator charging switch.** Hugo Hirst and Ernest Edward Stewart, 71, Queen Victoria-street, London.

**5820. Improvements in brush-holders for dynamo-electric generators and electromotors and other electric apparatus.** Electromotors, Limited, and John Henderson Hamilton, Louisa-street, Openshaw, Manchester.

**5821. Improvements in mercury vapour lamps (electro-thermo-mercury vapour lamp).** Joseph Skwirsky, 36, Newman-street, Oxford street, London.

**5827. Improvements in field systems for continuous-current motor electric meters and/or needle instruments.** Carl Wilhelm John Busch, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901 March 22, 1904, being date of application in Germany.) (Complete specification.)

**5829. An improved contact maker for electrical ignition devices and like uses.** George William Brindley and Sydney James Bale (trading as the Barnstaple Motor Company) and Stephen James Murphy, 10, St. George's-crescent, Liverpool.

**5834. Improvements in the windings of electrical machines.** Siemens Bros. and Co., Limited, Queen Anne's-chambers, Broadway, Westminster, London. (Siemens Schuckertwerke G. m. b. H., Germany.) (Complete specification.)

**5836. Improvements in or connected with electric glow lamps.** Ludwig Scholvien, 37, Essex-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 29, 1904, being date of application in Germany.) (Complete specification.)

**5863. Improvements in electric train signals.** Albert Walter Sullivan and William Renshaw, Palace-chambers, Westminster, London. (Complete specification.)

**5865. Improvements in the construction of conduits for containing electric cables and wires, and other wires, tubes, pipes, and the like.** Walter Hepworth-Collins, 17, Nicholas-street, Manchester.

**5866. Electrically-operated tubes or bulbs containing rarefied gas or vapour.** Franklin Wise Howorth, 47, Lincoln's-inn-fields, London. (The Moore Electrical Company, United States.) (Complete specification.)

**5882. Manufacture of lithopones by electrolysis of sulphates or chlorides of soda and consecutive production of caustic soda.** Jean Baptiste Candau and Auguste Candau, 65, Chancery-lane, London.

**5887. Improvements in the electrolytic manufacture of copper wire, strip, or the like.** Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

MARCH 21.

**5896. A magnetic automatic motor.** Thomas Graiger, Oak Tree, Bogerstone, Mon.

**5899. Improvements in electric motors.** Mather and Platt, Limited, Edward Hopkinson, and Julius Firth, Salford Ironworks, Manchester.

**5918. Improvements in electric batteries and in electrolytic processes and apparatus.** Chamberlain and Hookham, Limited, and Sydney Holmwood Holden, 18, Southampton-buildings, Chancery-lane, London.

**5944. Improvements in means for controlling electric circuits.** Henry Leitner and Richard Norman Lucas, 4, South-street, Finsbury, London.

**5948. Improvements in or relating to incandescent lamp-holders.** William Winstanley Strode and William Edwin Halston, 111, Hatton-garden, London.

**5976. Improved means for regulating compensated series electric motors and generators.** The Elektrizitäts-Act.-Ges. vormals W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, April 5, 1904, being date of application in Germany.) (Complete specification.)

**5977. Improvements in connection with polyphase alternate-current electric machines provided with commutators.** The Elektrizitäts-Act.-Ges. vormals W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, April 15, 1904, being date of application in Germany.) (Complete specification.)

**5978. Improvements in and relating to methods of and apparatus for synchronising dynamo-electric machines.** The British Thomson-Houston Company, Limited, Hans Sigismund Meyer, and Paul Alphonse Mossay, 83, Cannon-street, London.

**5979. Improvements in articles made of granular materials, such as brushes for dynamo-electric machines, and in methods of manufacturing the same.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**5980. Improvements in and relating to alternating-current dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**5981. Improvements in and relating to alternating-current motors.** The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (The General Electric Company, United States.)

**5982. Improvements in means for protection against short-circuits.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**5983. Improvements in and relating to dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

**5984. Improvements in electrodes adapted for use in electric furnaces.** Edgar Field Price, George Emerson Cox, and James Gilbert Marshall, Clun House, Surrey-street, London. (Complete specification.)

MARCH 22.

**6052. An air suction contact device for stopping printing machines and the like by electricity.** Emil Wetzel, 15, Hamilton-gardens, St. John's Wood, London.

**6053. Improvements connected with electric lamps for illuminating timepieces and for other uses.** John Collard Vickery, 23, Southampton-buildings, Chancery-lane, London.

**6066. Improvements in or relating to electric clocks.** Frank Hope-Jones, 322, High Holborn, London. (Complete specification.)

**6067. Improvements relating to dynamo-electric machines.** The Phœnix Dynamo Manufacturing Company, Limited, Robert Pohl, and Felix Pohl, 322, High Holborn, London.

**6072. An electric lamp adaptor for oil, gas, or other luminant for motor, cycle, and other lamps.** Gilbert Davenport, 58B, Hatton-garden, London.

**6073. Improvements in electrical mercury switches operated by a vehicle passing along a railway.** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Akt.-Ges., Germany.) (Complete specification.)

**6077. Improvements in and relating to apparatus for indicating when the trolley standards of electrically-driven vehicles become "alive," and for guarding the standards when in such a condition.** Percival John Pringle, 323, High Holborn, London.

MARCH 23.

**6089. Improvements in magneto-electric generators.** Thomas William Stainer Hutchins, 17, St. Ann's-square, Manchester.

**6091. Improved means for laying telegraph and like poles.** John Riddell Brown, 55, Market-street, Manchester.

**6176. Improvements in and relating to relays for telephones, telegraphones, and the like.** Jens Herman Christensen, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**6192. Improvements in oscillographs.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

MARCH 24.

**6238. Insulating and acid-resisting sets, comprising of all metallic goods used for secondary batteries be vitreous enamelled.** A. Thomas, 45, Grosvenor-street, Pendlebury, Manchester.

**6245. Accumulator constructed of the pillar type of electrodes.** A. Thomas, 45, Grosvenor street, Pendlebury, near Manchester.

**6257. An automatic reverse-current safety throw-over switch for compound-wound traction generators.** Godfrey Bernard Parlett and George Howard Coxon, 36, John-street, Smethwick.

**6259. Improvements in apparatus for regulating the pressure in direct-current electric mains.** William Buchanan, Prince's-chambers, Wolverhampton.

**6267. Improvements in imitation candles for electric light.** Bernard Mervyn Drake, 66, Victoria-street, Westminster, London.

**6269. Improvements in systems of electric lighting.** Henry Leitner and Richard Norman Lucas, 4, South-street, Finsbury, London.

**6271. Improvements in pressel switches for electric lighting.** George James Bonnella and Arthur Bonnella, 40, Rosoman-street, Clerkenwell, London.

**6272. Improvements in and relating to vapour electric lamps and the like.** British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**6280. Improvements in and relating to telegraphic transmitters.** Joseph Theodor Szek, 22, Southampton-buildings, Chancery-lane, London.

**6286. Improvements in attaching insulators to tubular or like arms or brackets.** Siemens Bros. and Co., Limited, and George William Perry, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**6307. A new or improved unipolar cell and method and means of converting and/or transforming continuous currents of electricity.** Robert Grisson, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

Digitized by Google

MARCH 25.

**6324. An electric stethoscope.** Arthur David Evans and William Charles Snook, 8, Leadenhall-street, London.

**6337. Improvements in magnetic sparking plugs for internal-combustion and other engines.** John Arthur Torrens, Somerset, Coleraine, co. Londonderry, Ireland. (Complete specification.)

**6370. Improvements in the control of electric elevators.** George Andrew Philip Weymouth, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**6376. Improvements in means for regulating variable-speed dynamos.** Henry Leitner and Richard Norman Lucas, 4, South-street, Finsbury, London.

**6383. Improvements in electric switches having resistances.** Edmund Garside, 1, Queen Victoria-street, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published April 13.*

1904.

**6560. Automatic electric switches.** Atkinson.

**6646. Call system for telephone stations.** Ammer.

**7064. Mercury and other vapour apparatus for converting and obtaining light from alternating electric currents.** Holz. (Date applied for under International Convention, March 23, 1903.)

**7065. Transmitting alternating electric current through a vapour for rectifying or lighting purposes.** Weintraub. (Date applied for under International Convention, March 23, 1903.)

**7066. Alternating-current rectifying apparatus.** Steinmetz. (Date applied for under International Convention, March 23, 1903.)

**7067. Means for rectifying alternating electric currents.** Weintraub. (Date applied for under International Convention, March 23, 1903.)

**7298. Arc lamp electrodes.** Fleming. (Date applied for under Internation Convention, March 26, 1903.)

**7299. Arc light electrodes and methods of making the same.** Dempster. (Date applied for under International Convention, March 26, 1903.)

**7748. Switches for use in connection with electric lights and the like.** Chisholm.

**9517. Insulators for overhead electric conductors.** Richardson, Heap, Heap, Bailey, Brierley, and Billington.

**10073. Electric telegraphy.** Brown.

**10246. Vapour electric apparatus.** Carolan. (General Electric Company.)

**10460. Electric switches.** British Thomson-Houston Company, Limited. (General Electric Company.)

**11090. Electric switches.** British Thomson-Houston Company, Limited. (General Electric Company.)

**11444. Dynamo-electric machines.** British Thomson-Houston Company, Limited. (General Electric Company.)

**11545. Induction coils.** Gaiffe.

**11649. Incandescent gas, acetylene, and electric arc lamps.** Winkler.

**16985. Arc lamps.** Bermudez.

**20329. Telephone systems.** Young.

**22752. Method of and apparatus for transforming alternating currents of constant voltage and frequency into continuous currents of variable voltage.** Faget.

**25219. Protective systems for electric distribution lines.** Wilson. (Date applied for under International Convention, Nov. 20, 1903.)

**25608. Hertzian-wave projecting and receiving apparatus for locating the position of distant metal objects.** Hülsmeyer.

**26921. Electrodes for arc lamps and method of making the same.** Weedon. (Date applied for under International Convention, Dec. 10, 1903.)

**27063. Electric switches.** Bénassy. (Date applied for under International Convention, Dec. 17, 1903.)

**27861. Electric accumulators.** Gardiner.

## NOTES.

**New Publications.**—"Modern Electricity," by James Henry and K. J. Hora (London: Hodder and Stoughton. 5s.). The authors have compiled, in encyclopædic form, a concise and practical manual of the principles and applications of electricity. The volume should meet with appreciation from students and apprentices.

**Personal.**—We are informed that Mr. E. Guarini, who has frequently contributed information to our columns, has been appointed professor of electrical engineering at the technical school at Lima. We wish him every success in his new position, and hope that it will enable him to carry out more original work in connection with wireless telegraphy, for which there may be considerable scope in South America.

**Personal.**—We are glad to see that Lord Kelvin is making good progress after the operation performed upon him at the end of last week. The latest bulletin announces that the distinguished scientist is free from pain, and that his strength is well maintained. Several telegrams of enquiry as to the patient's condition were received from King Edward. Everybody will join in wishing his lordship a speedy and complete recovery.

**American Institute.**—We have received a copy of this association's *Proceedings* for March, which contain papers on "Line Construction for High-Pressure Electric Railroads," by Mr. G. A. Damon; "High-Pressure Line Construction for Alternating-Current Railways," by Mr. T. Varney; and "Track Bonding," by Mr. C. W. Ricker. There are also the discussions on "Acyclic (Homopolar) Dynamos," "Modern Central-Station Design," and "The Maximum Distance to which Power can be economically transmitted."

**Wireless Telegraphy.**—Reports have been current in the Press during the last few days to the effect that the Marconi Transatlantic system has been discontinued. According to a statement that appeared from Mr. Hall, the manager of the company, "long-distance" transmission for private messages has been suspended. It would be interesting to know precisely what is to be understood by this, as the Post Office does not now accept any Transatlantic ethergrams. It is stated, however, that the "ocean daily" will be published as usual.

**Electric Grain Elevators.**—The economy from electric power in loading ships with grain is illustrated by some tests lately carried out at Geelong, Australia. With three machines in operation for 8½ hours no less than 5,320 bags of wheat were handled on a current consumption of 42 kilowatt-hours. At 2½d. per unit the work cost 10s., a remarkably low figure for the quantity of material handled. It is estimated that a ship with a capacity of 20,000 bags of wheat can be loaded on this system for about £1. 15s., while if the elevation to the ship's side were not too great to allow of two or three bags being placed on the belt, the cost of energy would be brought down to little more than half.

**Institution Civil Engineers, France.**—No. 5 of the *Proceedings* of the Soc. Ingénieures Civils de France, just to hand, contains papers read at the March meeting. One is by Mons. P. Besson, on "Radium and Radioactivity," which is divided into the following sections: preparation of radium, the distinctive characteristics of the various rays, their physical, chemical, and biological qualities, and induced radioactivity. The other paper is by Mons. L'Ancel, and deals with high-frequency currents in wireless telegraphy. The next meeting will be held on April 7, when Signor Semenza will read a paper on the "Hydro-Electrical Installations in Upper Italy." There will also be a paper by Mons. K. Sosnowski on "Boilers and Steam-Engines at the St. Louis Exhibition."

**Pneumatic Tube Dispatch.**—According to a statement made in the House of Commons last week by the Postmaster-General, the Pneumatic Tube Dispatch Company's scheme does not stand much chance of seeing the light—if that term is permissible in the case of an essentially subterranean system—for the present. Lord Stanley is apparently unconvinced by the eloquent assurances of the company's engineers that the scheme could be consummated with a minimum of inconvenience to the public by means of the "cut-and-cover" method, which was employed in the construction of the New York underground railway. The scheme may, perhaps, stand in need of revision on certain points, as most of such schemes do, but it promised substantial advantages, and it is therefore regrettable that it should not have an opportunity of being discussed in committee. The system has been substantially a success on the Continent and in the States.

**Telephone Inspection Chambers.**—In the House of Commons last Friday Sir Thomas Dewar interrogated the Postmaster-General as to whether his attention had been called to a recent action to recover damages for personal injuries sustained through a gas explosion in a Regent-street telephone inspection chamber, and whether, having regard to the expression of opinion by the judge and jury, that the accumulation of gas in these chambers should be obviated by some system of ventilation, he would take steps to that end. In reply, Lord Stanley stated that he feared ventilation of the inspection chambers was impracticable, as local authorities were not likely to consent to ventilating pillars being fixed in the footways, and the owners of private houses would not allow him to carry pipes up the walls. Ventilating covers could not be adopted, because they would not keep the cables free from mud and water. He proposed to lay down certain precautions to be observed by the General Post Office staff when opening manholes in which the presence of gas is suspected, but he did not think that, so far as the facts were known to him, any precautions taken by the staff would have prevented the recent explosion in Regent-street.

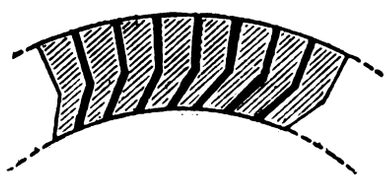
**Open-Air Telephony.**—America is admittedly progressive in matters telephonic, and the experience gained with the street-corner station shows that innovation to have amply justified itself. In all the cities and towns these stations are located at the corners of likely streets, and are stated to form a highly remunerative part of the business, as much as £50 per month having been collected from a single box. Besides this, they furnish an excellent advertisement, and the maintenance costs are light. The station consists simply of an ordinary private installation placed in a box and supported on a hollow iron post, through which the lines are led. No special wiring is needed. The Bell companies are especially enterprising in the matter of these boxes, which have been found of great utility for communicating with the fire brigade, hospitals, and the police. The boxes are keyless, and open on the handle being turned. There is a device on the gravity principle for payment, and the user, having called up the exchange and ascertained whether the desired connection can be had, deposits a coin in the slot according to the length of service required. It might appear as though the traffic would render it somewhat difficult to hear with an arrangement of this kind, but evidently our Transatlantic friends are not to be disturbed by such considerations. Still more surprising, these boxes, though easily opened, do not appear to have suffered from juvenile curiosity. This may be accounted for by the fact that

Digitized by Google

they are usually located in much-frequented places. These stations have the advantage over the public call offices in vogue here that they are accessible at any hour.

**Post Office Employes.**—The terms of the scheme propounded by the Postmaster-General for improving the conditions of service of certain classes of Post Office employés have been announced. It will be remembered that Lord Stanley was unable to accept the recommendations of the Bradford Committee, as these went beyond the terms of the reference. The leading feature of the scheme is the concession to all male telegraphists and sorting clerks aged 25 and over of an increase of 3s. a week in London and 2s. 6d. in the provinces, such increase to cease when the recipient reaches the maximum of his scale, the maximum itself remaining practically as at present. The maximum of the class of senior telegraphists in London, heretofore £160 to £190, is changed to £170 to £200; but no change is made in the corresponding class in he provinces, known as "clerks." The position and emoluments of the female staff both in London and the provinces are left entirely untouched by the new scheme. Male and female "learners" of over two years' service are given increases of pay averaging about 4s. a week, pending the elaboration of a scheme for improving the position of the class. Postmen both in London and the provinces are given small increases in pay and some other concessions. Lord Stanley's scheme was subsequently issued as a parliamentary paper, with an explanatory memorandum by his lordship. From this it appears that the female employees are not entirely ignored, as in London and the larger provincial towns their starting pay is to be increased by 1s. a week. The scheme is estimated to entail an increased expenditure of £224,400 for 1905-6, while in subsequent years the figure is expected to average about £372,300.

**Interlocking Commutator Bar.**—A new design of motor has recently been introduced in the States by Mr. James Burke, of Erie, Pa. A special feature is the interlocking commutator bar (shown in the accompanying illustration), of which a description appears in the *Electrical World* of New York. This is claimed to be the only construction which absolutely locks each bar to the bar adjacent to it throughout the length of the commutator, resulting in the perfection of commutator building and the prevention of irregular surface on the commutator, due to high and low bars and high or low mica. Such a construction is of great importance in variable-speed motors, where



the maximum speeds are often extremely high. Commutator troubles resulting in sparking at the brushes are not absent from ordinary motors, but with the usual motor construction they are accentuated when it comes to the extremely high commutator surface speeds of variable-speed motors. This motor is built for a speed variation of anything desired up to 4 to 1 as standard machines, and up to 6 to 1 as special machines. The entire speed change in all instances is produced by variation of the shunt field of the motors. This is accomplished by means of a drum controller, which also has the steps for reversing the motor, and which gives, when desired, the entire speed range in both directions.

**Over the Bridges.**—The voting on Mr. Whitmore's motion to omit the Embankment clause from the London County Council's Tramway Bill produced a result somewhat uncommon at St. Stephen's, a tie division occurring. Mr. Whitmore's arguments were pretty much what might have been expected; indeed, the subject has been debated so much in various quarters that little scope for novelty remains. He contended that better means of communication would be provided by the pending underground scheme, that æsthetic considerations should not be overlooked, and that it would, at any rate, be premature to sanction the proposal before the London Traffic Commission had rendered its report. Sir F. Banbury, in seconding, expressed the opinion that there was no need for an Embankment tramway, and little or no demand for one. Mr. Causton was ready with statistics in favour of the Bill. He stated that on Friday last, between 4.15 and 8 15 p.m., 930 persons took omnibuses over Blackfriars Bridge to join the trams, and that in the same time two cars left the terminus each minute, carrying 60 passengers apiece. That meant that 30,000 persons used the cars in four hours, and nearly the whole of them would be benefited if the tramway was extended over the bridge. It was no use waiting until the Royal Commission on London Traffic had reported, as that simply meant hanging the matter up indefinitely. He would like to see the Embankment made more useful. All the corporations south of the Thames, save Bermondsey, had petitioned Parliament in favour of the Bill. Mr. John Burns advocated the scheme on the ground that it would not only be a great convenience to the public, but would assist the distribution of traffic. He did not think motor 'buses would solve the problem, as they were larger, dirtier, and dearer than trams. After a few further speeches a division was taken, when it was seen that the efforts of the Bill's supporters had not been in vain, the figures being 171 each way. The Speaker gave his casting vote in favour of the "Noes," the effect of which is that the matter will go before a Select Committee preparatory to a final debate on the "floor of the House." Whatever one's opinion on this vexed question may be, it is as well that it should undergo detailed investigation in committee, as will now be the case.

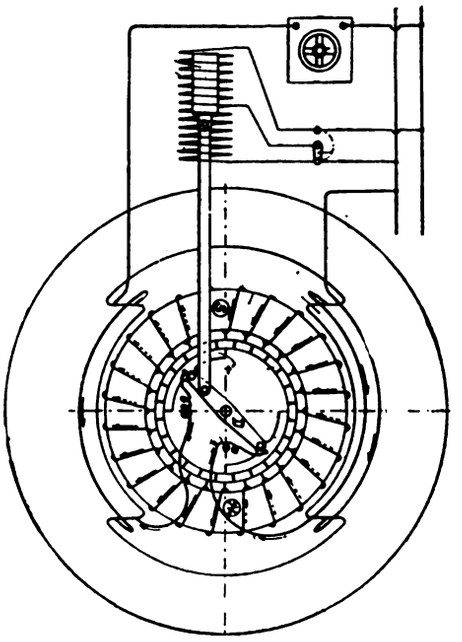
**Electrolytic Deposition.**—An abstract of an article by Messrs. A. Fischer and R. J. Boddaert upon the electrolytic deposition of the more important metals from moving solutions appears in the *Journal* of the Chemical Society. The ordinary electrolytic methods of estimation of several metals are compared experimentally with the methods using rapidly rotating electrodes, in order to discover how far the estimation can be shortened without sacrifice of accuracy. Except where otherwise noted, a matt platinum dish was used as cathode, and a disc of platinum making up to 800 revolutions per minute as anode. The best conditions observed are as follows—Nickel: Cold saturated solution of ammonium oxalate, 6 to 7 volts, 8 amperes. Time for complete precipitation, 40 minutes, temperature 20deg. to 60deg. Zinc: Good results are obtained with a solution containing sodium acetate and acetic acid, but the most satisfactory deposit was obtained from a strongly alkaline solution containing a little potassium cyanide. Five amperes and 5 to 5 4 volts were used, temperature 95deg., time required 20 minutes. Copper: Good results are obtained with any of the usual solutions; with a current of 5 amperes and working at 95deg., the precipitation is complete in from 10 to 30 minutes, according to the quantity of metal present. It is advisable to add ammonia when most of the copper is deposited and stop the current when the blue colour has disappeared. Bismuth: The metal is always deposited in a spongy condition, and trustworthy results cannot be obtained. Cadmium: Fairly good results were obtained by using a solution acidified with sulphuric

Digitized by Google

acid; with 5 amperes, 15 to 16 volts, and a temperature of 95deg., the metal is deposited in 10 to 15 minutes, only the last part of it being spongy. Lead: The deposition of lead at the anode in the form of the peroxide is complete in 15 minutes at 95deg., using 10 amperes and 3·5 volts. The precipitation is perfect. Silver: This metal is deposited from the solution in potassium cyanide with a current of 2 amperes and 4·5 volts at 95deg. in 10 to 15 minutes. The results are about 0·2 per cent. low. Mercury is deposited from a solution in nitric acid; the temperature must not be allowed to rise above 45deg., otherwise mercury is volatilised. Using 4 amperes and 5·4 to 6 volts, the deposition is complete in 15 to 20 minutes. Antimony: The metal was used in the form of thioantimonate, polysulphides being removed by adding potassium cyanide. The results were, however, always low, especially with quinquevalent metal, probably owing to some of the antimony going to the anode in the form of a complex anion. Tin: The results were similar to those obtained with antimony, probably for the same reason. In conclusion, the construction of a stand which permits the anode to be rotated and which has suitable electrical connections is described.

**Cantor Lectures.**—Mr. H. L. Webb delivered the last of his series of Cantor lectures at the Society of Arts on Monday last. He commenced by hinting that this lecture, unlike previous ones, might contain controversial matter, but that he was in the happy position of being able to say his say without being answered back. The efficiency of the telephone as regards time was discussed, and it was explained that a telegraph message took on an average one hour twenty-five minutes before the cycle of operations was complete, while a telephone cycle took two minutes forty seconds. Long-distance telephony was hardly comparable with telegraphy either as regards time or cost, because a three minutes' conversation was something so vastly different from any ordinary telegraph message; rather long-distance telephony might be compared to or was the rival of the railway. With regard to telephonic rates, the early pioneers started wrongly in taking the telephone as the unit and imposing a flat rate. The lecturer caustically referred to comparisons made by authors and speakers, deeming them very loose as regards accuracy and mostly unwarranted, neither the flat rate nor the telephone as unit, properly considering the various items making up the cost of the service rendered. The proper unit for charge is the message. Of course, the cost of the unit message varies with the prevailing conditions, and especially with area. A variety of methods of charging were mentioned to show that uniformity was still a long way off; thus at one place there was a flat rate pure and simple, at another a flat rate + cost of building line, at another a flat rate + cost of instrument, at another mileage charges, or, again, variations whether the subscriber was in business, or residential, and so on. The message-rate system was introduced as long ago as 1880, and might be said to have found general favour, but, like the flat rate, it had many variants; thus a flat rate + a charge per message, a charge diminishing with length of time of contract, diminishing with extensive usage, and so on. It is probably best to have a minimum rate. The early common action was explained as a co-operative system, and here were introduced a number of slides showing increasing complexity of apparatus due to extending a single station, to a number of exchanges each connected with the other by junction lines. Another condition often overlooked was that in installing a system the future must be considered, and the necessary provision for extension duly arranged. Not only the future but the changes at the present required due provision. Instances of actual work were given—in one case 20,000 changes took place with a net increase of only 5 500 subscribers; in another, 87,500 changes were made for a net increase of 37,000. Other cases were cited, and especially St. Petersburg and Tokio, where originally the installations were not well considered, for changes and future additions and accommodation to would-be subscribers could not be given. This series of lectures concluded with a hearty and well-deserved vote of thanks to the lecturer.

**Alternating-Current Motor.**—A patent has been granted in the United States to Mr. Robert Lundell for an improved alternating-current motor, which is described in the *Electrical Review* of New York. The invention relates particularly to that class of alternating-current motor which is furnished with a commutator and which may be operated from a two-wire circuit. The object of the invention is primarily to construct a motor which may be self-starting with or without load. Other objects are to provide a motor which may be quickly reversed from a distance without undue complication, which will give a great starting torque and a high efficiency, and which will

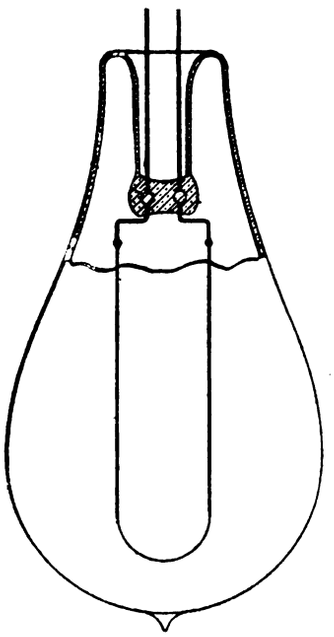


operate without injurious sparking at the commutator under various loads and speeds. Mr. Lundell's arrangement is based on the two principles that if a laminated field magnet is used in connection with an ordinary series-wound motor, the same may be made to run on a single-phase alternating-current circuit; and that an armature having a commutator can be made to run in an alternating-current field if certain coils in the said armature are short circuited upon themselves, though wholly disconnected from the primary circuit. Rotation of the partly short-circuited armature is effected by the secondary or the induced currents in the short-circuited coils. The motor consists of a field magnet connected with a source of alternating-current supply and an armature having a winding, the coils of which are connected to a commutator. Means are provided for causing two or more adjacent coils of the armature winding to become traversed by currents from a source of supply, while the remaining sections of the other adjacent armature coils are subjected to the effects of local currents which are induced in them by the field magnet.

**Incandescent Lamps.**—The question of a substitute for the expensive platinum connection between the filament and the leading-in wires of incandescent lamps has engaged

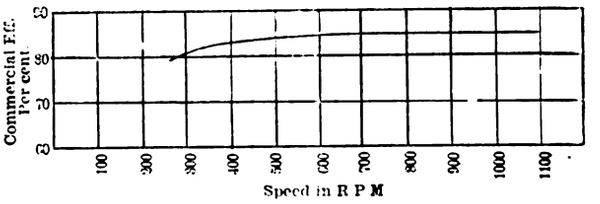
Digitized by Google

the attention of inventors from time to time, but hitherto without any definite result. It is claimed by Mr. J. H. Guest, of Brooklyn, N Y., that a device, which is described in the *Electrical World*, recently patented by him in the States provides a solution of the problem. From the accompanying illustration, it will be seen that a single conductor is used, one end serving as a filament terminal and the other for connection to the lamp base. As will be noted, that part of the leading-in wire which is sealed in the glass is stamped in such a manner as to introduce a ring into its length, the walls of which are highly attenuated and integral with the straight parts of the conductor. Since copper has about six times the conductivity of platinum, the part of the conductor which constitutes the ring can be made of much smaller cross-section than a platinum wire, and the cross-section of each side of the ring is reduced much more than half that of the wire itself, thus minimising the strain at heating and cooling. It is claimed that owing to the circular form given to the sealed-in portion, any strain due to expansion or contraction is not transferred to the integral straight portions of the conductor on either side. It is stated that some lamps constructed on this principle are still in good condition after burning over

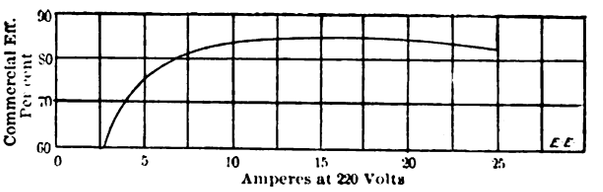


700 hours. Another advantage is claimed for this form of connection with respect to high candle-power lamps, in which two or more pairs of the connections may be easily sealed into the glass. As there are two paths for the current in the ring part of the conductor, and the conductivity is so much greater than that of platinum, the conductor used for a 16-c.p. lamp may be used for a 32-c.p. lamp. The outlay for material being negligible, and the manufacture involving a minimum of manipulation, the inventor's claim that the cost is only a fraction of that attaching to the usual method appears feasible.

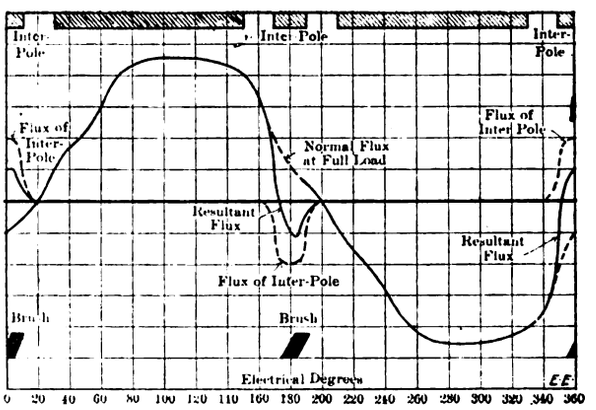
**Variable-Speed Motors.**—The use of auxiliary non-sparking poles to allow of a wide range of speed with shunt-wound motor has recently been referred to in our columns, and the subject is also dealt with in our "Questions and Answers" column this week. We take from the columns of the *Electrical World* of New York the following particulars from a factory at Bayonne, N.J., which has been electrically equipped throughout with motors of this type. It is claimed that variations in speed in the ratio of 1 to 4 are obtained without any sparking at the commutator. In the test of a certain 5-h.p. motor witnessed in the factory by the author of the article, the speed was varied between 275 revolutions and 1,100 revolutions, with a 100 per cent. overload, without any signs of sparking. The motor was then reversed, and the same results obtained without any alterations in the lead of the brushes. The illustrations given here show the efficiency of this motor for this range of speed, and also the efficiency curve for varying loads when run at 750 revolutions. The curve which gives the distribution of magnetic flux around the armature is also interesting, and shows the influence of these non-sparking poles in such a motor. Other curves given in the article show that the



motor had a good speed regulation for varying loads at any of the speeds for which it was designed to run. In order to secure this, however, certain adjustments had to be made in the lead of the brushes. It is evident that, by shifting the brushes from the neutral points, the magnetism in the auxiliary poles may be caused to add to or subtract from the total flux active in producing counter E.M.F.'s between the main brushes, and that thereby the machine may be given the speed characteristics of either a compound or a differential-wound machine. Obviously, with a given setting of the brushes away from the neutral points, the



magnetism introduced by the auxiliary poles will be of relatively a greater value compared with the flux of the main field poles when the latter poles are weak than when they are strong, and that the compound or differential effect will be greater the higher the speed. It is found that, in placing the brushes for a differential effect, it is possible so to adjust the angle from the neutral points that the increase of speed with the weakest main field may



be made just equal to the decrease of speed with the strongest main field, and that, for a certain main field strength, the speed is practically constant for all loads.

**Electrification of Railways.**—Mr. H. W. Wilson's paper before the Liverpool Engineering Society on the 22nd ult. dealt in a comprehensive way with the electrification both of suburban and main line railways. The paper contains a great deal of information which has been published before, but this information is collected together in a most convenient form for comparison. A good deal is

Digitized by Google

published about the single-phase systems of traction which are now on trial both in the United States and on the Continent. We notice also that comparative figures of cost for the electrical equipment of 60 miles of inter urban railway are given both for the direct-current system and for alternating current. The figures are those given by Mr. Blanck before the American Institute of Electrical Engineers, and show a saving of £395 per mile from the use of alternating-current motors. This saving is attributable to reduction in the sub-station costs and in the weight of the conductor used for the overhead line. We notice that Mr. Wilson calls attention to a somewhat striking example of the waste of electrical energy consequent upon large numbers of accelerations and retardations as exemplified in the case of the Liverpool Overhead Railway with the new equipment running on that line. "The overhead railway is 6½ miles long, and has 17 stations, averaging 620 yards apart. The time for the complete journey is 20·4 minutes, the average speed all through being 19 miles an hour. A stop of 11 seconds is allowed for at each station. Diagrams which have been published of trial runs on this line show that with an acceleration of about 4ft. per second per second, only 21 per cent. of the energy supplied is usefully employed in driving the trains, 50 per cent. of the energy supplied is wasted during the period of braking; about 11 per cent. is lost in the motor, and 18 per cent. in starting resistances and other minor losses. This is a somewhat striking result, and is due to no defect in the apparatus employed, but simply on account of the special conditions which have to be met. It shows also that the overall efficiency of the electrification of short-distance lines, where large accelerations and retardations are necessary, is not so great as might be anticipated." In this comparison we think the author is distinctly at fault in assuming that because 50 per cent. of the energy supplied is wasted in braking, that this 50 per cent. is not useful energy. The figures show that 71 per cent. of the energy supplied is used for accelerating and driving the trains, and the fact that a large proportion of this energy is afterwards absorbed by the brakes is due to the character of the service, and not to the fact that this service is electrical. We are inclined, on the figures given before us, to put the overall efficiency of the line at 71 per cent. The conclusions arrived at by the author are as follows: firstly, it is exceedingly desirable that if, and when, the electrification of lines other than short local lines, is decided upon, the various railway companies should agree as to the main principles which they decide to follow; secondly, methods of electrification which have been adopted up to the present for short local lines are quite unsuitable for main-line railways on the score of capital cost alone, apart altogether from the vital technical objections which could be raised; thirdly, the Board of Trade requirements as to the maximum voltage to be employed, and also a number of other points, required to be modified; and, fourthly, the necessity for the use of overhead conductors requires to be faced.

**Association of Municipal Corporations.**—A large gathering assembled at the Guildhall on Saturday, when the annual meeting of this association was held. The preliminary proceedings included the re-election of Sir Albert K. Rollit and Sir James Woodhouse as president and vice-president respectively. In moving the adoption of the report for the past year, which was carried unanimously, the president stated that their membership continued to increase, while the accounts showed a balance on the right side. Then Sir Albert plunged straight into the question of municipal trading. Their opponents were constantly repeating the cry of "Debt! Debt! Debt!" and seldom troubled to allude to the assets. These latter included not only actual profits in many cases, but an improvement in the health of the community. Profit-making, he reminded his audience, was not the primary purpose of a municipality, though, on the whole, they could show excellent results in this respect. It was not surprising, however, if young concerns, such as electric lighting undertakings, failed to show a large profit at first. The critics charged them with making inadequate allowance for reserve fund, renewals, repairs, depreciation, obsolescence, etc., which tempted him to recall Sir Edward Boyle Roche's "bull": "Why should we do so much for posterity, which has done so little for us?" We concur in the remark with which Sir Albert concluded this phase of the subject, that the equitable adjustment of such charges between the present generation and posterity provides a field for judicious statesmanship. Other points made by the president were that additional functions, such as education, had been imposed upon local authorities, while their power of raising the necessary funds was restricted by the practice of the Local Government Board in denying them fair terms for the repayment of loans. In this respect he thought the banks created under the Savings Banks Act might be a useful source of supply, besides which the fact of the money being used for municipal works would cause the ratepayer investor to take a closer interest in such affairs. He derided Government auditors as a panacea for the extravagance alleged against municipalities, but would welcome the appointment of professional auditors, as recommended by the Royal Commission on Municipal Trading, whose report had been ignored by the Government. One thing he hoped English municipalities would never descend to was subservience to trusts and "rings," such as was the case with some of the American corporations. The adoption of the report having been briefly seconded by Sir F. Powell, M P., it was agreed to unanimously. The meeting then addressed itself to the various resolutions on the agenda, which dealt with "police pensions," "elementary education," "telephones," and "trust investments." In connection with the last but one, the following resolution was proposed by "A Representative from Newport (Mon.)": "That the attention of the council be drawn to the proposed purchase of the National Telephone Company's undertaking by the Government, with a view to taking all necessary steps to safeguard the interest of municipalities in the matter." The mover intimated that the wayleaves payable to municipalities, the matter of inter-communication, and the reduction of tariffs were important matters for consideration. Alderman Southern, of Manchester, considered that the resolution should go a great deal further. Some active steps should be taken to secure to corporations the option of undertaking the local telephone service. Glasgow had demonstrated how advantageously this could be conducted by the municipality. He advocated prompt representations to Parliament before the agreement between the Government and the company came into operation "automatically." The subject, he knew, was to be considered by a Select Committee, but evidently Alderman Southern has no great confidence in such institutions. Besides this, he informed the audience that the Government's tenure of office was precarious, a General Election might intervene between now and Aug. 31, the date appointed for the agreement to take effect, and then, he implied, there would be little opportunity for the municipalities to ventilate their case. He thought they should at least take steps to present their views before the Select Committee. The original resolution was then submitted, and declared carried, when somebody discovered that Alderman Southern's remarks were not precisely equivalent to seconding it. However, the Mayor of Cardiff came to the rescue by formally seconding the resolution, which was then confirmed.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

*(Continued from page 439.)*

**Law of Double Winding Singly Re-entrant.**

A double winding which is to be singly re-entrant should retain a creep = 4, and yet have an odd number-pitch.

Such a winding is shown in Fig. 22. The number-pitch chosen is 5, while the winding naturally still obeys the formula:

$$w = p\,y \pm 2\,m,$$

$y$ being now an odd number.

The case is worked out for a four-pole machine so that $w = 24$.

It is quite similar to the armature in Fig. 13, and has similar disadvantages, chiefly arising from the fact that the two windings are not independent, and that, therefore, a fault in one means a fault in the other.

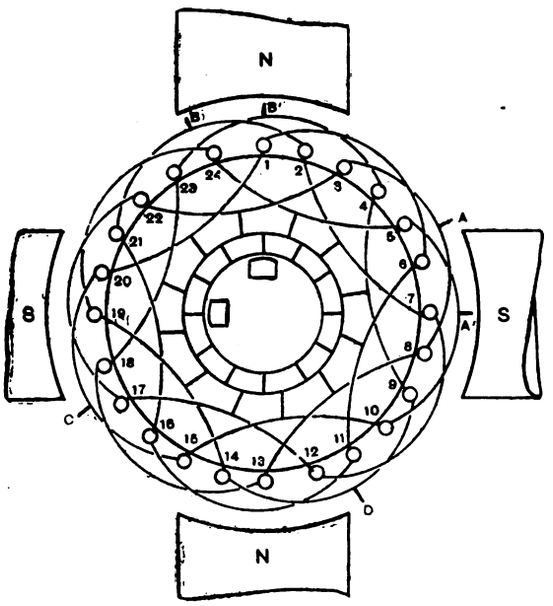

FIG. 22.

We see, then, that if in the general formula we write $m = 2$, while $y$ is an odd number, the winding remains duplex, but the re-entrancy is not double. This suggests that while the number of windings is settled by $m$, the re-entrancy is settled by the relationship between $y$ and $m$. As we look further into it we see that this is indeed the case; for if a winding be, let us say, triplex triply re-entrant, it must be possible to write its formula in either of two ways:

1. In the ordinary form—

$$w = p\,y \pm 2\,m.$$

2. As a multiple of the ordinary form

$$w = p \times 3\,\mathrm{K} \pm 2 \times 3\,n,$$

where K and $2\,n$ are the number-pitch and "creep" respectively of each of the simplex windings of which the triple winding is composed.

If we could not have written the formula in the second way, we should be forced to the conclusion that, although it was triple as given by its "creep," it was not triply re-entrant, because it could not be separated into three simplex windings; and this an example or two soon proves to be correct.

Thus the re-entrancy is clearly given by the highest common factor of $m$ and $y$, and it is useful to bear in mind the difference between two-circuit and multiple-circuit armatures in this respect; for the latter we found the re-entrancy was fixed by the highest common factor of $m$ and $\frac{w}{2}$.

Similarly it is quite possible to have an armature winding *quadruple* yet *doubly* re-entrant. In this case we know that $m$ will be 4, and the H.C.F. of $m$ and $y$ will be 2; such a winding might have a number-pitch of 22, and if it were for a six-pole machine we should have a choice of inductors as follows:

$$w = 6 \times 22 + 2 \times 4 = 140, \text{ or}$$

$$w = 6 \times 22 - 2 \times 4 = 124.$$

Either of these numbers of conductors might be used, according to which was the more suited to the nearest standard armature and to the electromotive force equation.

**Uses of Armatures with Re-entrancy not equal to $m$.**

The disadvantages of windings whose re-entrancy is not equal to $m$ has been referred to, and the question may naturally be asked, why are they then used? The answer is that the disadvantages are comparatively small, while with these armatures it is possible to make use of certain numbers of inductors otherwise impossible.

Take the case just quoted—viz., a quadruple winding doubly re-entrant for which we require either 140 or 124 inductors. The nearest number of inductors that we could possibly use, if the re-entrancy were quadruple (supposing the connections to be the same at both ends of the armature), is either 128 or 160, neither of which might suit the standard number of slots of the particular size of armature.

**Distinctive Uses of Two-Circuit and Multiple-Circuit Windings.**

Before leaving the subject of two-circuit drum windings, it may be well to refer to the question of when they should be used in preference to multiple-circuit.

This is a point which must be left very much to the discretion of the individual designer. Multipolar machines are at present becoming more and more the rule, as also are high voltages. In consequence, one would expect to see more and more of the two-circuit armature, and to a certain extent this anticipation is justified. The two-circuit armature is, on the whole, less liable to parasitic currents, and has the further advantages, in the case of small currents, of never actually needing more than two sets of brushes, and of requiring fewer inductors of larger section than the corresponding multiple-circuit machine.

On medium voltages it is a matter of individual taste: for low voltages the multiple-circuit armature has many obvious advantages, while for voltages of 500 and upwards the two-circuit armature is usually much easier to arrange.

Before giving a summary of the laws which govern two-circuit windings, we shall show how the same system may be applied to armatures of the ring type.

### TWO-CIRCUIT RING WINDINGS.

By a reversal of that process used in Part I. for evolving from the multiple-circuit ring winding the corresponding multiple-circuit drum, we may now from these two-circuit drums evolve two methods of arranging corresponding two-circuit rings.

**Long-Connection Form.**

It will be remembered that the method employed in the former case was that of removing the inner wires from the ring and placing them upon the outside of the armature. Similarly, now, we may

Digitized by Google

remove every other inductor from the outside of a two-circuit drum (say, Fig. 14), and let it form a return connection through the ring. We shall in this way obtain a ring armature of nine spirals (Fig. 23), in which the end of spiral No. 1 passes through the armature and is connected to the beginning of spiral No. 6, which in the old winding was inductor No. 11. The next connection joins the end of spiral No. 6 to the beginning of spiral No. 3, and so on round the armature until the winding naturally closes. The number of commutator sections, the position of the brushes, and the necessary number of these are all exactly as in Fig. 14. It will be noticed that the number-pitch is 5, *the same as for the corresponding drum*, and the number of spirals is odd. This type of winding is known as a long-connection series or two-circuit ring. It was, we believe, invented by Prof. Perry.

**Formula for Long-Connection Two-Circuit Ring.**

The formula which fixes the number of spirals for such a winding will obviously be half the number

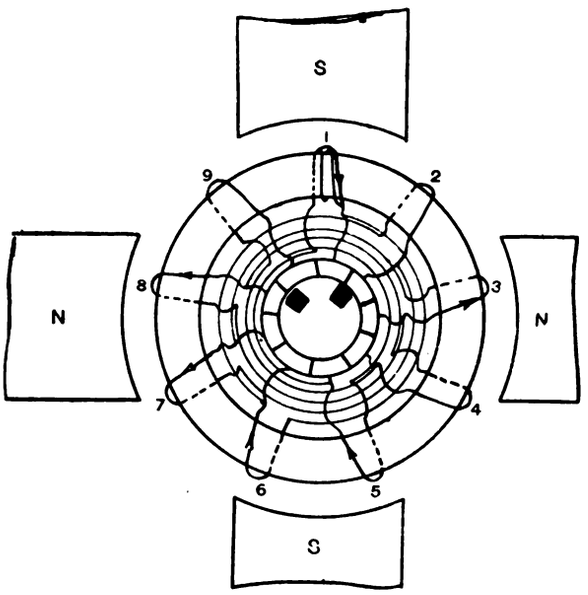

FIG. 23.

of inductors of the corresponding drum. Thus, instead of

$$w = p\,y \pm 2\,m,$$

we have

$$s = \tfrac{1}{2}\,(p\,y \pm 2\,m),$$

or since $y$ is not always divisible by 2, and, as has been shown, remains the same for the ring as for the drum, we may write

$$s = \frac{p}{2}\,y \pm m,$$

where $s$ = number of spirals, and $y$, $p$, and $m$ have meanings as before.

This formula tells us that if $\frac{p}{2}$ is an even number and $m = 1$, there will be an odd number of spirals on the armature; so Fig. 23, which is for a four-pole field, has nine spirals.

**Multiple Two-Circuit Rings.**

In the same way we may develop from Figs. 21 and 22 a double-wound two-circuit ring, either singly or doubly re-entrant, according to the corresponding drum. This is a useful exercise in interchanging ring and drum windings, but it is not of much practical value, since such armatures are very seldom met with. The simplex form as given in Fig. 23 with some modifications is, however, of considerable practical importance for reasons which we must now investigate,

**Advantages of the "Long-Connection" Two-Circuit Ring.**

In using the word "spiral" for a ring armature of this type, and in reckoning the number-pitch, we must not forget that each spiral, as numbered in Fig. 23, might (and in nearly all cases would) consist of several turns round the core, as shown in that diagram at 1; so that each spiral may really consist of a group, just as in the drum windings we have shown in Fig. 20 and elsewhere that each inductor may consist of a group. It will be noticed in Fig. 20 that when we have two groups on a drum armature, forming a coil, every turn of that coil has to proceed along both ends of the armature for some considerable distance. This necessitates a great deal of end room, besides not infrequently causing the close approximation of end connections between which exists a large difference of potential. Now, in the ring winding of Fig. 23 additional turns in series and forming a spiral (so long as the number of commutator sections is not increased) do not mean any additional connections passing from pole to pole at the end of the armature. Hence the winding would seem primarily suited to high voltages; and this is more marked if we consider the potential differences existing between neighbouring inductors in the cases of the drum and of the ring respectively.

Take as an instance of the former Fig. 14, and remember that each inductor adds a definite electromotive force to the circuit in which it lies. Upon counting up we find that between two neighbouring inductors (such as 17 and 18) we have the full potential difference which exists between the brushes. This means that neighbouring inductors must be very carefully insulated from one another, the more so since, as we remember, two-circuit windings are specially used for high-voltage machines. Thus between neighbouring inductors on a tramway generator we might easily have a potential difference of 600 volts.

Turning now to the ring armature of Fig. 23, we notice that the maximum potential difference which can possibly exist between neighbouring spirals, or groups of spirals (such, for instance, as 1 and 2), is that due to three groups—viz., 1, 6, and 2.

It is not necessary ever, upon a two-circuit long-connection ring winding, to have the maximum potential difference which exists at the brushes, as a strain upon the insulation between neighbouring spirals. Thus this form of ring winding is peculiarly suited to high-voltage work, and has been developed for this purpose of recent years. It is obviously both easier to insulate and less crowded at the ends than the corresponding drum. We must bear in mind, however (*a*) that all the end connections have to pass through the armature; (*b*) that a ring armature is never so good mechanically as a drum; and (*c*) that "former" winding is practically out of the question.

Since the chief advantage of these ring windings lies in the fact that they are easily insulated, they are more often used for high voltages than for heavy currents. This is also natural when we remember that the heavier the current that a given coil carries the more difficult is commutation; and ring armatures are always liable to give more trouble at the commutator on account of the fact that the turns are wrapped closely around an iron core, so that the self-induction per coil is considerable. This is the chief reason, then, why here we do not dwell at any length upon the various possibilities of multiplex two-circuit ring armatures.

*(To be continued.)*

## A NASCENT PROFESSION.

It was reserved to an American to give the up-to-date definition of engineering as the doing for one dollar of something that any fool could do for two. Central-station engineers, of all men, show forth in their practice the value of this dictum, for the rivalry between stations to show the lowest cost per unit generated is intense. But there is a corollary to this definition which has not been given due importance. It is that the one-dollar engineer must appeal to a larger public than the two-dollar fool in order to pay his way. Profits are relative; cost of existence is not far from being absolute. It is astonishing, therefore, that the subject of advertisement in connection with electricity supply undertakings has been to such a large extent neglected in the past. The recent action of the Croydon Council in establishing a publicity department, and the organisation by the directorates of one or two of the larger power schemes of efficient channels of advertisement, have at last shown us that a new profession is in process of birth.

The previous history of central-station advertising is conspicuous either by the absence or crudeness of method. Occasional electrical exhibitions were held, at which rival makers proceeded to revolve rival electromotors at rival stands, and to keep lists of prices and virtues of their wares, which they refused to anybody who could not show a trade card. At other periods the area of supply would be spasmodically deluged with more or less ineffectual literature, resulting possibly in a highly technical controversy in the local Press between the gas manager and the electrical engineer. Or what is known in religious circles as house-to-house visitation was indulged in by the corporation canvasser, sometimes with the lamentable result that an application form was filled in, and a supply promised, in a street where no cables were laid. To a great extent, efforts totally devoid of any system or economical management have been the rule, and the era of true commercial methods of selling what should certainly be regarded as a marketable commodity appears to have only just dawned.

It is a bold statement, but a well-authenticated fact, that among the general public judicious advertising makes as much, if not more, for success as sterling value of goods; it therefore follows that suppliers of electricity must not be content to rest only on the reputation for cheapness and steadiness that their commodity has acquired among their consumers, but also must take the proper steps to place before the remainder of the townsfolk the points which have formed the foundation of good repute. The adventitious aid which novelty first gave to the electric light has died away; electricity is as commonplace as gas. It therefore behoves the electrical engineer to push his wares in the same way that other business houses capture the market.

Why, for example, should not the borough electrical engineer, or one of his assistants, his publicity manager, keep shop? The Gas Light and Coke Company of London, for instance, have long ago realised the value of this method. A customer has not to wend his way to the gasworks, or to enter a building like a lawyer's office in order to pay his bill. He (or she, for it is often the lady of the house who looks after the gas) pushes open the glass door of what appears to be an ironmongery shop and finds within a perfectly affable and non-technical gentleman who will sell her a thousand cubic feet of gas or a cooking range with the same breeziness that a grocer's assistant pats a pound of butter into shape. Comparing this with the vaguely mysterious air of the electric works office, with its sliding scale of tariffs and the utter inability of the expert in charge to tell the lady what she will have to pay at the end of a quarter if she is careful, one cannot wonder that gas is often regarded as a commercial success and electricity as a scientific experiment. The only trouble is really that the business electric light engineer is a *rara avis*.

The principle may be applied further. There has not yet been seen, so far as we are aware, an advertisement in the general Press emanating from an electric supply company of anything like the eye-catching quality of those produced by the ordinary maker of jams or pickles. Yet it is an admitted first principle in business that persistent pushing of one's wares before the public eye is the surest way of getting business. Why should electricity be out of the running? It cannot afford to stand on its dignity. The method of house-to-house canvassing is good and effective so long as the advertising and executive departments work together. This is really the crux of the matter. Hitherto the interrelation of the business and engineering sides of the work has not been sufficiently recognised. The running of the plant has been entrusted to the trained engineer; the exertion of influence among the consumers has been left to non-technical men. The advance of the future will be made by men having three prime qualities: they must be engineers to the finger-tips, they must have an instinct for business, and they must be acquainted with all the ruses of modern advertisement in order that they may display their wares without obvious puffing. Their duties should be specialised into a department. They should direct the introduction of electricity supply to whomsoever it may concern; originate means to this end; supervise advertisements, canvassing, article and letter writing; exhibitions; meet business men on their own grounds; exert private influence where this is possible; and generally take the capabilities of the supply system on the one hand and the manifold needs of the consumers on the other, and mould them one to another. To men having a combination of the requisite qualities a new and lucrative profession is now opening out, for the reason that men of genius for this particular work are hard to get.

## DUNDEE POWER SUPPLY.

The Tramway Committee of the Dundee Corporation have now under consideration a proposed new system of charging for power supply which has been devised by Mr. Harry Richardson, the city electrical and tramways engineer. This he terms the Equitable system of charging for electrical energy. Through the courtesy of Mr. Richardson we reproduce herewith the explanation of the system, which he laid before the Tramway Committee recently. In his report on the subject, he draws attention to the fact that electricity supply stations have been built up to the present mostly for the supply of electric light. Owing to developments in the demand for power, the correct way to view the matter is to design a station and the distributing system for the purpose of supplying power, and then add such lighting as may be required. In this way the cost of power would become exceedingly low. Dealing with the maximum demand system, Mr. Richardson explains that as usually adopted it was not equitable, because it assumed that the standing charges for any consumer's maximum demand should be at the same rate per kilowatt independent of the magnitude of that demand. This point is dealt with in the explanation we print herewith. As regards the determination of the maximum demand, two optional courses are devised—either to take the rated power of the consumer's motors as his maximum demand, or to have a special maximum demand indicator fixed. Mr. Richardson suggests that the choice between these two courses should be left to the consumer. Then if the consumer overworks his motors, it would be advantageous to him to select the first alternative. On the other hand, if the motors are installed with an ample margin, the consumer would benefit from a maximum demand indicator. It seems to us that it would be more fair all round to have a maximum demand indicator installed in every power installation. The minimum price proposed for power supply in Dundee is 2½d. per unit, with reductions worked out in accordance with the formulæ we give below. In order to avoid any misunderstanding, the results have been tabulated by Mr. Richardson for a number of installations of different size. These will enable the consumer to see what his charge per unit would be for the given maximum demand and current consumption. The Tramways Committee have had this report before them, and have had it explained by their engineer, but the full consideration has been deferred until the members have had time to digest the information given. Mr. Richardson's explanation reads as follows.

## The Equitable System of Charging for Electric Energy.

The cost of generating electricity is made up of various items, of which the following are the most important: coal, water, stores, wages, repairs, management, rates, interest on capital, insurance depreciation, and sinking fund. It is obvious that some of these charges are nearly proportional to the amount of electricity generated, while others are to a great extent independent of that amount. These latter are called *standing* charges, while the former are *running* charges. *Standing charges* may be defined as the cost of being ready to run; *running charges* as the additional expense of producing the output. Going more into detail, the standing charges consist of: (1) all the capital charges (interest, depreciation, sinking fund, etc.); (2) rates; (3) insurance; (4) salaries of engineer and engineering and clerical staffs and establishment charges; (5) part of wages of generating staff; (6) coal necessary to keep boilers and pipes hot. The running charges consist of: (1) coal burnt to supply steam to engines (as distinguished from that required to make good radiation losses); (2) water; (3) oil, waste, and stores; (4) repairs; (5) additional wages for men over and above these required for standing-by plant in readiness to run it; (6) distribution losses, due to the resistance and leakage in cable.

For the financial year ending April 30, 1903, the total number of units sold was 2,609,718.

| | | |
|---|---|---|
| The standing charges were: | £16,400, | or 1·5d. per unit. |
| The running charges were: | 7,800 ,, | ·717d. ,, |
| | £24,200 ,, | 2·217d. ,, |

The capacity of the station is 3,000 kw., and since there are 8,760 hours per annum, the plant if run continuously fully loaded can produce 3,000 × 8,760 units = 26,280,000. The cost of doing this would be:

| | | |
|---|---|---|
| Standing charges: | £17,000, | or ·155d. per unit. |
| Running charges: | 78,000 ,, | ·71d. ,, |
| | £95,000 ,, | ·865d. ,, |

Thus, the total cost of generating electricity depends in a marked degree upon the proportion which the actual output bears to the total possible output of the plant. Put in another way: If the plant were working all the year round at its full capacity, each kilowatt of the plant would produce 8,760 units. In the year considered, each kilowatt actually produced 870 units.

The fraction $\frac{870}{8,760}$, or ·1, is called the *load factor*. It is frequently expressed as a percentage, as, for instance, in the above case, 10 per cent. In order to generate cheaply, then, it is necessary that the load should be as uniform as possible, and in order to keep it uniform it is needful to attract customers who have a "long-hour" load. Under the present tariff such customers are discouraged, an excessive profit being made off them, while the customers who occasionally make a large demand for a short time, but have a small total consumption (conditions which demand a considerable plant at the station generally standing idle), may actually be supplied at a loss to the corporation.

The use electricity is put to has nothing to do with its cost of generation, and it is quite illogical to charge different rates for electricity supply for lighting and power. The practice may, however, be justified on commercial grounds as a matter of policy, on account of the fact that motors generally give a long-hour load. But this is by no means always the case, and the method of charging is crude. The object of a tariff should be to make a uniform profit off each consumer. A change of tariff will not lead a consumer to constantly watch his meter and calculate the cheapest way of lighting his lamps. He will use the current as long as it is convenient for him to do so, and no longer. But the introduction of a sliding scale will attract new consumers whom it would not pay to use electricity under present rates. This is the argument on which is based the maximum demand system of charging. Underlying the whole argument is the assumption that the standing charges debited to each consumer are exactly proportional to his maximum demand. As a direct result the cost per unit to a consumer depends only on his "load factor," and not on the total quantity consumed.

For two consumers having the same load factor, but one consuming 10 units per quarter and the other 500, the cost per unit would be the same. Now, nothing is more certain than that the supply station would find it more economical to supply one large consumer taking 500 units per quarter than 50 small consumers all having the same load factor as the large one, taking 10 units each per quarter, and whose maximum demands all took place at the same time (as is practically the case in lighting). In other words, the *standing charges per kilowatt of maximum lamps* tend to decrease as the maximum demand increases. That this is so can easily be seen by the following considerations: the cost of the electricity meter, connecting a consumer to mains, the clerical work involved in reading the meter and sending in accounts, is nearly the same for a consumer having a maximum demand of ½ kw. and one whose maximum demand is 50 kw. Now to charge the latter 100 times as much as the former for the same thing is obviously unfair. But other components of the standing charges per kilowatt tend to decrease with increased maximum demand. Thus the attendance necessary on a 20-kw. plant would suffice for a 200-kw. plant, the capital cost, and therefore the capital charge per kilowatt of

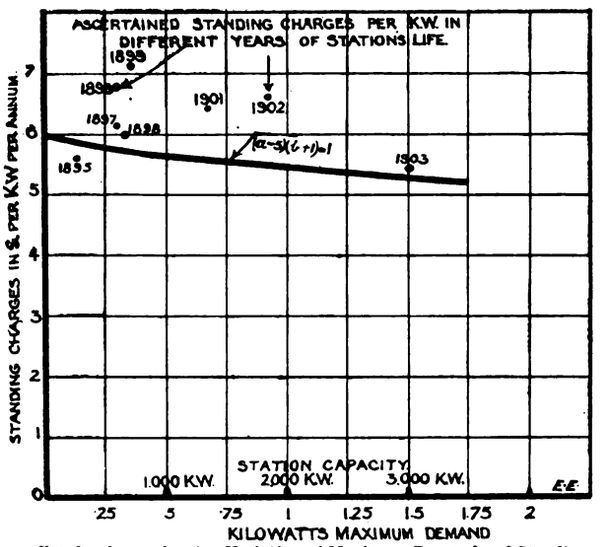

FIG. 1. Curve showing Variation of Maximum Demand and Standing Charges per Kilowatt at Dundee.

engines, dynamos, etc., decreases as their size increases, and the radiating surface of steam-pipes per kilowatt is reduced with increased output in kilowatts. In all the preceding comparisons between a small plant and a large one, the load factors of both have been assumed to be the same for clearness of argument.

The load factor is much more important than the size of the plant in fixing the generating and in consequence the selling costs. Thus a small plant with a good load factor can generate cheaper than a large plant with a poor load factor. But the above considerations indicate that, independently of the load factor, the size of the plant affects the generating costs, and as the plant necessary for each consumer is fixed by his maximum demand, the price charged him should depend in some way on the magnitude of his maximum demand. Mr. Wordingham touched on the relation of the standing charges to the output of the plant as follows: "The various items (of standing charges) enumerated are not actually proportional to the maximum demand in kilowatts. Many of them tend to diminish per kilowatt, as the size of the station increases, but they are all independent of the number of hours the demand is kept up."

*System of Charging — Fundamental Principles.*—Five pounds eight shillings having been found to be the average standing charges per kilowatt maximum demand in Dundee and the average maximum demand per consumer proved to be 1·5 kw., then it may be assumed that the true standing charge for a maximum demand of 1·5 kw. is £5. 8s. per kilowatt. But the standing charge per kilowatt of maximum demand increases with a less and decreases with

Digitized by Google

a greater demand. Now, calling $a$ = standing charges per kilowatt in £, and $b$ = maximum demand in kilowatts. Curve 1 assumes the true relation between the cost per kilowatt and maximum demand. Anyway, it fits the equation

$$(a-5)(b+1)=1, \text{ or } a-5=\frac{1}{b+1}, \text{ or } a=5+\frac{1}{b+1} \quad (1)$$

Then again let $c$ = total units consumed per quarter, $d$ = load factor, $e$ = running costs per unit in pence, $x$ = price per unit in pence (profit has not been considered, as it may be added to the formula). Now

$c = 2{,}190 \times d$, there being 2,190 hours per quarter . (2)

definition of $d$ being

$$= \frac{\text{real generation of units per quarter}}{\text{maximum possible generation in units per quarter}}$$

$$d = \frac{c}{2{,}190\,b}$$

or,

$$c = d \times 2{,}190\ b.$$

The standing charges charged to any particular demand would be £$a\,b$. To this must be added the running costs

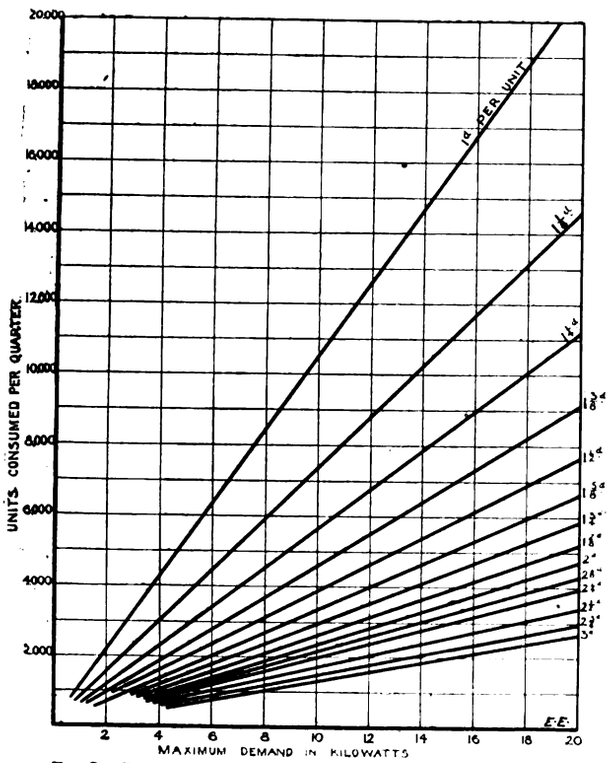

FIG. 2.—Curves connecting Consumption, Maximum Demand, and Price per Unit

per unit to make up the cost (total) of $c$ units (plus profit also). The price of a unit is therefore

$$x = \frac{60\,a\,b}{c} + e,$$

which gives price in pence, giving $c$ its value in equation (2), then

$$x = \frac{60\,a\,b}{2{,}190\,b\,d} + e \quad . \quad . \quad . \quad . \quad . \quad (3)$$

or,

$$\frac{60\,a}{2{,}190\,d} + e.$$

From (1) the value of $a$ may be got for any value of $b$, and then the cost per unit for any maximum demand and load factor may be got at from (3). The curves 2 and 3 accompanying show this applied to many conditions of varying load factors of 2 per cent., 2 5 per cent., 5 per cent., 10 per cent., 15 per cent., 20 per cent., and 50 per cent., and give the price per unit at these factors for any maximum demand from 0 to 100 kw. Taking another line of reasoning from the equation,

$$x = \frac{60\,a\,b}{c} + e.$$

Multiply by $c$, then $c\,x = 60\,a\,b + c\,e$, or $c\,(x-e) = 60\,a\,b$, then

$$c = \frac{60\,a\,b}{x-e.} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Now, by giving $x$ a certain value, an immediate relation is made between $c$ and $b$. For example, fix the price at 2d. per unit, then equation (4) gives

$$c = \frac{60\,a\,b}{2-7} = \frac{60ab}{13}.$$

$a$ is got from (1), so $c$ is easily determined for any value of $b$.

The above explanation and curves as given by Mr. Richardson are worthy of careful study. As the author states, the form of the equation is an equitable one, but the actual constants in the equation have to be varied to suit local conditions. It seems to us that the variation in the standing charge with the maximum demand should be somewhat larger than is given by Mr. Richardson's constants. These have evidently been obtained from average results with small consumers. It needs further experience with a considerable number of large power consumers on the system to ascertain how much the standing charge per kilowatt demanded can be reduced for

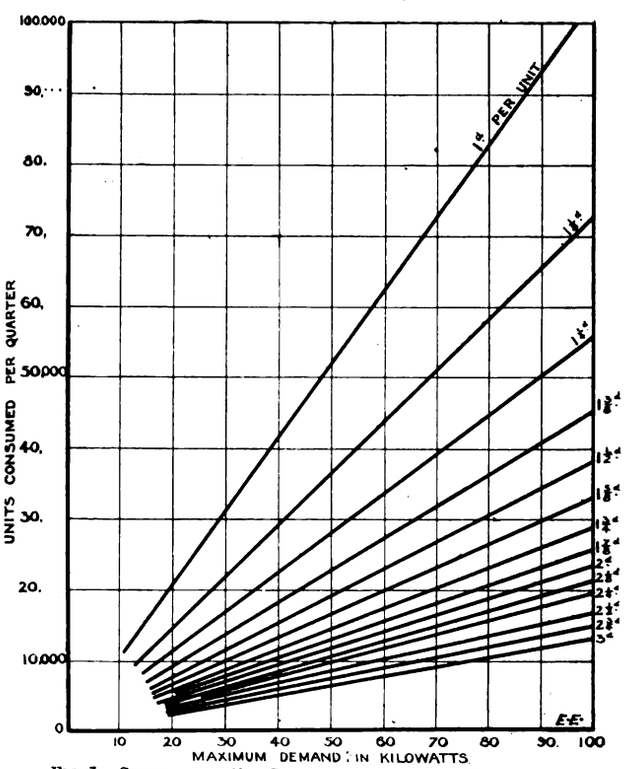

FIG. 3.—Curves connecting Consumption, Maximum Demand, and Price per Unit.

such consumers. Another point which needs to be borne in mind when considering any such scheme is the extreme difficulty of persuading the ordinary consumer of the equity of the maximum demand system of charging, unless he happens to be supplied at a low rate per unit by reason of his long-hour consumption. We wish Mr. Richardson every success in his attempt to reduce the price of electrical energy to power consumers in Dundee.

## APPLICATION OF ELECTRICITY TO INDUSTRIAL PURPOSES.*

BY J. F. C. SNELL, M.I.C.E., MEMBER.

(*Concluded from page 448.*)

### 2. THE COMPARATIVE ADVANTAGES OF DIRECT CURRENT AND ALTERNATING POLYPHASE CURRENTS.

As to the merits of direct current and alternating polyphase currents. The advantages of the direct current are variation of speed over a considerable range, without

* Paper read before the North-East Coast Institute of Engineers and Shipbuilders on Feb. 24.

Digitized by Google

undue loss of economy and with utmost simplicity; and in favour of the three-phase motor, the utmost simplicity of mechanical and electrical construction, the total enclosure of the motor, and absence of commutator and of any wearing parts other than the bearings, which are themselves negligible. The costs and weights of motors are in favour of the three-phase type. The starting and stopping are quite as easily and as economically carried out, and the only objection which one can offer to the three-phase motor is its less easy variation in speed when compared with its direct-current competitor. It is true that the pressure of 220 volts direct current is reputed to be safer to persons than 220 volts alternating, but as fatalities have occurred in both cases, and equally, as very many people, like the author, for instance, have had dozens of shock from both systems without harmful results, there is little to be said in favour of either one or the other in this respect. On the whole, therefore, the author is of opinion that the simple three-phase induction motor is much more likely to gain favour than even its quite simple direct-current rival. In point of efficiency, the direct-current motor has the advantage at present, and is probably, from physical reasons, likely to continue to have the advantage. The efficiencies of various motors of both classes are generally as given in the following table:

EFFICIENCIES OF ELECTRICAL MOTORS.

| Three-phase induction motor—220 v. | | | | Direct-current motor—220 v. | | |
|---|---|---|---|---|---|---|
| H P. of motor. | Speed. | Weight Lbs. | Efficiency Per cent. | High speed. | Weight Lbs. | Efficiency Per cent. |
| ¼ | 1,375 | 45 | 67 | 1,600 | 100 | 67 |
| ½ | 1,410 | 80 | 76 | 1,550 | 150 | 74 |
| 1¼ | 1,420 | 100 | 82 | 1,450 | 180 | 78 |
| 2½ | 1,420 | 150 | 83 | 1,320 | 280 | 80 |
| 3½ | 1,425 | 210 | 86 | 1,280 | 365 | 82 |
| 7 | 1,430 | 340 | 86 | 1,250 | 560 | 83 |
| 9 | 1,430 | 520 | 87 | 1,100 | 700 | 84 |
| 11 | 965 | 750 | 86 | 950 | 1,100 | 84 |
| 18 | 965 | 850 | 88 | 850 | 1,320 | 85 |
| 25 | 965 | 1,050 | 89 | 750 | 1,570 | 87 |
| 30 | 965 | 1,300 | 89 | 720 | 2,740 | 89 |
| 45 | 720 | 1,700 | 90 | 640 | 3,240 | 91 |

Particular works must, of course, require particular application, and as the author is able to speak quite disinterestedly, he strongly advises manufacturers to pay the small additional expense incurred by the fees of a recognised electrical expert to advise them upon the application of electricity to their machines. It is lamentable to find (as the author has several times found) that many of the economies which ought to be rightly obtained by the application of electricity, and by the initial expense which it necessarily incurs, are largely discounted by the absurd methods by which motors are applied to their work. In some cases lines of counter-shafting are retained, so as to group a number of sometimes quite large machines driven by one large motor, running often at less than half load, or, in other cases, fans originally running at 200 revolutions per minute are driven electrically at a much increased speed, and the necessarily increased power which the motors take up is a source of amazement to the manufacturer, who sometimes appears ignorant of the fact that as the speed increases, so the power required cubes. These are some of the practical mistakes which a professional consultant can and ought to be able to prevent. The adverse criticism which occasionally falls upon electrical driving, in the author's opinion, creates a real demand for experts of this class at the present juncture, when the tendency is so much towards the adoption of electricity as the driving agent.

The judicious grouping of motors or application of single motors to special tools, and the relation of their initial capital cost to the general working expenses after their installation, is in many works a complicated problem, upon which it is submitted only one who has made a special study of such applications is competent to advise. It would be unfair to the general industries of the country if, when called upon to make the necessarily great sacrifices in scrapping their original methods of driving, and substituting a more efficient electrical motor, every care were not taken to adopt at once the most economical method in outlay, and the most efficient in practice afterwards.

### 3. POSITION WITH RESPECT TO THE BOARD OF TRADE AND THE HOME OFFICE.

The regulations which are being imposed upon electrical users are somewhat confusing and complicated to the uninitiated, and the author thinks it will not be without use if he attempts to put concisely the obligations which users are placed under with respect to their employés by the regulations of the Board of Trade, and more particularly by the regulations issued under Section 79 of the Factory and Workshop Act, 1901, by the Home Office. A works skilfully changed by a competent adviser from steam driving to electrical driving would, necessarily, be protected on all these points. At the same time, the author does not wish to frighten manufacturers, and is of opinion that through the regulations being misunderstood many competent business men are chary of taking the step of changing over from one system to the other, believing that so many regulations imply that electricity is but an "infant" which has to be tenderly nursed, whereas in reality it has quite reached its maturity, so far as its application to machine driving is concerned. The regulations which appear to frighten the uninitiated will become as commonplace in the near future as the fencing in of belts or flywheels. There is no question that such regulations are both necessary and advisable.

First, the question of pressure. The limit of voltage which is imposed by the Home Office, and also by the Board of Trade, is 500 volts. That is the pressure of 500 volts between any two conductors, or 250 volts between any conductor and earth. The author is of opinion that 250 volts for engine works and shipyards is a sufficiently high pressure to adopt. It is a matter of common knowledge, especially with direct current, that if there be two conductors with a difference of, say, 250 volts between them, one of them (the negative) in course of time becomes approximately of the same potential as earth, due to dampness particularly, and to an electrical effect known as osmosis; and then, of course, the other becomes charged at a pressure which is 250 volts above the earth potential, and, therefore, a person touching the bare portion of such a conductor would obtain a shock at this pressure Such a shock, except under very special circumstances, is not in itself dangerous, but should there be in a shipyard, for instance, an electrical winch subject to all weathers, and a workman standing on very damp ground were to grasp the naked part of the "live" cable or part of the machine, he would get a very severe shock which might have even fatal results. But if such conductors be run through an iron pipe, or be surrounded by a lead sheathing, which is itself connected at points to water-pipes, or to other efficient earth-plates, it is an absolute impossibility then for any person to obtain a shock of any kind. Now the cost of running cables under these conditions is very little more than running them by other less thorough means, and as they are protected from so rapid a depreciation as will occur if they are open to all kinds of weather, it really is more economical to make a thorough job of this cabling at the time of the installation. The author regrets to say that too little attention is given to this portion of the work, and would urge upon manufacturers the necessity in their own interests of insisting upon good materials and a complete metallic protection of the cables.

Then take another portion which is operated by all classes of workmen—viz, the controlling switch and starting gear of each motor. Now, in the case of direct-current motors this consists of a simple switch containing many contacts, between each of which is a resistance coil, which is in effect the stop-valve of an engine, and permits the motor to start away easily, and without undue shock or stress; or in the case of a three-phase motor, the even simpler starting switch with its complementary auto-transformer, consisting of a two-way switch, on one side of which is connected a simple device for preventing a too big rush of current to the motor when starting from rest—a sort of by-pass valve—and which is put out of action by simply throwing over the switch when the motor has attained approximately its full speed. In both cases the handles of the switches should only be operative, or able to be touched by the workmen. The rest of the work should be screened by an iron shield, which should in turn be

Digitized by Google

metallically connected to the iron pipe containing the cables. This is really very simply done by merely making the end of the iron pipe secure to the casing containing the starting switch by an iron nipple. Then, too, as the motor contains the electrical circuit, any part of which may possibly, though very improbably, come into contact with the iron framework, it is necessary that the motor frame should also be connected to earth. If these three points be carefully observed, then it is absolutely impossible for any employé to obtain a shock. Moreover, in case of a fault in a cable, the fuse controlling that motor will blow, on account of the circuit made with the pipe, and, therefore, with "earth," causing a larger current to flow momentarily. The fault is then easily localised, and the machine restarted with a minimum loss of time.

The more care, of course, requires to be taken with respect to the lighting of workshops and offices, and particularly in the case of arc lamps in open yards. The author sees no objection in many cases to the use of overhead conductors, but then, of course, these will always be out of reach, and no harm can accrue from them. Where overhead conductors are used, however, it is advisable to guard against lightning strokes by fixing proper lightning arresters on the main controlling switchboard, so that, in the event of the line being struck, the discharge will pass to earth without breaking down the insulation of any of the machines on circuit at the time. Incandescent lamps should be swung from light gas-barrel or one of the many iron tubes now to be had, which would be in metallic connection with earth.

Some care is required in laying-out the cables for a large works, and a good deal of unnecessary money may be spent when such systems are not systematically and carefully worked out. Cables may be laid either too large, involving an undue capital expenditure, or too small, involving a too large drop in pressure. Subdivision is a very necessary factor, and it pays in large works to have a large switchboard controlling a number of individual circuits, each governing a group of tools. Tests ought to be insisted upon weekly, and the author suggests that a log book be kept, in which the daily readings of the meters will probably be kept, and which should also contain a record of the weekly tests. By this systematic method much annoyance may be spared the consumer, for weaknesses in any of the circuits are detected in time and put right, and consequent loss of time from machines lying idle will be averted. A simple testing arrangement, such as an ohmmeter and portable generator, costing under £20, will suffice, and is so simple in its application that an untrained boy can operate it and make the records necessary.

Alternating currents of the same nominal pressure as direct currents have to be more carefully guarded, for whereas the virtual or mean voltage is, say, 250, the actual maximum voltage is 250 $\sqrt{2}$, or 352 volts; so that a person getting a shock from an alternating-current circuit of the same nominal voltage as a direct-current circuit will be liable to a pressure of 40 per cent. more. Still, however, such liabilities can be made, and ought to be made, impossible, by adopting the simple expedient of a continuous metallic covering for all cabling, taking care to see that the covering is continuous, shielding the switches and starting gear, and earthing the motor frames. With these precautions there is not so much danger about an electrical system as there is from the belting of an ordinary countershaft. Any liability of fire is altogether removed in this way, providing that common-sense is exercised in guarding each circuit at the distributing switchboard by fuses or automatic cut-outs. Here, again, it is advisable to make these instruments "fool-proof" by having fusible cut-outs supplied with stamped standardised fuses; otherwise, if a motor develops a slight earth, or is overloaded at times and blows the regular fuses, there is too much tendency to put in a piece of copper in place of a fuse, with the result that any safety valve, as it were, to the system is blanked up.

The sooner manufacturers will agree in their own interests to adopt these simple precautions the better for the industry, and the less likely we shall be to undue visitations from Government officials.

4. The Importance and Economy of Standardisation.

There is only one more point to mention, but one by which a manufacturer starting to electrify his works can save a good deal of capital outlay. Wherever possible, it should be the aim to group the machinery and tools in such a way as to adopt three sizes of motor, and let us say, for example, 30 h.p., 15 h.p., and 5 h.p. In this way a spare armature for each type of motor will probably be found to be sufficient, and thus the capital expenditure on spares will be considerably reduced. It is quite true that a complication ensues in many cases from the variety of speeds at which tools have to be driven, but the author does not think that this is as bad as is made out, and in special cases, rather than instal a fourth size of motor, he would be inclined to modify the speed through gearing of some kind, even at the risk of some loss in efficiency. Then, the starting switches, the switchboard panels, and instruments could be made, say, of two sizes to suit the three classes of motor, and thus there will be some system instead of the too frequent and too great variety of instruments one sees installed. In a system carefully laid out, the cables can also probably be arranged to be covered by two sections. The arc lamps should be, if possible, of the same pattern, and the resistance or choking coils in connection with them should be of precisely the same pattern. Thus a very simple and easily understood system will be adopted with a resultant minimum first cost. If continuous-current dynamos be installed, the adoption of the three sizes suggested can also be probably arranged, and the same size of carbon brush (though a different number of each, of course) can be utilised, and thus only one size and style of carbon be kept in stock.

All electrical users having a number of motors will find it convenient to have a small portable blower as an auxiliary, mounted on a trolley, and by means of which the motors can be thoroughly blown out from time to time. It is advisable, of course, to have a totally enclosed motor, although rather more expensive in first cost for the same temperature limit. Yet even in this case it is advisable occasionally to have them thoroughly blown out and freed from dust. One of the greatest difficulties which manufacturers have is to ascertain the size of motor to attach to certain machines. In any case, with direct-current installations, it is always advisable to have the motors compound wound, and in cases of intermittent work, such as with punching and shearing machines, as an extreme example, it is necessary to supplement the motor by a heavy flywheel. These are points, however, upon which it is advisable to get expert advice, and to enter into a discussion of the sizes of motors for various industries would require a paper in itself.

The author is confident that transmission in the future in workshops and other factories will be almost entirely by electrical means, and one important point he would ask users to remember is the quicker rate of doing work which frequently results from the adoption of electricity. He would ask manufacturers to look at the cost of their power squarely. There are too many instances of such figures as ½d. per horse-power hour or less being given, which, when analysed, are soon proved to contain merely the cost of fuel and stores—not the whole of the wages, and only a vague idea of the repairs, with no provision for depreciation of plant, rating, interest on capital outlay, or general superintendence. He knows in many works it is difficult to arrive at a true assessment of some of these figures. That we have entered an era of the almost universal adoption of electricity he is quite certain. At the same time, manufacturers should not hastily adopt the new method, but should take time in laying out their works to the most economical advantage.

The author hopes this paper will be instrumental in making clear the *pros* and *cons.* for each particular user, and be of some assistance to non-electrical engineers who are contemplating the adoption of electricity. He has not entered upon the important question of the supply to collieries, which, under the admirable rules issued by the special commission appointed by the Home Office, will render the use of electricity in mines thoroughly safe, but it does appear as if a very considerable economy could be gained especially in these cases through the adoption

Digitized by Google

of electrical transmission. Several important collieries are now installing plant, and in a short time we shall have reliable data upon which to work. Manufacturers are to be congratulated upon the manner in which they have so readily adopted this agent on the North-East Coast, and electricity will, undoubtedly, play an important part in the economics of the district. The recent regulations of the Home Office are appended to the paper, and will be useful to members for reference. The author also recommends the study of the report by the Commission on the Use of Electricity in Mines recently issued. The author is indebted to the Home Office and to H.M. Electrical Inspector of Factories for permission to use these references.

## ADMINISTRATIVE COUNTY OF LONDON AND DISTRICT ELECTRIC POWER BILL.

(*Continued from page 446.*)

On Thursday, March 30, Colonel CROMPTON, R.E, continued his evidence, and stated that the promoters had not made sufficient allowance for depreciation and antiquation of plant. He did not think the promoters would get the results they expected from Newcastle slack. He had had experience of such coal, and found that it deteriorated from conveyance and after storage. The electricity supplied in Kensington and Knightsbridge was procured either from the company's stations or in bulk from the works in Wood-lane. Such works were ample for present demands, and could be extended to meet any expected increase. No economy would be secured by taking electricity in bulk from a new company.

Mr. HIGHFIELD, chief engineer to the Metropolitan Electric Supply Company, gave evidence as to the reduction in cost due to an increase in power-factor of the load, and with his evidence the opposition of the companies to the Bill closed.

Sir R. LITTLER, K C., stated the case for the Corporation of London. Two electric lighting companies had powers to open the streets, and the Corporation strongly objected to a third company having similar powers. Already the streets were crowded with pipes and cables for various purposes, and there was absolutely no room for more. The offer to go round and avoid main thoroughfares was of little avail, for there were no streets in the City that were not crowded during business hours. In the second place, as the purchasing authority the Corporation did not like Clause 69 in the Bill, which would give the promoters power to purchase an existing undertaking without the consent of the local authority. If the promoters were successful in inducing an existing company to sell their undertaking, there would be nothing to prevent the Administrative Company from discarding the existing generating station from which the local supply of electricity was drawn. Then when the time came for the Corporation to exercise their right to purchase, all they would become possessed of would be the mains within their area, and the electricity would have to be taken from the new company. The Corporation wished to remain in the position they now occupied, with power to acquire the generating station should circumstances require it. The City had nothing to gain from the Bill; a cheap supply was secured by existing competition. Let the City be left alone and he had nothing more to say, or he would be content with a provision that the new company should not come in without the consent of the Corporation.

Lord R. CECIL, K.C., called evidence in support of the petitions of 15 metropolitan local authorities, including those of Battersea, Bermondsey, Fulham, Hammersmith, Hampstead, Poplar, St. Marylebone, St. Pancras, Shoreditch, Stoke Newington, Woolwich, Camberwell, Deptford, Lewisham, and Isleworth.

Mr. PHILLIP DAWSON, of the firm of Messrs. Kincaid, Waller, Manville, and Dawson, submitted a number of tables compiled by himself giving particulars of the condition and capacity of the existing generating stations in the various districts. From these he showed how the costs of production decreased with the increase both of the load factor and the output. The average load factor for these stations was about 12 per cent. He did not believe that the promoters would get a 35 per cent. load factor, as neither the tramways nor railways were likely to take a supply from them. He considered that the railway companies could generate as cheaply as the promoters and save the cost of distribution. If the local authorities got a 35 per cent. load factor, they could supply as cheaply as the promoters. Under cross-examination, Mr. Dawson admitted that the capital cost of many of the stations in his table was high, and that this would affect the cost of the supply.

Mr. C. H. WORDINGHAM gave his opinion, after examination of the generating stations of the borough councils, that they were well equipped, had ample means for extension, and were, in fact, actually doing what the promoters proposed to do in the way of cheap supply of power. The advantages claimed from the placing of the proposed generating stations on the riverside were already realised in four of the stations he had inspected. The other advantages claimed from the use of large generating units and the supply of large users could be also secured by the present undertakers. He apprehended trouble from the ring mains, where breakdowns would be extremely serious. He had had experience of the damage done by short-circuits on mains carrying large power, and did not think automatic devices would satisfactorily guard against such damage.

On Friday, March 31, Mr. C. H. Wordingham, cross-examined, said that steam-turbines, like other machinery, were liable to be superseded, but local authorities should take the risk of that and allow for depreciation. Within certain limits the cost of production decreased with the increase of the size of turbines. He would not admit that mains were less liable to depreciation than plant. He had had to take up practically the whole of a large system of rubber cables laid in pipes after five years. He was averse to very large generating stations under the conditions prevailing in London. In reply to questions from the committee, the witness said the crowded state of the ground under the streets presented great difficulties, but not impossibilities. The danger which might result from a fault in the "ring" main he illustrated by an account of a serious explosion that occurred in Manchester two years ago. There was a small fault in the main—a far less powerful main than the proposed "ring"—an inflammable gas was generated from the covering of the cables, and this exploded and caused much destruction of property.

Mr. G. BELL, electrical engineer to the Hammersmith Council, submitted extracts from the accounts to show that the Council carried on their electrical undertaking at a profit and met the local demand for power at 1·07d. per unit. They had expectation of increased demands for traction purposes. The power load at Hammersmith took 31 per cent. of their total output.

Mr. S. BAYNES, electrical engineer for St. Pancras, gave similar evidence as affecting that borough.

Mr. P. V. MACMAHON, electrical engineer to the City and South London Railway, stated that the controllers of that line would not take electricity from the proposed company or from any other, the possession of a generating station of their own being the heart of their system.

Mr. FREEMAN, addressing the committee on behalf of the borough councils, argued that if the Bill were passed his clients would be prevented from supplying electricity for power, a source of profit in view of which they had constructed works at great expense. If they had been guilty of neglect in meeting demands for electricity, if they charged unreasonable prices, or if their supply were bad, he could understand acceptance of the new scheme. But even the promoters made no such allegations against them, and there was absolutely no reason why they should be penalised, as they would be if the Bill became law. No one could deny that there was very strong financial support behind the Bill. That financial strength might be used to ruin competitors by selling electricity below cost price, after which consumers would be at the mercy of the successful undertaking.

The case for the city of Westminster was then heard. The chief evidence given by the town clerk and the city engineer dealt with the purchase clause, and with the nuisance caused by the opening up of the streets by another company.

Digitized by Google

Mr. COWARD, representing the London County Council, said that body offered the most strenuous opposition to the Bill. The Council had lent more than £4,500,000 to local authorities in the Metropolis for establishing electrical undertakings, but the security for repayment of the money would be endangered if the scheme before the committee were sanctioned. Moreover, the County Council itself desired one of the powers sought by the promoters—that of buying out existing electrical undertakings.

On Monday, April 3, a statement was submitted by counsel for the promoters, showing in tabular form the Power Acts now in existence and the extent to which companies competed with local authorities in different parts of the country. Upon this a discussion took place on the circumstances and conditions in which areas of urban districts were included in or excluded from the powers conferred upon promoting companies. In most cases local areas were excluded after petitions from borough councils, but there were precedents in either direction, exclusion and inclusion. Where the consent of a local authority was required, such consent did not extend to electricity supplied for power purposes at a point outside the borough to railway, tramway, dock, and canal companies.

Mr. W. TAPPER, electrical engineer to the Stepney Borough Council, said that last year for private lighting the average price had been 2·75d. per unit, for public lighting the cost had been 1·56d., and the charge for power purposes 1·20d. The Council required further land for a new generating station, but he was not prepared to say that it would be more advantageous to take a supply in bulk from the proposed company than to incur the additional capital expenditure. The Council did not supply the docks within their borough, but informal negotiations had been opened in reference to a supply to the London Docks Company. He was sure that the Council would be able to continue to supply electricity for power purposes at the flat rate of 1d. per unit. The new generating station would cost about £260 000.

Mr. W. BULLOCK, electrical engineer to West Ham, explained the condition of the undertaking in that borough. This year it was estimated that three million units, or 50 per cent. of the total output, would be sold for power purposes. He believed they could supply power consumers at less than 1d. per unit. They had the option to buy in bulk from the Charing Cross and City Company upon agreed terms, but did not at present contemplate taking such a supply.

On Tuesday and Wednesday, April 4 and 5, the individual cases of other local authorities were heard in opposition to the promoters' scheme. Thus, the Councils of East Ham, Hackney, Southwark, Ilford, Gravesend, Dartford, Wimbledon, Bexley, Barking, Islington, and Croydon were all represented and offered evidence. This usually took the form of a review of the progress of the municipal undertaking and a statement as to the charges made for power supply. There was thus a considerable amount of similar evidence offered, which, by its weight, may convince the committee. The arguments of the many counsel employed were to the effect that each authority was doing what the promoters wished to have powers to do, and that if the Bill were passed the competition would be an unfair one. They urged that the company would secure all the large power and light consumers, and in this way reduce the value of the local undertaking. The decreased load would then make the local supply unremunerative, which might result in the undertaking being bought up by the promoters. Then it was argued that the prices would be raised.

Mr. PHILLIP DAWSON, recalled, gave the result of a calculation he had made of the cost of laying two mains from the contemplated generating station to Gravesend and Dartford. The capital cost of two mains to Gravesend would be £38 000, and the cost of a transforming station would be £4,000 more. The 20 per cent. on the outlay, which had to be guaranteed by the local authority, would work out at £8,436 as against £4,759, the total cost of production last year with their own generating station. The Dartford mains would not cost so much, but here, again, the 20 per cent. charge was equal to more than the present cost of production.

## THE USE OF ELECTRICAL ENERGY IN MINES AND COLLIERIES.

The excellent paper read by Mr. W. B. Mountain, M.I.E.E, on the 28th ult. before the Manchester Section of the Institution, is one which cannot well be condensed, owing to the extremely wide range covered. The paper was illustrated by diagrams and lantern slides numbering over 70, which would need to be reproduced if the paper were to be given in full. We propose, therefore, to content ourselves with a very brief *résumé* of the paper and of the discussion. In the first place, Mr. Mountain devoted himself to what had been done in the adoption of electrical driving in mines and collieries, rather than to what was to be in the future. He dealt with the parliamentary enquiry on the subject, and also with the rules recently issued as to the same, which allow of the introduction of high voltage into a considerable portion of a colliery. In discussing the advantages of the different systems, three-phase and direct-current, Mr. Mountain concluded that a combination of the two was likely to be of the most advantage. For this purpose double-current generators could be used, or, for larger plant, three-phase currents might be generated, and a certain proportion of the output converted into low-tension direct current. In dealing with the various portions of colliery and mining equipments, great stress was laid on every part being of the best possible type, in view of past experience in mining work. The latter portion of the paper, which was profusely illustrated, showed those present at the meeting what had been done in the various departments of mining as regards electrical driving. Thus, electrical winding gear, electrical pumps of various types, and electrical ventilation were all treated on more or less fully. On electric coal-cutting a great deal of information was given, and some excellent results obtained with the "Pickquick" electric coal-cutter were quoted. Thus, one of these machines, manufactured by Messrs. Mavor and Coulson, actually cut 25,535 tons of coal in 1904. It worked regularly for five nights per week, and the repairs came out under £1 for the year. On the subject of rock and coal drilling, the electric drill is in strong competition with the compressed-air drill. While the costs with the electric drills are considerably lower than with those driven with compressed air, the latter is still largely employed, owing partly to the objection to taking electricity up to the working face. In such cases, considerable saving is secured if the compressed-air drills at the face are supplied from small electrically-driven air-compressors near at hand. Lastly, Mr. Mountain dealt with electric traction, for which he considered there was a still a large field in the mines in this country. The lists given at the end of the paper are specially interesting, as showing the advantages of the electrical working. Actual figures are given in a number of cases of the annual saving which has been secured. Other schedules give the essential details of some of the most prominent British installations in mines, while the third gives the same information for a number of mines on the Continent. The figures as to electric winding gears and electric coal-cutters complete a paper which will be highly appreciated by all colliery engineers.

The following is a *résumé* of the discussion on the above paper:

Mr. C. D. TAITE, the chairman, welcomed the paper as dealing with a subject without which no electrical engineering society's syllabus was now complete.

Mr. A. H. GIBBINGS referred to the difficulty of finding a list of collieries with electrical installations. Nothing appeared to be published of a complete nature. He hoped Mr. Mountain would give details of power required to work the apparatus illustrated. He pointed out some obvious misprints in the proofs distributed. In his opinion the recent papers read before other branches of the Institution, and before the Civils, were not so complete as they might have been.

Mr. G. PREECE thought that a number of mining engineers still required educating up to the advantages of electrical working, and that harm had been done to its good name by some badly executed jobs, for which defective supervision was chiefly to blame. Trouble also arose when unskilled men were employed to run the electrical plant. As regards safety: he agreed with the views recently expressed that high tension was really safer than low tension in practice, as the miners were

Digitized by Google

more respectful in their dealings with cables and apparatus working at high potentials; and in the half-naked and perspiring state of the miners a low-tension shock was just as likely to damage as high-tension. There was not much of a demand for rubber-insulated cables as mains now, as bitumen and paper lead-covered were becoming popular on account of their cheapness. Bitumen insulated cables were, in his opinion, the more satisfactory of the two classes for low-tension mains, on account of lightness and waterproof qualities without lead sheathing; also, the ends were more simply insulated. They were not so suitable for high tension, however, as in the multiple-conductor cables used on alternating currents there was a chance of the conductor decentralising through the bitumen; although a layer of paper next to the conductor would minimise that, such as in the paper leadless cables now on the market. For use with coal-cutters and motor connections rubber was still the best on account of its flexibility, but such leads should be suitably protected against the severe usage they had to experience, and he believed that leather braiding, although dearer in first cost, would prove the best form of protection. Some mining engineers preferred their cables to hang free from the surface to the pit bottom, and such an arrangement was in successful use. He preferred cleats for deep shafts, however, but care should be taken that no projections were left for dust, etc., to lodge, or for falling bodies to damage. In the workings cables were best suspended from the props or walls by leather clips, preferably one cable on each side of the road on continuous-current circuits. Although the Board of Trade rules mention wire armour for protection, he recommended a fibrous braiding as less likely to damage the cable itself when heavy weights were dropped on it, and he pointed out the danger to be anticipated from a wire armour rendered alive by being forced through the insulation on to the conductor in a pit where earthing was impossible and where men came in contact with the armour.

Mr. WILLIS accentuated the huge strains that colliery motors were subjected to, so that in some cases keyways were stripped and shafts had broken off close to the motor. With hauling gear, if a truck full of coal went off the line the motor was expected to drag it back on the rails! For such work an elastic gear was required, such as ropes or belts, and direct-current machines stood up to the work better than polyphase.

Mr. A. G. COOPER instanced some early electric experiences in mining work, when enclosed motors were first used, and liquid starters were tried.

Mr. J. D. BAILIE mentioned that the bad water to be met with was more injurious to ram pumps than to the centrifugal type, and stated that a Mather and Platt centrifugal tested to 63 per cent. efficiency. He instanced a total cost of ·54d. per unit at a colliery where the load factor was, singularly enough, 54 per cent. He related the amusing history of an electrical coal-cutting machine, that spent more time at the photographer's and repair shop than in doing work during the period of its useful life.

Mr. A. C. CORMACK recommended continuous current for general use as more adaptable to pumping where sumps were so shallow, etc., as to make a too variable load for three-phase machines.

Mr. MOUNTAIN, in reply, agreed that it was difficult to get details of electrical work in mines, but understood that fuller data were being made now. As regards burying cables under the roads being a more permanent job, he mentioned the probability of their eventual non-accessibility owing to the gradual covering up by *débris*; and in reference to some speakers' anxiety as to the trouble of getting bulky machines down to their positions underground, he assured them that mining machinery was made in sections specially suitable for the job of transport and erection in mines.

## BOSTON ELECTRIC LIGHTING SCHEME.

### Local Government Board Decision.

**The Corporation of Boston recently applied to the Local Government Board for a loan of £20,000 for electric lighting purposes. The usual enquiry was held, but the evidence was not such as to convince the Board of the soundness of the proposed scheme. The result is that the whole matter is referred back to the Corporation. In view of the closeness with which the details of all such schemes are now examined when loans are applied for, the following letters are of general interest:**

BOSTON ELECTRIC LIGHTING ORDER.

Local Government Board, Whitehall, S.W., March 14, 1905.

Sir,—I am directed by the Local Government Board to state that they have had under consideration the report made by their inspector, Mr. Hooper, after the enquiry held by him with reference to the application of the Town Council of Boston for sanction to borrow £20,000 for purposes of electric lighting.

The Board are not satisfied upon the information before them that the establishment of an electric lighting installation in accordance with the scheme as at present designed would be likely to be successful from the financial point of view, and they are advised that, apart from this question, there are several matters in connection with the proposed scheme which require attention.

The Board think, therefore, that the Town Council would be well advised to reconsider the whole matter, with particular reference to the following points:

1. The substitution of electric lighting for the present system of gas lighting in many of the streets would admittedly entail a considerable increase in the public expenditure on lighting; but it was not satisfactorily shown that there would be any material improvement in the lighting of these streets, and looking to the arrangement of the arc lights shown on the block plan, it is even possible that the illuminating effect of the electric light might be inferior to that of the present method of lighting by gas.
2. The Board understand that there is already a modern and efficient plant in operation for lighting the docks by means of electricity, and as at present advised they are doubtful whether the proposal of the Town Council to supersede this plant and to light the docks from the general installation proposed would be economical. If this proposal is adhered to, the Town Council should obtain comparative figures of the cost of lighting the docks from the present plant and from the proposed installation (taking into account the capital expenditure involved by the present proposal), and submit them to the Board with the revised scheme.
3. The Board are advised that the laying of distributing mains along several of the routes chosen would be likely to prove unremunerative, and, in their opinion, the whole question of the routes for the mains should be carefully reconsidered with the view of omitting from any scheme those streets in which it is clear that there would be no adequate return on the expenditure. In this connection the Board direct me to enclose a copy of a letter which they have received from the Board of Trade.
4. The Board are also advised that the arrangement of the generating station is capable of considerable improvement, especially with regard to possible future extensions. They direct me further to point out that the evidence given at the enquiry indicated that the spare unit would have to be used daily in order to carry the estimated peak load.

Looking to the large amount of expenditure proposed, and having regard to the fact that the ultimate success of schemes of electric lighting so largely depends upon the original design of the works and upon the primary arrangements and the details of the scheme, the Board would recommend the Town Council to consult an electrical engineer of high qualifications and experience before finally deciding on a revised scheme.

The plans relating to the present scheme are returned herewith.—I am, sir, your obedient servant,

NOEL T. KERSHAW, Assistant Secretary.

The Town Clerk, Boston.

Copy of letter from the Board of Trade referred to in a letter from the Local Government Board:

Board of Trade (Harbour Department),
7, Whitehall-gardens, S.W., Feb. 14, 1905.

BOSTON ELECTRIC LIGHTING ORDER, 1900.

Sir,—I am directed by the Board of Trade to acknowledge the receipt of Mr. Kershaw's letter of the 9th inst., on the subject of the above-mentioned order, and, in reply, I am to point out that the order imposes upon the Corporation of Boston an obligation to lay mains in all the streets specified in the third schedule to the order.

Should, however, the Corporation establish an electricity scheme which does not include the laying of mains in some of the scheduled streets, the Board of Trade would not be likely themselves to raise any question in the matter unless representations were made to them, but if representations were made the Board would have to consider them.—I am, sir, your obedient servant,

T. H. W. PELHAM.

The Secretary, Local Government Board.

**These letters have been considered both by the Lighting Committee and the full Council of the Boston Corporation, but so far no definite decision has been come to. Such a result is discouraging to those responsible for the scheme, but it is to the interest of all in Boston that the electric supply undertaking should be started on economic lines, and with due regard to probable extensions. With gas at 4s. 4d. per 1,000 there must be a good opening for electric lighting. With the aid of a good consulting engineer the Corporation should promptly reconsider their plans. It is obviously better to revise the scheme now than to find after completion that the undertaking is too large and a burden on the town.**

## TRADE NOTICES AND NOVELTIES

### The Meridian Lamp.

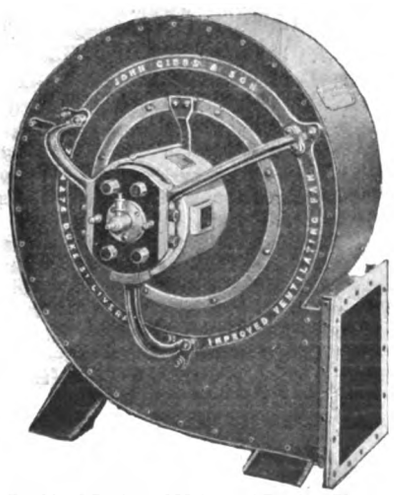
The lamp which we illustrate herewith is made by the British Thomson-Houston Company, of Rugby, and has been given the above name. Its object is to secure a good distribution of light on a horizontal surface when the lamp is arranged vertically. In order that this may be accurately done, to get the best effect from the energy expended the following points have been carefully attended to. In the first place, the shape of the filament and its position in the bulb is special, and also the exact shape of the reflector is the result of careful study. This special prismatic glass shade is rigidly fixed to the lampholder, so that the Meridian lamp can be burned in any position, and the same distribution of light obtained as when arranged vertically.

B.T.H. Meridian Lamp.

Hitherto these lamps have only been made for use on 100-125-volt circuits, but we understand that the British Thomson-Company have, after a series of exhaustive experiments, developed a 120-watt Meridian lamp for burning in multiple on circuits of from 200 to 250 volts, and are prepared to fill customers' orders immediately from stock. The attractive appearance and neat design of the Meridian lamp makes it particularly desirable for all kinds of interior decorative work where a downward distribution of light is required.

### Electric Fans.

It is well known that Messrs. John Gibbs and Son, Duke-street, Liverpool, have given a large amount of attention to the question of mechanical ventilation. We would refer here more particularly to the success which has rewarded their efforts afloat. Thus some of the finest and largest steamships in



Combined Dustproof Motor and Peerless Blower.

the world, including the Cunard R.M. ships "Campania," "Lucania," "Caronia," and still more recently the turbine steamer "Carmania," have been fitted with the firm's patent weatherproof ventilators. By means of the system adopted on these vessels the air in all the third-class passenger spaces is renewed each five minutes, the temperature being adjusted according to the atmospheric conditions prevailing. It speaks well for the practical success of the system that after thorough tests on the two first-mentioned ships it should have been adopted on the latest additions to the Cunard fleet.

However, Messrs. John Gibbs and Son by no means confine themselves to marine work. They have also, among other departures, specialised the design of plants for warming and ventilating workshops, mills, and factories, and for collecting dust from polishing shops, woodworking machinery, etc. The accompanying illustration shows one of their newest forms of combined patent dustproof motor and Peerless blower, a most convenient form of apparatus, which has given highly satisfactory proofs of efficiency on test. The makers are, therefore, able to recommend this fan with every confidence as giving the best possible results for the power expended.

### Wirt Brushes for Dynamos and Motors.

We had occasion as recently as October last to comment favourably on these brushes, but a good thing cannot be too well known, and a price-list just issued by Messrs. J. Defries and Sons, Limited, 146-147, Houndsditch, London, E.C., the sole licensees and makers, contains some further information to which we would call attention here. It is claimed that Wirt brushes give to machines designed for metal brushes the advantage in respect of sparkless commutation which has hitherto had to be sought in carbon brushes, without the increase of dimensions and waste of current which carbon brushes entail, and with a substantially increased life of commutator and brush. Each brush consists of a series of very thin laminæ

Wirt Brush-holder.

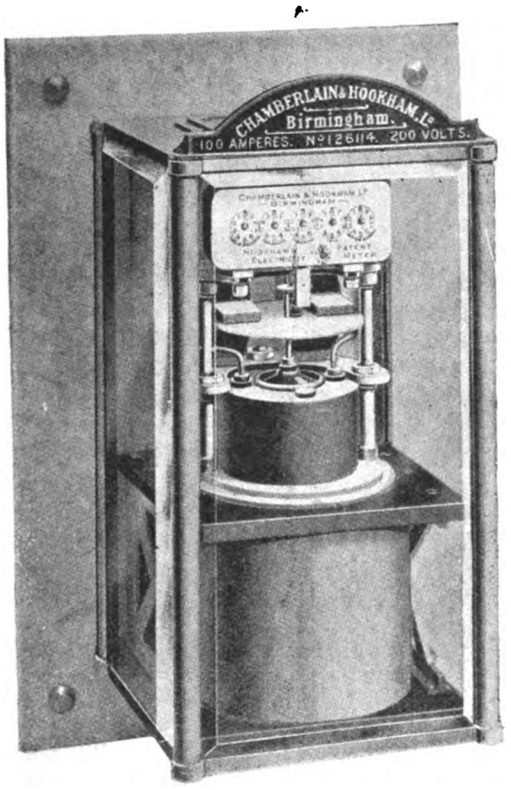
of metals of special compositions and degrees of resistance, held along most of their length between two spring cheeks, and fixed together solidly at the end which enters the holder. The laminæ by which the current is most readily conveyed are of copper, being sandwiched between a series of anti-friction metal laminæ of increasingly higher resistance, so that the brush cuts out and cuts in each armature coil through resistance, which tends to prevent sparking, without wasting current by a needlessly high resistance. The composition and sequence of the resistance metals vary with the type of machine for which the brush is intended. The operation is to some extent analogous to that of starting a motor through a resistance which is gradually cut out as the E.M.F. of the motor approaches that of the line. The individual elasticity of the laminæ causes it to make good contact on the commutator with very little bearing pressure, and it has repeatedly been found that a Wirt brush will, through its "cushion" touch, make perfect contact on a commutator so rough as to cause any other brush to fail. On alternating-current collector rings, where the question of sparkless working does not arise, this quality makes the Wirt brush convenient and profitable in wear. The large proportion of anti-friction metal in the Wirt brush causes its wear on the commutator to be almost imperceptible, the worst cutting of a commutator occurring through the friction of copper on copper. Wirt brushes can be fitted to any existing dynamo or motor designed for any form of metal brushes, but are usually unsuitable for machines originally fitted with carbon brushes. In "arc dynamos" they cannot suppress sparking to the same extent as in other machines, owing to the relatively high resistance of the armature and the high tension; what is obtained by their use on such machines is reduction of sparking, improved smoothness of running, increased life of brush, and less frequent need of attention. We understand that for plating and electrolytic purposes these brushes are working successfully up to 4,000 amperes, and are already in very extensive use. Several excellent testimonials are included in the list under review, also some illustrated notes on the care of Wirt brushes, which should be widely appreciated.

### Chamberlain and Hookham Meters.

The new catalogue of Messrs. Chamberlain and Hookham has just reached us, and contains descriptions of several new features in the electricity meters manufactured by this firm. The list of stations where these meters are employed gets longer with every issue of the catalogue, which speaks well not only for the meters, but also for the commercial organisation of the firm. Amongst the old friends in the catalogue we notice the battery meters for recording the charge and discharge of accumulators in central stations. Two meters are employed, one for the charging current and the other for the discharging. The current goes through the two meters in series, but only one meter can revolve when the current is going in a definite direction. When the current is reversed the other meter commences to record, the armature of the first being held by means of a rachet and pawl. These meters are now supplied handsomely mounted in brass cases for mounting direct on switchboards. The new feature in this list is the form of watt-hour meter which we illustrate herewith. It is a modification of the

Digitized by Google

ampere-hour type, in which the permanent magnets are replaced by an electromagnet energised by a shunt coil across the mains. These meters are for use in stations supplying tramways, or power circuits where a considerable variation of voltage may occur. Although the driving field is electromagnetic, permanent magnets are still retained for the brake. The following description brings out the new details in this meter. The armature is cylindrical and similar to those supplied in the 1902 type of meter, and carries on its spindle the aluminium brake disc. The mercury is contained in a chamber bored out of an ebonite block and having conducting strips embedded in it. The pole-piece of the electromagnet projects up inside the armature and carries the bottom pivot on which the armature runs. In order that the field of the electromagnet may respond perfectly and instantly to changes of pressure there is no external pole-piece to the outside of the armature, so that the magnetic circuit is completed through the air. The coil of the electromagnet (which is of fine wire) is below the mercury bath. It is wound upon a straight core which carries the one pole-piece at its upper extremity. In order to ensure entire absence of residual magnetic effects in this core a special method of construction has been adopted. Instead of being made of a solid bar, it is made up of a pile of iron washers with insulation between them. When magnetised, therefore, the entire iron circuit is made up of a number of very short magnets in proportion to their length. These magnets have a



Chamberlain and Hookham Meter.

great self-demagnetising tendency, which operates the moment the magnetising current is withdrawn or diminished. It will be seen from the above that the electromagnet field is made independent of residual magnetism in the iron circuit by introducing a considerable amount of air resistance into the same. In this way a magnetic field is produced which is strictly proportional to the current in the magnetising coil, and hence to the voltage across the mains. As the current only passes through the armature of the meter, a short-circuit does not affect the magnet. These meters are constructed to carry 50 amperes maximum, and if larger currents have to be measured they are passed through a shunt, the ends of which are connected to the meter terminals. These meters are usually mounted in polished cases with glass fronts and sides for placing on switchboards. The other details of the meter are worked out in accordance with Messrs. Chamberlain and Hookham's usual practice, and in this type, again, the weight of the armature is entirely borne by mercury, so that there is no tendency for the pivots to wear.

## Catalogues Received.

TRANSPORT CELLS.—We have received from Messrs. Siemens Bros. a number of recently issued publications, including a leaflet describing their patent transport cells, which combine the advantages of both wet and dry types of primary batteries. It is designed especially for motorcar ignition. Essentially it is a wet cell, and, consequently, the electrolyte can be renewed when required, but the mechanical construction is so arranged that there is no chance of the liquid escaping unless the cell has been severely damaged. Another advantage of the type is that they can be kept for any length of time in a dry condition. If desired, they can be emptied after use, rinsed out with warm water, and then laid aside for future use. All that is then required is to introduce a solution of a special salt, recommended by the makers, into the cell to put it again into working order. It can be worked, however, with ordinary salammoniac. The batteries are made in four different sizes, the voltage of the cell being 1·5. For use with motor bicycles three of the middle-size cells are recommended, which weigh in all 8¾lb. The other lists received from this firm give particulars of their open-type dynamos and motors, with standard dimensions of the same. We have also received a list which shows the leading dimensions of the S. K. cut-outs manufactured by Messrs. Siemens Bros.

"BROCHIPEL" ARC LAMPS.—Several new types of enclosed arc lamps are dealt with in the latest list issued by the Brockie-Pell Arc Lamp Company, Limited, 60, Worship-street, London, E.C. These types include the ordinary pattern for streets, factories, wharves, mills, yards, etc., the shop window pattern, the twin carbon pattern, and ornamental patterns.

D.C. MOTORS.—Messrs. Vickers, Sons, and Maxim, Limited, Sheffield, have sent us a copy of their D.C. catalogue, Section 1, which deals with direct-current protected and enclosed constant-speed motors for outputs ranging from 5 b.h.p. to 50 b.h.p.

SMALL MOTORS.—From the British Thomson-Houston Company, Limited, Rugby, we have an illustrated circular showing various special applications of their small-size motors.

HOLMES AND CO.'S LISTS.—Messrs. J. H. Holmes and Co., Newcastle-on-Tyne, have sent us a list of the electrical plants which they have supplied to engineering firms, shipyards, railways, and dockyards; also an interesting illustrated description of the Holmes-Chatworthy system of operating newspaper web rotary printing machines, which has already been extensively adopted.

WILLANS ENGINES.—The economy of the Willans engine is dealt with in an illustrated pamphlet recently issued by Messrs. Willans and Robinson, Limited, Rugby. Some excellent results are recorded.

CONDENSING PLANT.—We have received from the Mirrlees-Watson Company, Limited, Glasgow, a well-illustrated pamphlet describing the various types of condensing plant manufactured by them and the conditions for which each type is most suitable.

ARC LAMPS AND ACCESSORIES.—The Sun Electrical Company, Limited, 118-120, Charing Cross-road, London, W.C., have sent us an illustrated list of the arc lamps and accessories which they supply.

ELECTRICAL COMPANY'S LITERATURE.—From the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., we have two illustrated circulars, one of which deals with their projector Nernst lamp, and the other with high-voltage wall sockets and plugs; also three sheets illustrating respectively the generating station at the Grand Hornu Colliery, a large electric winding engine, and a group of three-phase motors supplied to the Western Australian Government.

SIMPLEX STEEL CONDUIT.—A useful little reference list, in a red cover, for the pocket has been issued by the Simplex Steel Conduit Company, Limited.

## PERSONAL.

CORRECTION.—We regret that in our last issue in referring to the appointment of a third engineer-in-charge at Bermondsey the name of A. B. Gundry was given as the successful candidate, instead of that of Mr. W. Panpred, of Manchester, who was actually appointed. There were over 90 applications for the post.

The Derby Electricity Committee recommend the appointment of Mr. J. Hebb as canvassing engineer, at a salary of 2bs. per week, together with a commission of ½d. per 8-c.p. lamp up to 10 000 lamps obtained by him in one year, and 1d. per lamp above 10,000 obtained by him in the same year.

The Liverpool City Council have increased the salary of Mr. C. R. Bellamy, the tramways manager, from £1,200 to £1,500 per annum.

## APPOINTMENTS VACANT.

**Tramways Inspector,** Birmingham Corporation. Salary about £4 per week. Applications by April 12. See advertisement in last issue.

**Assistant Lecturer in Engineering,** Swindon Education Committee. Salary, £150 per annum. Applications by April 29. See advertisement.

**Agents** for switchboards, transformers, instruments. See advertisement.

**Pupil,** L. H. King, Council Offices, Whitby, Yorkshire. See advertisement.

*Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday.* **Special Terms** *for a series can be arranged on application.*

**SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.**

### TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

| | 3 months. | 6 months. | 12 months. |
|---|---|---|---|
| United Kingdom | 3s. 3d. | — 6s. 6d. | — 13s. 0d. |
| Other Places | 5s. 6d. | — 10s. 6d. | — 21s. 0d. |

Post Free, Payable in Advance.)

*Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to* C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

*Bound Volumes of* "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, July to December, 1904, now ready.*

## TRAINING, EDUCATING, PIONEERING.

It is not customary to refer to the social functions resuscitated by the Dynamicables, yet the chairman, Mr. J. Fletcher Moulton, M.P., at the annual meeting on Wednesday, in responding to the toast of the society, made several references which ought always to be kept in mind. Referring to the earlier history of the society, it was suggested that in those days everybody who cared to dub himself an electrical engineer was acknowledged as such; in fact, the world took him at his own estimation. Usually the aspirant to the profession was full of imagination, one of the most vivid of the imaginings being that the discovery or the mixture of a new coloured paint was enough to ensure him a valid patent for a new dynamo. Brains were somewhat at a discount, but the lapse of a quarter of a century or so has largely changed these views. Nowadays the inventor, the improver, is a man who must have undergone a long, strict, and thorough training—one who knows the whole ins and outs of his subject. Thus the brain energy of the professional nation is awake, eager to compete in the race with all and every, and, according to the witty and learned chairman, our present position is one that does not fear comparison with the position of other enterprising nations, and is one which, if continued with energy and ability, will not fail to put us again into the supreme position amongst engineering nations we so long enjoyed. It is not, however, to the marked advance in knowledge and ability that we desire to direct attention, but to the strong indictment of the scurvy method of treatment to which British pioneer workers and investors have been subjected, which treatment lost us the race and makes it an arduous task to regain the lead. Pioneer work takes great risks and determines many problems, and surely the equitable result would be for those who take the risks and solve the problems to reap a commensurate monetary reward. The history of this nation, however, is very largely a history of ruined pioneers, a history of shattered hopes, and a history of the great success of those who simply took advantage of the work of others, reaping where they had not sown, and gathering riches at someone else's expense. There is not a single direction among the industries of this country wherein glaring instances of these things cannot be found. It matters not whether we look upon the literary, scientific, or mechanical work, the same thing holds good. The successful issue of a paper of snippets is followed by others as nearly resembling it as can be. One political paper has a column devoted to fashions, another and another follows suit—the pioneer gets no return for his original conception. In applied electricity we have very glaring cases of pioneer work not being adequately remunerated, nor adequately considered. At the present time pioneer lighting and power installations are threatened with extinction, because their success has shown how to provide something simpler and cheaper. As Colonel Holden says in the *Times* of April 5: "As regards the capital outlay involved and the interest thereon, and the depreciation of plant, it is pretty obvious that those who are the latest comers are, or should be, able to profit by the experience of others, and should be able therefore to select not only the best but the most economical type of generating machinery for their stations, and they ought, moreover, to select the most suitable sites and sizes for their stations. It is, therefore, only reasonable to suppose that in these respects the advantage should be on their side when compared with existing undertakings as regards cost of production and lower depreciation." These remarks only corroborate those of Mr. Moulton. In each case it is shown that the pioneer suffers

Digitized by Google

by competition with those who have learned from the experience of their predecessors. Where exactly the line can be drawn to satisfy the pioneer, and at the same time to satisfy the conditions of progress, it is difficult to say, but in some cases the correct method of treatment is clearly indicated. Take the case of an installation of light, power, or telephony in town or district called A. This installation is carried out under certain estimates of success. If those estimates have influenced the capital to take the risks, and those estimates are obtained in practice, it seems to us that capital has nothing to grumble at. If, on the other hand, those estimates are detrimental to the public—that is, make something more costly than it was before—or time shows those estimates to have been utterly untrustworthy, fanciful, and unwarranted, interference may be justified. Further, if the estimates were warranted by the facts of the case, and before the time had elapsed when full success could be obtained improvements were indicated, it does not absolutely follow that the pioneer capital should be jeopardised in order to let someone compete against it with the very improvements it has brought about. Here is the matter in another way. A has a house lighted by candles or oil. A seller, B, offers to *enter into an agreement* with him for twenty-one or forty-two years to light the house electrically—better and cheaper than it is lighted at the time of the agreement. A and B make such agreement. Ten years after C comes along and promises to undersell B because he can produce cheaper than B by means of experience gained from B. Is it altogether equitable that A or C should be allowed by some new legal dispensation to break the agreement? Yea, verily, pioneers have a hard time.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### CONTINUOUS-CURRENT TRANSFORMER.

SIR,—I should like to correct a statement which "Research" makes in his answer to Question No. 767, which is about a breakdown between the high-tension and low-tension windings on a continuous-current transformer. He says that after the fuses on the faulty machine have blown, etc, the battery will commence to discharge through the boosters unless they are fitted with automatic switches to connect the battery straight on to the 'bus bars and to cut out the boosters. I now quote from his answer:

"If there is no device of this kind, the current will be flowing in the reverse direction through the battery booster armature, and as the shunt winding will remain the same, the booster will tend to run as motor in reverse direction, whilst the balancers are striving to run in the ordinary direction, with bad results for the battery booster."

I quite agree with him that the armature current will be in the opposite direction, and that the shunt field will be in the same direction as previously, but obviously it is incorrect to say that the booster armature will tend to run in the contrary direction to what it was previously running in.

If "Research" applies the right-hand rule to the case when running as a generator, and the left-hand rule to that when running as a motor, he will see the fallacy of his statement.—Yours, etc., ERNEST R. ALEXANDER.

### THE LONDON COUNTY COUNCIL TRAMWAYS BILL.

SIR,—My attention has been called to a circular letter which has been issued by Messrs. Thomas Tilling, Limited, omnibus proprietors, with the intention of exciting opposition to the proposal contained in the Council's Tramways Bill of the present session for the construction of tramways over Westminster Bridge, along the Victoria-embankment and over Blackfriars Bridge, to connect the existing tramway termini in Westminster Bridge-road and Blackfriars-road. The letter contains the following paragraph:

"You can safely affirm that these tramways are not self-paying, and that a better service can be given to the travelling public with motor omnibuses by private enterprise, and without being a burden to the rates."

This statement is to my mind likely to so seriously mislead the House of Commons in its consideration of the Council's proposals, that I desire to trespass shortly upon your space to indicate what are the facts concerning the working of the Council's tramways.

The Council's tramways have from the first year that it acquired control of any lines in London been entirely self-supporting, and they will continue to be so. Even during the years when the bulk of the tramways south of the Thames were being reconstructed for electrical traction, entirely disorganising the ordinary traffic (some of the lines being closed altogether), the tramways account has never been a charge to the extent of a single penny upon the rates. On the contrary, the tramways have already during the past eight years paid from surplus revenue in reduction of rates, after the provision of interest and sinking fund charges, a sum of over £293,000, divided between the northern and southern systems.

The following details as to the application of the moneys received from the tramways account during the past eight years, in respect of the Council's systems north and south of the Thames, indicate the absolute inaccuracy of Messrs. Tilling's statement:

| | |
|---|---|
| Applied in reduction of rates, over | £293,000 |
| Amount paid for sinking fund charges in reduction of debt during the same period (northern system which has been in Council's hands for eight years, £117,044; southern system, which has been in Council's hands six years, £210,195; and general, £6,997) | 335,236 |
| Amount paid for interest on capital | 414,000 |
| Amount set aside as a reconstruction renewals reserve fund for the southern system | 66,000 |
| Amount paid in rates and taxes in respect of the southern system during the past six years | 90,000 |
| Amount paid in reduction of debt from proceeds of sale of horses, rolling-stock, surplus property, etc. | 126,220 |

During the four years from 1899 to 1903, the 48 miles of tramways north of the river, which are leased by the Council, earned as profit, after paying interest and sinking fund charges, £153,700; while the 24 miles on the south side of the Thames, worked by the Council itself during the same period, provided, after paying corresponding charges, the sum of £72,900.

The following facts are of importance in any institution of a comparison between the results from the system north of the Thames, leased to a company, and the lines south of the river worked by the Council itself. These illustrate the advantages that have been secured to the travelling public and the amelioration of the conditions of labour of the tramways employés obtained from the Council's immediate control:

1. 200,000,000 passengers were carried at ½d. fares, as compared with 1d., the minimum fare on the north. This represents a very considerable money value to the travelling public on the south side of the river.

2. Workmen's cars, running up to 8 a.m., have been instituted with a fare of 1d. for any distance for a single journey on the existing lines, and 2d. for a return journey, which means a very valuable boon to workers using the southern lines. In addition, all-night cars services have been established.

3. The Council has conceded to its employés a six days' week and a 10 hours' day, which with certain other improvements in the conditions of labour, represent an expenditure beyond that involved under this head when the tramways were acquired of over £30,000 a year. This ensured the granting of conditions of labour which were considered necessary to secure efficient service.

During the period of reconstruction there was a deficiency in the southern tramways accounts of £2,250 in 1902-3, and of £8,284 in 1903-4. This result was brought about by the Council paying interest and sinking fund charges of £12,300 on expenditure incurred for reconstruction before a single electric car was run on the lines creating

Digitized by Google

those charges. Moreover, during the first-named year a sum of £11,000 was set aside out of revenue for the renewals fund for the horse lines which were, at the time, entirely disappearing. The result of this was to give to the Council as an asset in the way of a renewals reserve fund a sum of £30,750 at the commencement of electrical working, before any wear and tear had begun, and the "account deficiency" is thus amply covered by assets more than corresponding thereto.

The facts, therefore, only serve to illustrate the soundness of the Council's tramways finance policy. In regarding this aspect of the matter I should like to point out that, contrary to company practice, the capital expenditure, a term by no means elastically interpreted by the Council, is being steadily paid off, and the tramways are being put in a better financial position every year, a constantly increasing sum being available by way of surplus receipts. In other words, a leasehold property is being rapidly converted into a freehold one, while a company undertaking remains a perpetual leasehold. The importance of this point cannot be over-estimated.

As the period of reconstruction passes away the "account deficiencies" will entirely disappear, and it is important to note that the accounts for the present year show a very substantial surplus, after the payment of the very heavy capital charges upon the lines that have been reconstructed. To the impartial expert it would appear that the Council has surmounted the difficulties of traffic maintenance and organisation during the trying period that comes in the history of every horse-propelled tramways undertaking when improved methods of traction have to be applied to the lines, with remarkable success.

In criticising Messrs. Tilling's letter in the light of the actual facts, I can only think that they are not prepared to rely upon the efficiency of the motor omnibus service as a means of locomotion in fair and open competition with the tramways service. I cannot otherwise account for the methods adopted by them in their endeavour to defeat the Council's efforts to improve the locomotion system of London in the best interests of the travelling public.—

Yours, etc. J ALLEN BAKER,
Chairman of the Highways Committee.

County Hall, Spring-gardens, S.W., March 31, 1905.

## IRON AND STEEL INSTITUTE.

The annual meeting of this body will be held at the Institution of Civil Engineers on Thursday and Friday, May 11 and 12, commencing each day at 10 30 a m. The following is the programme of the proceedings:

THURSDAY, MAY 11.

The retiring president, Andrew Carnegie, Esq., LL.D., will induct into the chair the president-elect, R. A. Hadfield, Esq. The Bessemer gold medal for 1905 will be presented to Prof. J. O. Arnold (Sheffield) The awards of the Andrew Carnegie gold medal and research scholarships for 1905 will be announced. The president will deliver his inaugural address. A selection of papers will be read and discussed.

FRIDAY, MAY 12.

A selection of papers will be read and discussed.

In the evening the annual dinner will be held in the Grand Hall of the Hotel Cecil.

The following is a list of papers that are expected to be submitted:

1. "On Experiments on the Fusibility of Blast-Furnace Slags." By O. Boudouard, D.Sc., Carnegie Research Medallist, 1903 (Paris).

2. "On Recent Developments of the Bertrand-Thiel Process. By J. H. Darby (Brymbo) and G. Hatton (Brierley Hill).

3. "On the Application of Dry-Air Blast to the Manufacture of Iron." By James Gayley (New York). Supplement to paper read on Oct. 26, 1904.

4. "On the Effect Produced by Liquid Air Temperature on the Mechanical and Other Properties of Iron." By R. A. Hadfield, president.

5 "On the Cleaning of Blast-Furnace Gas." By Axel Sahlin (London).

6 "On the Failure of an Iron Plate through Fatigue" By S. A. Houghton (London).

7. "On the Continuous Steelmaking Process in Fixed Open-Hearth Furnaces." By S. Surzycki (Czenstochowa, Poland).

8. "On Accidents due to the Asphyxiation of Blast-Furnace Workmen." By B. H. Thwaite (London).

9 "On the Behaviour of the Sulphur in Coke in the Blast Furnace." By Prof. F. Wüst, Ph.Dd., and P. Wolff (Aachen)

Reports on research work carried out during the past year will be submitted by C. O. Bannister (London), J. Dixon Brunton (Musselburgh), H. C. H. Carpenter (Teddington), J. C. Gardner (Oldbury), G. Dillner and A. F. Enström (Stockholm), E. G. L. Roberts and E. A. Wraight (London), Frank Rogers (Cambridge), and Walter Rosenhain (Birmingham)—Andrew Carnegie Research Scholars.

Members who intend to take part in the discussions will, on notifying such intention to the secretary, have copies of the papers forwarded to them a week in advance, as far as that may be found possible. Visitors' tickets will also be forwarded upon application.

By the courtesy of the Great Western, the Midland, the Caledonian, the London and North-Western, the Great Northern, the Lancashire and Yorkshire, the Great Central, and other railway companies, special arrangements have been made enabling members attending the meeting to obtain return tickets on payment of a single fare and a quarter on production of a certificate of membership, which may be obtained at the institute offices.

## FORTHCOMING EVENTS.

FRIDAY, APRIL 7.

**Royal Institution.**—At 9 p.m., "American Industry," by Mr. Mosely.

**Institution of Electrical Engineers (Manchester Students' Section).**—At 7.30 p.m., "Electric Cranes," by Mr. Jennison.

SATURDAY, APRIL 8.

**Birmingham Electric Club.**—At 7.30 p.m., "Lightning Conductors," by Mr. W. H. Whitehouse.

MONDAY, APRIL 10.

**Institution of Civil Engineers.**—At 8 p.m., Thirteenth "James Forrest" lecture, entitled "Unsolved Problems in Electrical Engineering," by Colonel R. E. B. Crompton.

**Institution of Mechanical Engineers (Graduates' Section)**—"Commercial Vehicles Propelled by Internal-Combustion Engines," by Mr. Edwd. Reeve.

TUESDAY, APRIL 11.

**Institution of Electrical Engineers (Manchester Section).**—At 7 30 p.m., annual general meeting. Mr. J. F ith will read a paper, entitled "Labour-Saving Formulæ in the Design of Direct-Current Dynamos."

**Institution of Electrical Engineers (Glasgow Section).**—At 8 p.m., author's reply to discussion on "Earthing," by Mr. W. W. Lackie; paper by Mr. H. Watson, entitled "Fittings."

WEDNESDAY APRIL 12.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m., "The Measurement of Resistance," by Mr. A. Cunnington.

THURSDAY, APRIL 13.

**Royal Institution.**—At 5 p.m., "Synthetic Chemistry," by Prof. R. Meldola.
